With high-pressure inactive gas as working medium, the packing machine works at 4MPa. Safe yet causing no pollution, inactive gas could be emitted into the atmosphere directly after used, which make collecting devices unnecessary. Prior to work, the inactive gas should be stored in the energy accumulator, thus the parachute could be packed even without power. Fig.6 shows the pneumatic schematic diagram.

Conclusion

The following merits are found when the new parachute packing machine driven by high-pressure inactive gas is applied in a certain airport.

1) The modular design in the new machine facilitates daily maintenance and repairmen.

2) The pressing instrument could revolve around the axis of rotation, benefiting the loading of drag parachutes into the racket.

3) The application of high-pressure gas as working medium makes pneumatic motors and fuel tanks unnecessary, which renders the machine small in size, light in weight and cheap to manufacture.

Keywords: PMAC Motion Controller. FANUC. G-code.

Abstract. PMAC motion controllers serve not only as a receiver of the orders from CNC systems of many kinds, but also as a controller of the motion of machine tools' axles. With G83 as an example, a code commonly seen in the processing cycle of deep holes in CNC machining centers, it is advisable to come up with a method to write a special set of subprograms to invoke PMAC motion controllers with the application of G-code. Based on the method, case programing and machining simulation can be launched. Experiments justify that the method obtained can realize the compiling of fixed cycles with the use of G-code and, in turn, boast substantial significance in the development of open CNC processing machine tools.

Introduction

By a CNC machine is meant the device which can perform automatic and efficient procession according to the machining programs compiled in advance. As a general-purpose machining language, G-code is applied to carry out NC programs, so as to realize the precise motion of all feed shafts. The Turbo PMAC2-Eth-Lite controller is a low-cost PMAC designed by Delta Tau cooperation, which enjoy the merits of integration and extraordinary control performance. Introducing the Turbo PMAC2 CPU, the controller is equipped with 4-axis servo or step controls and 32 general digital I/O points. Moreover, the application of Ethernet and serial COM ports, based on the standard, offers a convenient method for the users to connect the controllers and upper computers and to decide whether to active the expansion function of the channel servo and I/O ports in the expansion cards of the shaft [1]. The probe into open CNC machining tools would be of great practical significance with the cyclic code for deep hole working as example which is commonly employed in the CNC system in the processing center.

Analysis of G83 in Procession Center

In the processing center, particular cycles of processing operation have been typified, for instance, drilling or boring a hole, which is realized by positioning the hole, fast forwarding, machining, fast back warding, etc. Typical machining actions have already programmed in advance and stored in the internal storage. When some action is required, the corresponding G-code would be invoked directly from the internal storage, which simplifies the process of programming.

The fixed cyclic G-code usually found in the CNC system in the processing center primarily takes on as the following program format: data type, reentry-point plane, type of hole machining, data of the hole position, data of hole machining, cycle index [2]. Considering, data types (G90 or G91) have been determined when the program works, it is unnecessary to mention them in the format of the fixed cyclic programs [3]. With the cyclic code (G83) for deep hole working as example, the code writes in the format as follows:

G98（G99）G83 X_Y_Z_R_ P_Q_ F _ K _

In the format, the first G-code (G98 or G99) stands for that for the reentry-point plane, among which G98 represents the initial reentry plane and G99 does the initial plane for R-point. With X and Y indicating the position of holes, Z is the coordinate value of Z, the bottom of the hole, and R is the coordinate vale of R, when the program is written absolutely. However, Z equals the distance from Z, the bottom of hole, to R stands for the distance from R to the initial point, and when the program is written inclemently. P means the pause time, during which the chopper stays at the bottom of the hole, Q does amount of feed every time, F does the speed of drilling, and K does cycle index. The fixed cyclic processing program, or G83, works as is illustrated in Fig. 1.

The tool will be quickly positioned to the places X and Y stands for respectively, and then positioned quickly to R. After drilling downward by the distance represented by Q (Q should dwarf zero, emerging as increment) at the feed rate equal to F, the tool is to return R quickly. Then, after quick position to the place, with the distance of d (determined by the internal parameters of the system) above the lowest point in the proceeding procedure, the tool shall drill downward by Q+d, and quickly return to R. The procedures above shall be performed repeatedly until the bottom point represented by Z is reached. When “d” symbolizing the creep feed of tools, it is by the internal parameters of the system that the distance is set between the point at which the descent of tools is switched from the mode of fast to cutting feed and the other one at which the proceeding mode of cutting feed takes place[3].

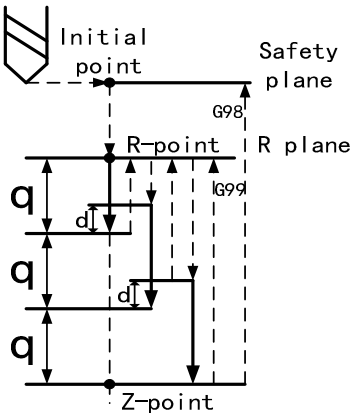

Fig. 1 Processing Fixed Recycle of G83

Development of G-83 Program

Turbo PMAC Clippe is able to compile RS-274 programs and operate G-code programs directly. Working according to its standards, users will get a flexible access to the creation and operation of various programs [5]. The value can be a constant or an expression in the programs, which emerge as a computing and logistic structure and resemble operating languages of the machine when figuring out problems of complex structure [4]. DeltaTau cooperation provides a small number of simple operation G-codes. Employing G-code as subprograms, PMAC, when coming across an operation program with the letter of definite value, would take it for granted that the program employs the orders of “1000.nn000”, and the values (say, X1000) following the line where “nn000” appears would be viewed as parameters, a phenomenon commonly found when dealing with a fixed cyclic program or a executable subprogram without any variables. In the case of meeting a return statement halfway, PMAC would return to operate the program employing the subprogram and carry out the rest orders as it would when dealing with a static G-code [4]. The codes representing subprograms can be omitted and be considered standard G-codes of the equipment when applied by the users. To write the G-codes with more fixed recursion instructions, what the manufacturers need to do is come out with the procedures according to which the subprograms is to be conducted. Fig.2 illustrate the procedures required to write G-83, the deep-hole processing recursion code usually employed in the CNC system of the processing center.

The key code is as follows:

```
undefine all
&1
#1->2000x
#2->2000y
#3->200z
#define farg       Q106

g00    x 0  y 0
close
```

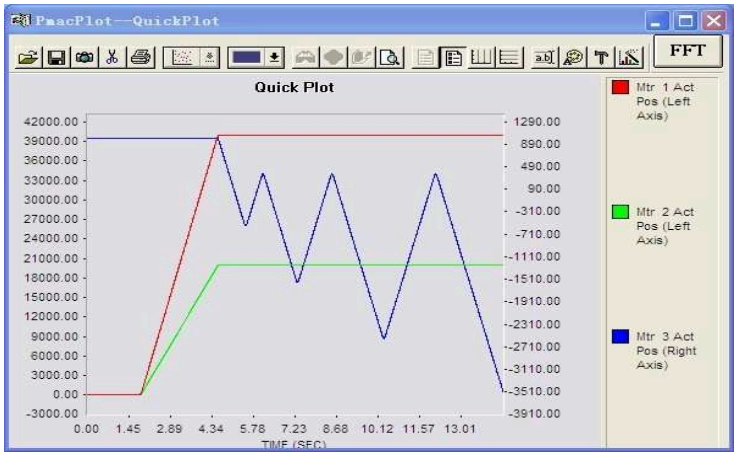

Fig. 3 Show the trajectory data collected.

Summary

The paper tries to develop an open CNC system based on PMAC motion controller. With as example G83, a deep-hole procession recursion code usually employed in the CNC in the processing center, the author probes into the code itself and combines precise algorithms with G-codes necessary to employ the peculiar subprograms of the PMAC motion controller. Experiments show that G-codes can be compiled to realize the fixed recursion instruction and enjoy high practical significance in developing the open CNC machining tools.

Keywords: $PM_{2.5}$; Automatic film-changing mechanism; Sampler

Abstract. The problem of air pollution is very serious now, so it is important for developing a monitoring mechanism of $PM_{2.5}$. An automatic changing film mechanism is designed and manufactured in the paper. Then static stress, vibration analysis and structural optimization are carried out by Solidworks software. Experiments show that the mechanism of $PM_{2.5}$ is reasonable and reliable.

Introduction

Environmental problem is common throughout the world. Since the quality of the air has a direct link to the health of human beings, air pollution draws our supreme attention. Among all the pollutants, $PM_{2.5}$ affects our health most, which grants the monitoring of the $PM_{2.5}$ top concern from China [1]. At present, China mainly relies on imported devices to implement the monitoring and analysis of $PM_{2.5}$ [2].

On the international level, the federal methods of equals and of reference is commonly used to monitor $PM_{2.5}$, with the former made up of spectrometry of light scattering, Beta ray method, light turbidity method of Beta rays and oscillating balance method. Relatively speaking, the latter method renders a more accurate description of $PM_{2.5}$ concentration in the air [3]. Based on the method of reference, the $PM_{2.5}$ automatic sampler is designed to collect the fine particles of $PM_{2.5}$ in the air. The automatic film-changing mechanism in the sampler can automatically, rapidly and accurately replace filter membrane holders in the place where to collect the particles, a feature presenting the difficulty as well as the key of the whole device [4][5].

$PM_{2.5}$ Automatic Changing-film Sampler

A $PM_{2.5}$ automatic changing-film sampler is meant a device that can precisely collect $PM_{2.5}$ particles floating in the air, which can be applied to the unmanned monitoring over an extended period. With the help of the PM_{10} inertial impact cutter and $PM_{2.5}$ whirlwind cutter in the device, $PM_{2.5}$ particles can be screen out and transported upon the quartz films at a constant rate of flow. When the film is used up, a second one would be employed to serve the collection. Once the whole collecting process is completed, the obtained particles shall be weighed and the dense of $PM_{2.5}$ would be acquired based on the data. Fig.1 illustrates the $PM_{2.5}$ automatic changing-film sampler.

Composition of Automatic Film-changing Mechanism

Automatic changing film involves a relatively complicated series of movement. That is to say, each movement has a chance of impacting the film changing and in turn influence the dense of $PM_{2.5}$ obtained. Therefore, all the movements should be implemented precisely so as to guarantee the quality of film-changing and accuracy of samples. Fig.2 shows the detailed composition of the automatic film-changing mechanism.

Fig.1 $PM_{2.5}$ Automatic film-changing sampler

The automatic film-changing mechanism should be installed at the center of the sampler. The whole mechanism is composed of the loading buckets, storing buckets, working cylinders, pushing cylinders, rodless cylinders, grippers, enclosure of aluminum foil and relevant accessories. A manipulator consists of the rodless cylinders and grippers. With rubber tail margins attached downward to lessen the pressure, the aluminum trunk envelops the majority of the mechanism. The loading bucket and storing bucket, to accommodate the box of filtering films to collect particles and having collected particles respectively, resides at the bottom of the trunk. Powered by the air from the air pump, the plungers residing in the buckets could drag the box of films downward and upward. Considering the complex composition of particles in the air, including some corrosive substances, say, nitrates and sulfates, the seal ring of the plunger should be made from silicon rubber, which has a good corrosion protection, covered by tetrafluoroethylene.

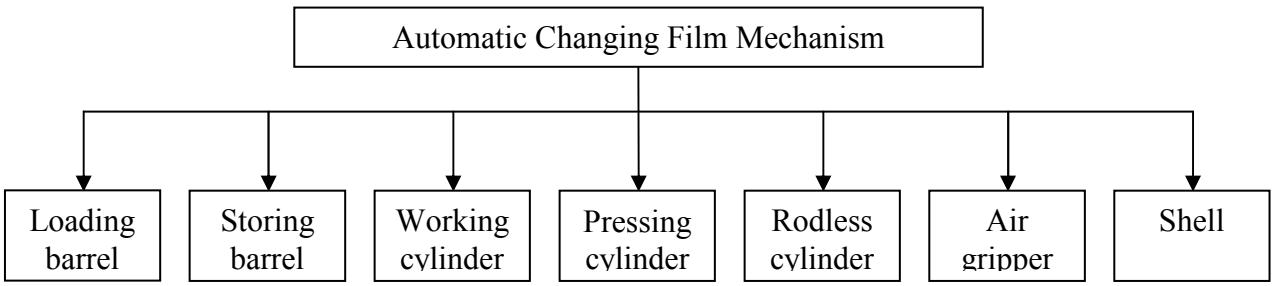

Fig.2 Composition of automatic film-changing mechanism

When the mechanism is started, the manipulator will move to the loading position, making preparation for the loading of film boxes. Once the magnet switch detects the manipulator has reached the targeted position, the two position three way solenoid valve, controlling the loading bucket, would be switched on and the plunger in the loading bucket will drag the box of films upwards until it reaches the loading position sensed by the switch. Then the manipulator will clamp the box to working position. When the box reaches, the manipulator gets loose and the working cylinder pushes upwardly, leaving 2 V-shaped seal rings clamping tightly the box. Then the collecting process can be launched. When the process ends, the working cylinder pushes downwardly, leaving the 2 V-shaped seal rings downward. The manipulator, afterwards, drags the box of collected films to the storing position. Pushed downwardly by the pushing cylinder, the box arrives in the storing bucket, waiting to be analyzed.

Optimum Structural Design

While working, the automatic film-changing mechanism is primarily influence by the gravity and vibration. Based on the analysis of static stress and vibrational frequency upon the mechanism with Solidworks simulation, we can optimize the structure and material of the mechanism. The process of optimizing runs as follows:

Create diffsets. Employ the plug-in of simulation in Solidworks to create diffsets. Make use of the analysis of static stresses.

Choose materials. Define the material characteristics of each accessory respectively. If no restriction exists, define the coordinating settings of the accessories in the modeling.

Choose clamps. Based on the working condition of the mechanism, define the restriction of clamps so as to ensure the applicability of the clamps in the mechanism.

Adding external loads. Since the mechanism merely works under the influence of gravity, the load added should equals the gravity ($9.81 m/s^2$) , and the temperature should be set as the average working temperature (20 ℃).

Construct grid models. Based on the complexity of the mechanism, define the parameters of the grid as follows: as for grids based on curvature, the unit falls into the range from 0.2mm to 5mm. The number of minimum units in the cycle is 8, with the rise ratio over a unit equal to 1.6 and Jacobian point set to 4.

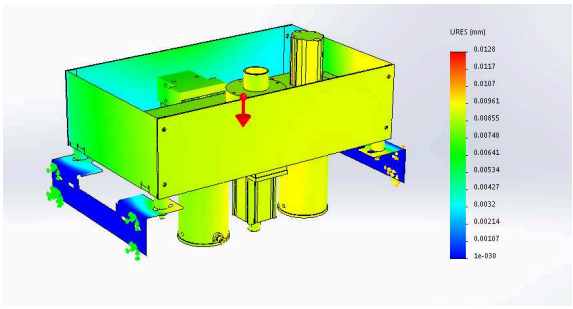

Fig.3 Displacement analysis of static stresses

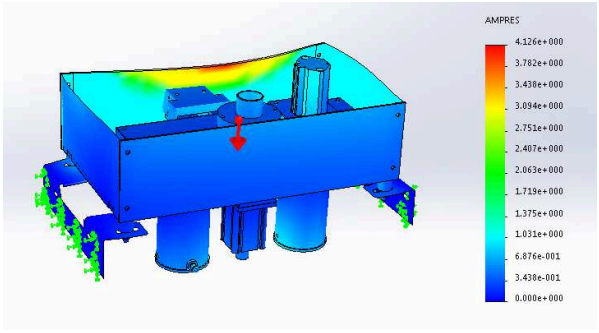

Fig.4 Analysis of frequency

The analysis the static stresses indicates that the maximum static stress upon the mechanism is about 2Mpa, strain about 0.00002747, and maximum displacement of static stress about 0.01mm. In effect, the aluminum product employed in the mechanism boasts a yield strength of about 80 Mpa and the mechanic precision of the whole mechanism reaches about 0.01mm. The simulation proves that the structure of and material adopted in the mechanism meets the requirements of static stresses.The analysis of frequency resembles that of static stresses. Please refer to analysis of static stresses to land the process of setting. Fig.4 shows the outcome of the analysis.

The vibration of the mechanism originates mainly from the air pump. The analysis demonstrates the point with the greatest amplitude lies at the back of the aluminum trunk, with the head cover out of concern. The existence of the head cover can lessen the vibration of the trunk and decrease the amplitude significantly.

Based on the analysis of static stresses and frequency, under the influence of gravity and vibration, the chosen material and structure could ideally satisfy the working requirements.

Experimental Analysis

Table 1 gives a contrast of data observed by 3 devices located in the top building of the monitoring center of Tianjin environmental protection agency (with a height of some 20 meters, E: 117°09′04″, N: 39°05′49″). One is the $PM_{2.5}$ automatic film-changing sampler, another is the Partisol 2025i-D sampler, and the other is β-ray $PM_{2.5}$ online monitor.

Seen from Table 1, the 1st two devices employ the federal method of reference and the last device makes use of light turbidity method of Beta rays. The data obtained shows that the error rate of the 1st and 3rd devices reaches about 0.03, while the 2nd falls in the order of 0.03, a much better figure over those of the other two devices. The difference can be traced back to the fact that, with the federal method of reference, the dense of $PM_{2.5}$ worked out bases on the factual data while the method of Beta rays figures out the dense of $PM_{2.5}$ based on the degree of attenuation of rays. Thus, the federal method of reference renders a more accurate outcome. A relatively small difference exists between the data of the sampler and the Partisol 2025i-D sampler, a fact justifying that the automatic film-changing sampler is designed reasonably and satisfies the working requirements.

Table 1 Contrast of experimental data

Devices \ Date	2014.4.14-15	2014.4.15-16	2014.4.16-17
$PM_{2.5}$ automatic film-changing sampler	0.076873916	0.060727725	0.127249365
Partisol 2025i-D sampler	0.076682028	0.061124732	0.126909091
β-ray $PM_{2.5}$ online monitor	0.072456467	0.059521739	0.125391304
The error rate of the Comparison with partisol 2025i-D sampler	0.002502385	-0.006495034	0.002681242
The error rate of the Comparison with β-ray $PM_{2.5}$ online monitor	0.061061638	0.020261263	0.014818101

Conclusion

The paper gives a detailed description of the principle of the pneumatic automatic film-changing sampler of $PM_{2.5}$, renders a finite element analysis of setting processes and data, and finally implements a contrast with other devices recognized by the country through an experiment. The test indicates the outcome lies the accepted range. Basically meeting the national standards, the sampler can play a competent role in monitoring the dense of $PM_{2.5}$.

Keywords: Disaster Rescue Robot. Shock-absorbing System. Geometry design. Performance analysis

Abstract. Disaster Rescue Robot is a small caterpillar robot used for carrying first aid articles, reasonable shock-absorbing system is an indispensable part to reduce the rush of the ground because it has to plummet from a certain level to the ground when it works. We use the method of modular design in this article and design the landing gear based on the performance of conical spring in order to absorb some of the forces during a fall. Then the three-dimensional modeling software is used to establish the parametric model of the robot shock-absorbing system to provide an effective way for the design of the Disaster Rescue Robot.

Introduction

More than 70 percent of Chinese cities and more than 50 percent of the Chinese population are located in areas vulnerable to serious earthquakes, or meteorological, geological or marine disasters [1]. Chinese people's lives and properties and economic and social development suffered very heavy losses during major natural disasters happened over the years. Disaster Rescue Robot is a small caterpillar robot used for carrying first aid articles, and it integrates many advanced multidisciplinary fields such as mechanical engineering, electronic technology, intelligent control and computer science research. In the military field it can be used for battlefield reconnaissance, break the barrier and tracking target designation or entering into the nuclear, chemical and biological pollution area to carry out combat mission, connect the signal or provide precision strike against the enemy. In the field of public safety it can be used in security monitoring, explosion-proof, anti-terrorism, emergency rescue, disaster relief, and acts as an intelligent transportation [2].

Disaster rescue robot mainly completes the information acquisition of the disaster environment. In this article, we use the method of modular design which has the advantage of convenient disassembly and maintenance, adapt complex pavement, and by the rotation of the swing arm before control module to adjust the robot's posture change to auxiliary climbing obstacle and across the ditch [3]. Robot will have perfect environmental adaptability, motor skills and resist impact from the drop of a certain height after reasonable structural layout and design. We conduct the detailed engineering design of the robot not only on the aspects such as the principle, performance and organization of the movement and anti-throw structure and so on several aspects of research, but also combined technology with the modern theory of mechanical design, optimization method, new materials.

Performance analysis and design of the Disaster Rescue Robot

A lot of critical questions include precise and safe landing, remote wireless communication, flexible mobile in ruins, anti-seismic waterproof and fireproof need to be solved to design a special robot system that can be dropped into the disaster areas by the plane to get information of the disaster and carry out emergency rescue. According to the function, the robot system can be divided into landing control system umbrella, soft landing machine, remote wireless communication, intelligent control

and robot ontology modules, etc. The design of the detection robot which can walk on the ground includes the flexible mobile design to travel on the ruins; the reliable design of anti-seismic waterproof and fireproof in the disaster environment; the ability to carry sensors, communications equipment and emergency supplies [4].

In condition, general design requirements for robots act as the followings:

1). The total weight of the robot is less than 50kg, the movement speed is more than 10m/min, the working time can last more than 1 hour, and the remote control design to travel on the ruins flexibly. The robot can also load all kinds of detection devices and emergency supplies.

2). The wireless communication distance of remote control should be more than 10km to make sure the reliable transmission of the image, noise and various sensors and control signal.

3). The robot has to have the characteristic of anti-seismic waterproof and fireproof, etc.

4). The robot should have good capability of riding over obstacles obstacle, be suitable for all kinds of disaster

The argument about the robot's shock-absorbing scheme

The design of the shock-absorbing system mainly adopts the spring suspension method which can produce large elastic deformation under the load [5]. According to the differences of the load, spring can be divided into tension spring, compression spring, torsion spring and bending spring. According to the shape of the spring, spring can also be divided into helical spring, ring spring, belleville spring, flat leaf spring, coil spring and so on.

The basic formula of spring:

1) The formula of strength calculation

$$d = 1.6\sqrt{\frac{KFC}{[\tau]}} \tag{1}$$

K stands for curvature correction factor， $K = \frac{0.615}{C} + \frac{4C-1}{4C-4}$；

F stands for load；**C** stands for spring index，**C=D2/d**；**[τ]** stands for the allowable twisting stress of the spring material. Then the diameter of the spring wire ***d*** can be computed.

2) The formula of stiffness

$$n = \frac{Gd^4}{8FD_2^3} = \frac{Gd\lambda}{8FC^3} \tag{2}$$

n stands for the effective coil number of the spring; **G** stands for the shear modulus of the spring; **λ** stands for the deflection of the spring; $\mathbf{D_2}$ stands for the medium diameter of the spring ring; the other symbolic significance has the same meaning as previous.

3) In order to limit the spring load, the stability formula **F** is less than the instability of critical load **Fcr** in the stability formula. We generally take F=Fcr/(2 ～ 2.5) and the critical load $F_{cr} = CB \cdot k \cdot H_0$,CB stands for instability index.

After the demonstration, the conical spring is adopted as the mainly spring suspension of the Disaster Rescue Robot as Fig. 1 shows.

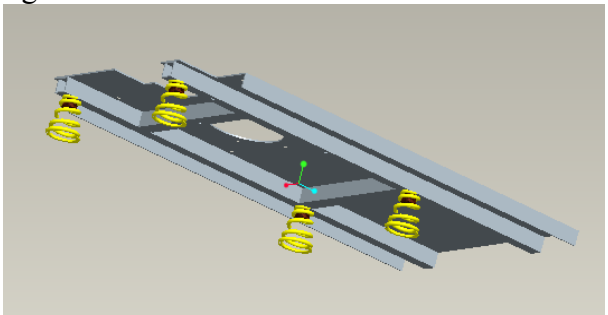

Fig. 1 Spring suspension system

Geometry design of the spring suspension

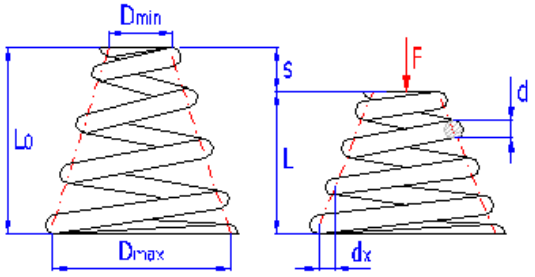

Fig. 2 The dimensions of the conical spring.

Fig. 2 shows the conical spring used in the shock-absorbing system of the robot. Four conical springs made of the materials of 65Mn are used. The small diameter $D_{\min}$ takes 20mm, big diameter $D_{\max}$ takes 60mm, L_0 takes 60mm, M takes 30kg.

$$F_c = \frac{L_0 - L_s \cdot G \cdot d^4}{8 \cdot n \cdot D_{\max}^3} \tag{3}$$

The conical spring is made of spiral coil, and the gap between the work coils is constant to absorb the axial external forces. The coil spring whose wire diameter is about 6mm is cold forming. The thermal forming spring must be used for high load of products whose wire diameter is greater than 10mm.The conical spring is used in the condition that the spring coefficient changed along with the compression quantity. Increased along with the conical spring compression, the adjacent working coil contact gradually (The first coil diameter is the largest). Then the compression deformation of the coil is no longer involved in deformation resulting in spring coefficient increase gradually. The work characteristics can be divided into two areas [6].

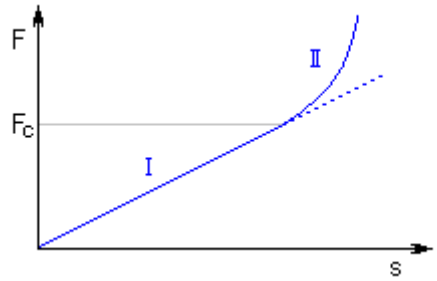

Fig. 3 Basic relations of the conical spring calculation

1) The linear work area (the spring constant is constant) F<FC
2) Incremental feature work area- After contacting with the first largest coil F>FC

The decisive factor of the limiting force FC is the space between the coils p that also means the size of the length of free spring. The limiting force FC has a positive relationship with the length of spring and the linear spring coefficient.

Coil bending causes additional coil bending stress, therefore the correction coefficient is used to correct the pressure. The correction coefficient of the coil springs with circular section is determined by Formula (4).

$$K_s = 1 + \frac{0.5}{c} \tag{4}$$

The correction coefficient of springs with square section is determined by the given proper nomogram of spring diameter ratio b/h. Coefficient of the status quo has been included in the correction calculation.

Considering the several different design closure of compression spring, closing coil is the end coil of the spring and has the same axle with working coil. Its angle and the spacing won't change when the spring works. Closing coil is usually used as the braced and stayed surface of spring and finish on

both ends is the most often used in compression spring. The grinding flat coil is the end of the coil, and it is processed to a plane perpendicular to the axis. It lasts from the three quarters of half edge processing coil to the open end. The diameter of the spring used in the grinding flat coil is usually more than 1mm.

The shock-absorbing system of the disaster rescue robot has four supporting points and each point fixed with a taper spring (The tolerance of the taper spring is 5Kg.). The taper springs are the most important part of the shock-absorbing system. The size of the conical spring showed in Table 1 is calculated by formula (3) and (4).

Table 1 The size of the conical spring

Spring diameter ratio $\mathbf{C_{min}}$	min.3
Spring diameter ratio $\mathbf{C_{max}}$	max.20
Diameter $\mathbf{D_{max}}$	max.40mm
Ratio $\mathbf{D_{max}/D_{min}}$	min.2
Number of working coil **n**	min.2
Ratio **b/h**	5:2
slenderness ratio $\mathbf{L_0/D}$	2/5

Summary

Through the design of the robot body, we discussed several forms of the shock-absorbing system, designed and selected the shock-absorb system and the spring suspension system was found. We also discussed the relationship of the two working areas and the design and calculation is on the basic of it. The function of anti-seismic has proved by experimental research.

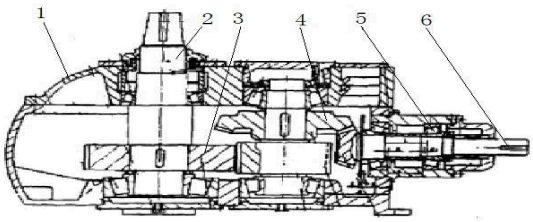
Keywords: Cooling Tower Fan Gearbox. Failure Analysis. Preventive Measures

Abstract. To avoid fatal accidents caused by premature gear failure of cooling tower fan, research and analysis of gear tooth surface pitting and tooth breakage which are the two main failure forms of cooling tower fan gear are conducted in this article, the specific reasons of the fan gear failure are got, and corresponding suggestions of improvements and preventive measures are put forward, this can be taken as reference to the gear design and fault analysis.

Introduction

Cooling tower fan widely used in petroleum, chemical, electric power industry, carries industrial water circulating cooling function and its operational status directly affects the industrial production. The fan reducer deliveries rotary rotation from the motor to the fan impeller by a pair of spiral bevel gears and a pair of helical cylindrical gears, level input and vertical output as showed in figure 1.



1. Box 2. Output shaft 3. Cylindrical helical gear 4. Spiral bevel gear
5. Bearing 6. Input shaft

Fig. 1 Cooling tower fan drive structure

The premature gear failures directly affect the fan working reliability and efficiency; In engineering applications, some domestic cooling tower fan reducer gear appear tooth surface premature failure and frequent teeth broken conditions after only working three to five months, especially more severe in high temperature area and summer. The failure analysis was aimed at identifying the root cause of the gear damage in order to prevent their recurrence[1-3].

Cooling Tower Fan Gear Failure Form and The Reason Analysis

Gear Tooth Surface Pitting Analysis. In a overhaul of cooling tower fan gearbox in a petrochemical plant, it is found that different degrees of pitting exist on gear, Fig. 2-1 and 2-2 show helical gears tooth pitting, high density of tiny pits distribute uniformly on the low tooth surface near the pitch line, and numerous micropittings will be seen after magnifying the damage surface[4-5].

Fig. 2-1 Active helical gear tooth pitting

Fig. 2-2 Passive helical gear tooth pitting

Focus on the helical gears pitting situation, failure judgment on gear pitting is made, then we declare that the gear is failure and should be discarded. Through examination and final analysis, we get the root reasons of pitting are as follows.

1) During cooling tower fan gear operation, cyclic contact stress will generate on meshing surface of helical gears ,because the additional load and gear partial load caused by unbalanced moment of inertia of the blade, the load that gear bearing will increase, After certain cycles, the tooth surface contact stress exceeds the fatigue limit of the material, which will make the gear surface and sub-surface crack under the effect of fatigue, the cracks expand and extend, eventually metal bits shed from tooth surface.

2) The transmission power of cooling tower fan gear is large while the meshing contact surface of helical gears and spiral bevel gears both are wide that the oil temperature likely to rise easily so the oil prone to failure due to oxidation, poor lubrication is liable to happen and effective lubricating film is difficult to form, which finally cause gear pitting.

Gear Tooth Breakage Analysis

Analyzing gear tooth broken failure of the cooling tower fan reducer, it is found that most of the gear tooth broken of helical gear and bevel gear are usually local broken. In a recent cooling tower fan speed troubleshooting, we found severe tooth broken on active bevel gear upon input shaft and rough fracture morphology,1/3consecutive face cutting on driven spiral bevel gear, as shown3-1 and 3-2 figures.

Fig. 3-1 Active spiral bevel gear tooth broken

Fig. 3-2 Driven spiral bevel gear tooth broken

Figure 3-1 shows the active spiral bevel gear tooth end breakage, through macroscopic examination, it is found that active tooth cracked from bottom and fractured to the concave of root, which is evidently due to strength insufficient of the tooth root. The obvious destructive pitting and spalling in the fractured tooth indicate the presence of partial load condition which cause partial overload of gear and make the tooth surface contact stress much higher, this is the main reason of gear tooth broken. Figure 3-2 displays the driven spiral bevel gear teeth broken; the driven gear

failure mainly appears in gear meshing area above the pitch circle, which should be caused by a huge impact the moment driving gear broken in meshing area.

Due to assembly errors, the misalignment error of two bevel gears cone top is too large and work cone distance is inconsistent to the design, so the meshing bevel gears contact on gear small end. And because the input shaft connected to the active bevel gear shaft is longer, linear deviation is easily produced, which caused unbalanced gear running.

Measures To Prevent Premature Gear Failure:

General Measures. 1) Choose the larger module gear within the scope of the permission to improve the gear tooth root bending strength. Choose larger diameter gear with the smaller curvature of involute for reducing the contact pressure .Considering the larger vibration and impact of cooling tower fan gear, the selected safety coefficient should be greater than the critical value.

2) Reduce surface roughness through tooth surface gear lapping; improve the heat treatment and chemical heat treatment, ensure enough hardness of surface layer and core.

3) Use appropriate adjustment sheet adjust installation distance in spiral bevel gear assembly to get good lateral clearance and contact area; Because of the speed reducer input shaft is longer, the balance of shaft and gear should be proofread after right installation.

Lubrication and Lubrication Management

Gear pitting and tooth fracture of cooling tower fan are closely related to the lubrication. In gear using, reasonable lubrication can prevent the occurrence of early pitting, suppress and mitigate the development of pitting. Proper gear lubrication management is essential to ensure gear to achieve the desired working life.

1) Lubricating oil viscosity changes with external conditions (pressure and temperature), in order to ensure the viscosity stability of lubricating oil ,we suggest operators observe the change of the viscosity of gear lubrication oil regularly and replace lubricating oil when viscosity rise or fall 15%.

2) Cooling tower fan gear works in continuous operation at full load in summer, which cause serious fever, while works in intermittent operation and light load conditions in winter. So different specifications of the lubricating oil should be changed according to different seasons, we recommend use low viscosity oil in winter, high viscosity in summer.

3) Pay attention to the oil cleaning and change gear lubrication oil according to the maintenance cycle. If impurities entering the gear work surface, it is not only can destroy the film, but can also cause abrasive wear, so operators must pay attention to the cleaning of lubricating oil.

Other Gear Failure Preventive Measures

1) Take regular care and maintenance of gearbox, including wheel surface, bearings, housing, fasteners, oil seals, etc.

2) Monitor cooling tower fan gearbox running status, such as temperature, pressure, noise, vibration, etc. When abnormal phenomena occur, stop the device promptly to avoid major accidents.

Summary

Through analyzing gear tooth surface pitting and tooth breakage, two main failure forms of cooling tower fan reducer gear, corresponding preventive measures and correct repair process are put forward. Proposal of lubrication, lubrication management and other auxiliary measures to prevent premature gear failures are given. The above schemes are important for the cooling tower fan frequent failure status caused by faulty gear.

Keywords: Viscous pressure forming(VPF). Super-alloy. Thin-walled part with variable diameters. Corrugated thin-walled part. Asymmetrical thin-wall part with variable diameter

Abstract. Viscous pressure forming(VPF) is a new developed sheet soft-punch forming process in 1900s. The basic principle and characteristics of VPF are described. The applications of VPF technologies of nickel-based super-alloy corrugated thin-walled part, asymmetrical thin-wall part with variable diameter, super-alloy thin-walled part with variable diameters, corrugated thin-walled part with larger diameter and small section are presented. The results show that VPF is suitable for the forming of parts with high strength, low plasticity, super thin-wall and complex shaped.

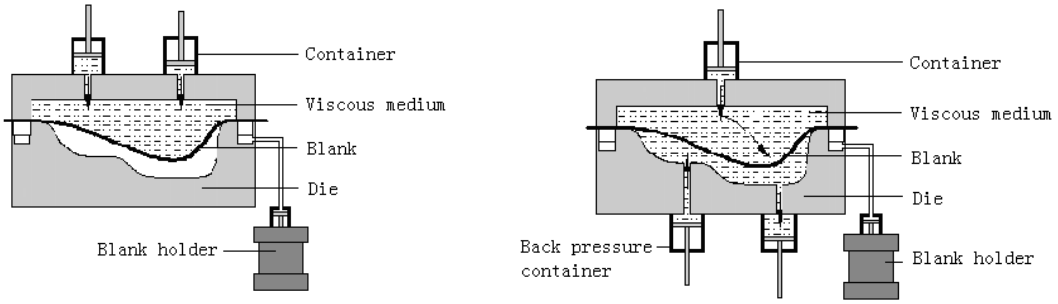
Introduction

Development with the modern industry, more sheet metal parts with very complex three-dimensional shape are made with high strength, difficult-to-deform and super thin-sheet materials in the industry of present aeronautics, astronautics, automobile, chemical and other high-tech industries. The requirement to these parts in dimensional accuracy and surface quality, especially wall-thickness uniformity, becomes higher and higher. So the more advanced the forming technology is needed. The usually flexible-die forming technology and conventional stamping method has its own application range. But because of its good characteristics, viscous pressure forming(VPF), which makes use of a kind of viscous material as pressure carrying medium, has good perspective[1-3].

Principle and characteristic of VPF

VPF was invented by M. L. Rhoades and L. J. Rhoades in 1992[4], and is different from conventional flexible sheet technology, in that it uses a kind of semi-solid, flowable and viscous materials as the pressure-carrying medium. In VPF, the viscous medium is used as a soft punch when it is applied on one side of the sheet metal and used as a soft punch and back-pressure when it is applied on both sides of the sheet metal. Through the injecting of viscous medium, the pressure distribution is applied in the die-container and the sheet is formed under the pressure of the viscous medium. A schematic diagram of VPF is shown in Fig.1. Compared with the conventional sheet metal forming process, the viscous medium can fill a complex-shaped surface very well. The parts formed by VPF have good surface quality and high dimensional accuracy[5].

The tangential adhesive stress of the viscous medium has a key effect on the sheet metal in VPF. The sheet metal is subjected to the tangential adhesive stress of the viscous medium during the whole forming process. The value of tangential adhesive stress is affected by the viscous medium pressure, viscosity and forming time. However, the punch gradually makes contact with the sheet metal and the friction force is then related only to the surface quality of sheet metal and the rigid punch. Comparing the thickness of parts formed by VPF, rigid punch forming and hydro-forming with the numerical simulation method, the thickness of parts obtained by VPF is more uniform than that by rigid punch forming and hydro-forming[6-9].



a) Single surface loaded b) Double surfaces loaded

Fig. 1 Principle of viscous pressure forming

Applications of VPF

Application of VPF was developed by Leonid B Shulkin firstly. The geometry for the VPF test part "sub-inner panel" was developed based on a nozzle inner panel component currently produced by Pratt & Whitney (Fig. 2). And it was explained through finite element analysis method (Fig. 3) by PAM-STAMP. The FEM results are compared with experimental VPF results. The viscous medium "blow through" phenomenon between the blank holder and the sheet during VPF is described and quantified.

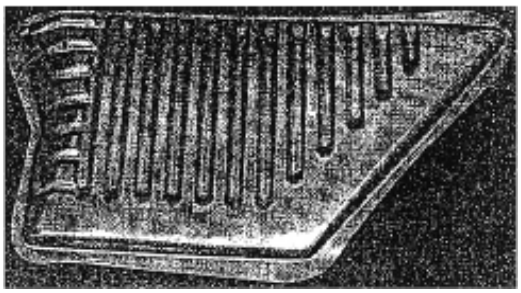


Fig. 2 Pratt and Whitney nozzle inner panel

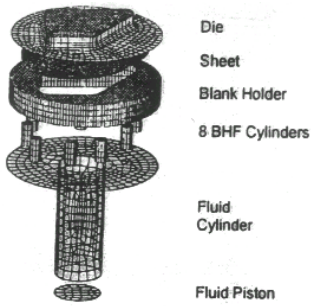

Fig. 3 FEM model for VPF simulations

VPF is used in the areas of aeronautics and astronautics successfully by Harbin institute of technology. A nickel-based super-alloy corrugated thin-walled part (Fig.4)[11], asymmetrical thin-wall part with a variable diameter (Fig.5)[12],thin-wall parts with variable diameter (Fig.6)[13] and thin-wall parts with larger diameter to thickness ratio and complex small section (Fig.7) were produced successfully. The nickel-based super-alloy corrugated thin-walled part is a typical large-dimension, thin-walled and complex-shaped part formed by VPF. The shape and the main dimensions of the corrugated thin-walled sheet part with small radius are shown in Fig.4. where the wall-thickness is 0.3 mm, the width is 81 mm, and the radius of all ripples with non-uniform depth is 2.3 mm. With rigid punch forming, the wall-thickness of parts would thin severely and the parts could even fracture at corrugated surfaces during forming. With rubber or polyurethane flexible punch forming, corrugated surfaces could not be formed to meet the requirements of dimensional accuracy due to this being beyond the deformation limits of rubber or polyurethane. With VPF, the dimensions of small radius corrugated surface can meet the requirements of dimensional accuracy.

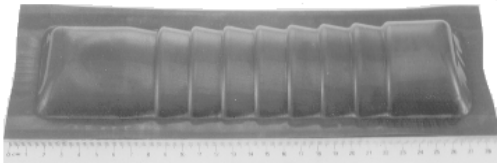

Fig. 4 A nickel-based super-alloy corrugated thin-walled part

The asymmetrical thin-wall part with a variable diameter is one of the typical lightweight complex construction components in aeronautics, astronautics and automobile industry. The traditional method to form this kind of part is by the way of forming each part separately and then assembling together by welding. Because of too many working procedure, it is difficult to control the forming quality, this method can't satisfy the increasing requirement of improving the properties

of forming parts. Aiming at the problems, a new no-seal tube-blanks forming technique is proposed, which pressure provided by the viscous medium. Because of the free in the circumferential direction of the no-seal tube-blank, sheet blank flow in the circumferential direction can compensate the deformation of the local forming area. This new technique increases the forming limit and provides a new way to form the asymmetrical thin-wall part with a variable diameter.

Fig. 5 The asymmetrical thin-wall part with a variable diameter

Tube-compression is one of the most typical forming methods for variable diameter parts. Because of compression instability, buckling and wrinkling easily come into being in tube-compression process, especially for the thin-wall parts, which restricts the applications of tube-compression. In order to solve problems in tube-compression of thin-wall parts with complex shape, by applying the viscous pressure forming (VPF) method in tube-compression, a new forming method, local tube-compression by VPF, is developed. Taking advantage of the mechanical property and easily loading mode of viscous medium, the occurrence of tube buckling can be delayed and the wrinkling can even be removed in a certain extent during local tube-compression process by VPF, which increase the diameter reduction limit. The new tube-compression method can be used in tube-compression of high strength materials and the precise plastic forming of thin-wall parts with larger variable diameter.

a) Preformed tube-blank b) The specimen of tube-compression c) Cross section of the specimen

Fig. 6 Thin-wall parts with variable diameter

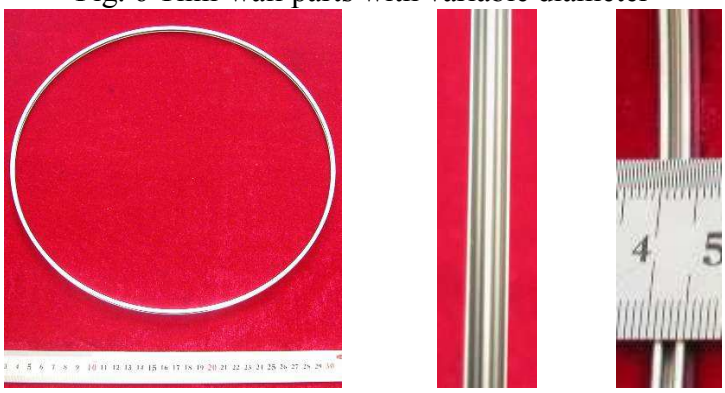

Fig. 7 Thin-wall parts with larger diameter to thickness ratio and complex small section

Thin-wall parts with variable diameter which have the characteristics of larger unit variable diamerer ratio (3.5~7.2), larger diameter to thickness ratio (500~1750) and ultra thin wall-thickness (0.2~0.3mm) are the important functional parts of new-type aerospace and power machineries. Meanwhile dimensional precision of the parts is higher and materials are heat-resistant alloy. During to the characteristics such as structure, wall-thickness and precision and so on, the cricital

techniques in the forming process is control of wall-thickness uniformity and dimensional precision, material flow, plastic deformation and stress distribution. For these problems, viscous adhesive stress between the interfaces and non-uniform viscous pressure has been taken full advantage; viscous quasi-bulk pressure forming was raised. In this method, the material flow has better been controlled, which can restrain the wall-thickness reduction and has the better stress distribution.

Conclusion

Compared with conventional sheet metal forming technology, VPF can improve the formability of sheet metal and the parts obtained by VPF have high surface quality and high dimensional accuracy. And the viscous medium can fill a complex-shaped surface very well. VPF is suitable for manufacturing high strength, low plasticity and difficult-to-form materials and complex-shaped parts. Meanwhile, VPF is suitable for forming multi-kinds, small quantity and promptly update products in the areas of aeronautics and astronautics. Viscous medium outer pressure necking uses semisolid, flowable, highly viscous and certain rate sensitivity super-polymer as pressure carrying medium which can solve wrinkling problem during necking forming effectively and increase necking limit of specimen.

Keywords: Sheet metal unfolding. Neutral plane. Pro/E

Abstract. There are a variety of sheet metal parts in rocket body structure. The exact length calculation of sheet metal structure work is the key to ensure better quality of product. This paper describes two methods of sheet metal part unfolding which are method of formula and method of software. Two quick unfolding ways using AUTOCAD and EXCEL are described aim at method of formula. Summarize the notes of using Pro/E to unfold aim at method of software.

Introduction

Sheet metal parts cover a large proportion of rocket body structure, and there are many species and different structure of sheet metal parts, and their production process will take bending forming method. Before forming sheet metal parts developed length should be calculated. With the rapid development of computer technology, widely used in automated processing methods, and urgent demand of rocket model development mission, sheet metal parts process method has greatly changed. Method of formula has low sheet metal parts unfolding accuracy and large computation, so this method is suitable to calculate parts which have low accuracy requirements and simple structures. Method of software has high sheet metal parts unfolding accuracy, can save raw materials and reduce the workload of manual trimming, so this method is suitable to calculate parts which have high accuracy requirements and complex structures, and commonly used software is 3-dimensional graphics software Pro/E.

Theoretical analysis of bending process

Length of neutral plane does not change in the bending process, so neutral plane is the standard of calculating developed length. But neutral plane does not coincide with geometric center plane of material thickness. When inner radius is large and bending angle is small, neutral plane is close to geometric center plane. When inner radius is small and bending angle is large, neutral plane moves inward [1-4]. In the actual production process, the position coefficient of neutral plane K is used to calculate curvature radius of neutral plane ρ:

$$\rho = R + Kt \tag{1}$$

ρ——curvature radius of neutral plane;

R——inner radius;

K——the position coefficient of neutral plane;

t——material thickness.

Method of formula

According to the principle that developed length is equal to length of neutral plane, just get the position of neutral plane, developed length can be got.

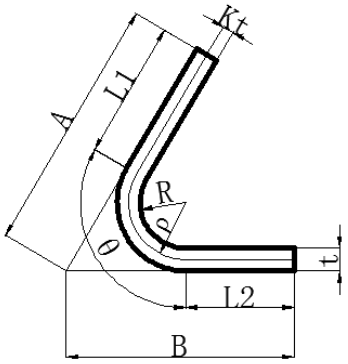

Fig.1 Schematic diagram of calculating developed length

Fig.1 is schematic diagram of calculating developed length.

Because the position of neutral plane is related to mechanical properties of the material, material thickness, bending angle, and inner radius, so it's difficult to get an accurate value of the position coefficient of neutral plane K. In the actual production process, empirical data is cited in calculating. Commonly used the position coefficient of neutral plane K is shown in Table 1.

Table 1 Common position coefficient of neutral plane K

R/t	K	R/t	K
1.0	0.32	3.0	0.40
1.2	0.33	4.0	0.42
1.3	0.34	5.0	0.44
1.5	0.36	6.0	0.46
2.0	0.38	7.0	0.48
2.5	0.39	≧8.0	0.5

After the appropriate value of the position coefficient of neutral plane K is selected, there are two quick unfolding ways in order to save computation. (1) Using AUTOCAD to draw sectional view of sheet metal parts, using the Shift function to make all inside edge of parts shift Kt to outside, and using the Polyline function to link all lines which are obtained by shifting. The linked line is neutral plane, so developed length can be measured quickly. (2) Using programming and computing functions of Excel, formula of calculating developed length can be programmed into the software, and let parts sizes be input parameters and developed length be output parameter. The interface for the calculation in Excel is shown in Figure 2.

Calculation in Excel					
parts sizes do not cover length of bend curve			parts sizes cover length of bend curve		
length:	L1=	4	length:	A=	10
length:	L2=	4	length:	B=	10
inner radius:	R=	4	inner radius:	R=	4
the position coefficient of neutral plane:	K=	0.5	the position coefficient of neutral plane:	K=	0.5
material thickness:	t=	2	material thickness:	t=	2
bending angle:	θ=	90	bending angle:	θ=	90
developed length:	L=	15.85	developed length:	L=	15.85

Fig. 2 The interface for the calculation in Excel

Method of software

Sheet metal module of Pro/E has powerful capabilities to unfold. Dimensional model of sheet metal parts should be built first, and using the Unbend function unfolding model of sheet metal parts can be got. There is essential difference between method of Pro/E and method of formula. Method of Pro/E is parametric and intelligent, and it is based on the simulation of sheet metal bending process to unfold. Through the unfolding model of sheet metal parts, Pro/E can direct output 2-dimensional drawings in various formats which can be directly applied to CNC cutting and punching devices[5-6]. Dimensional model and unfolding model of sheet metal parts in Pro/E are shown in Figure 3.

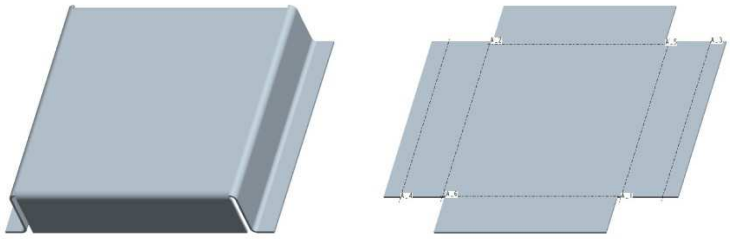

Fig. 3 Dimensional model and unfolding model of sheet metal parts in Pro/E

Before using the Unbend function to unfold, K-factor in Bend allow should be set up. It is worth noting that K-factor is equal to the position coefficient of neutral plane K, so K-factor is also an empirical data. Generally, in order to obtain the most accurate developed length, several sample parts are made firstly, and through measuring those pasts size, K-factor can be corrected.

Using Pro/E to unfold sheet metal parts, the following points should be noted:

1) Setting model environment: In order to make system of unit and view standard in Pro/E consistent with those used in CNC sheet metal equipments, model environment should be set before building dimensional model. Editing Config file or using Setup menu can change model environment.

2) Examine the dimensional model: Unfolding model is generated by dimensional model, so correctness of dimensional model should be ensured. Using Measure function or Model analysis function in Analysis menu can measure all key elements sizes. In addition process of sheet metal parts should be reasonable, otherwise Pro/E will refuse to unfold.

As can be seen that method of Pro/E has a lot of advantages, such as parametric, intelligent, quickly, high accuracy and paperless processing etc. So method of Pro/E adapt to the trend that sheet metal manufacturing develops toward CAD/CAE/CAM.

Summary

Through the introduction of this paper, both method of formula and method of software have advantages and disadvantages. Method of formula has low sheet metal parts unfolding accuracy and large computation, but it is easy to use. Method of software has high sheet metal parts unfolding accuracy, can save raw materials and reduce the workload of manual trimming, but it needs to skillfully use Pro/E. In addition, no matter which method is chosen, the position coefficient of neutral plane K is a key factor affecting sheet metal parts unfolding accuracy. So processors should correct K based on the actual sizes of sheet metal parts, and accumulate empirical data which is suitable to materials and equipments commonly used.

Keywords: Pulse. Welding. Microcontroller

Abstract. With the development of welding power control technology, pulsed welding technology was becoming more and more popular, for it could control the droplet transfer process by pulse current. In this paper the characteristic of pulsed welding technology was analyzed, and the equipment—welding pulse controller was introduced, which could upgrade the existing welding system to pulsed welding system without too much changes. This paper introduced pulsed MIG welding system and double wire pulsed welding system constructed by welding pulse controller, and the development prospect in the welding field is described.

Introduction

The generation of pulsed welding process was a big leap in the developing history of welding technology in the 60s'. This technology provided a new way to establish welding process, and fundamentally broke the block thought of obtaining stable welding process through constant welding current (voltage). Then the development and application of welding technology moved into a new enormous field.

Since the 1990s', with the updating of welding power control technology, pulsed welding technology got improved gradually and its application range was more extensive. Pulsed MIG/MAG/SAW and other related pulsed welding technology was gradually formed then. Those technology improved the quality and efficiency of welding production greatly, and had great practical value[1].

Characteristics of pulsed welding technology

Wider adjustment range of welding current. With the increasing of alloy element content and strength level, **t**he adjustment range of welding current for the base metal becomes narrow in the welding process. And the production efficiency can be reduced greatly if the welding current is below the lower limit of adjustment range. And weld appearance and welding joint quality can not be good if the welding current is higher than adjustment range limit. Pulsed welding technology can expand the adjustment range of welding current, which is beneficial for production.

Well control heat input and quality of welding joint get improved. In the welding process of high grade steel, the heat input of base metal is limited for its high heat sensitive. If ordinary welding method is adopted, since the selected welding current is small within the adjustment range, the penetration will be shallow and the welding root can have defects such as defective fusion easily. But if pulsed welding method is adopted, the penetration will be deep (penetration depends on the amplitude of pulse current) and the average welding current can be controlled within a lower level. The ductility and toughness of welding joint will be good because the superheated degree of heat-affected zone and weld beam get decreased.

Easy to achieve all position welding. In pulsed welding process, the welding pool is small since the average welding current is decreased. At the same time, the flowing of welding pool is not easy to happen, because the droplet transfer process and the heating of the welding pool is intermittent.

Get refined grains. The stirring of the welding pool by pulse welding current could refine the grain size since the normal growth of grains gets interfered. Common welding defects such as welding porosity and slag inclusion can be decreased at the same time[2].

Pulsed-MIG welding system based on welding pulse controller

The existing traditional welding power source can realize impulse output with the aid of welding pulse controller. The technical solution can be realized by low investment without replacing welding source power in a large scale. And the principle of welding pulse controller is shown in figure 1.

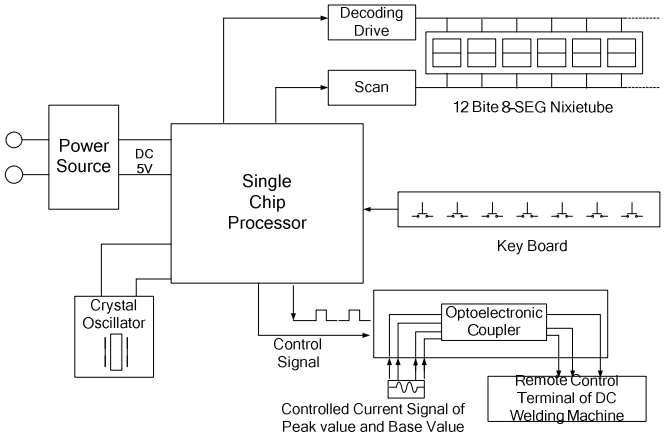

Fig. 1 The principle of welding pulse controller

Under the control of single chip processor, pulse signal is generated, while the frequency and duty cycle can be adjusted according to the requirements of DC pulsed welding. And through the optoelectronic coupler, the given pulsed welding signal is sent to the external remote control terminal of DC welding machine. The output current can be controlled in the form of controlling the given current. And the output peak value and base value can be adjusted independently. In addition, keyboard and nixietube are set on the welding pulse controller to enhance the operation convenience and visualization[3].

Pulsed welding system is composed of pulse welding controller and V300 Lincoln welding machine, shown as figure 2.

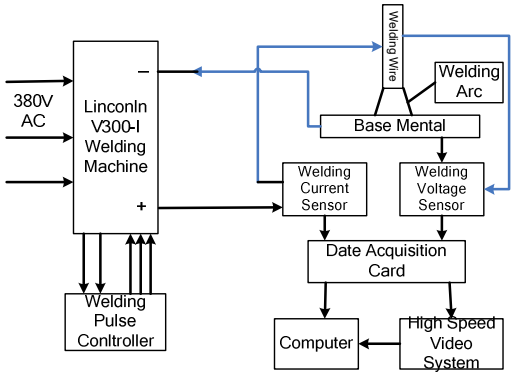

Fig. 2 Pulsed welding system

Welding electric signal waveform within 0.5s of pulsed welding system is shown in figure 3.

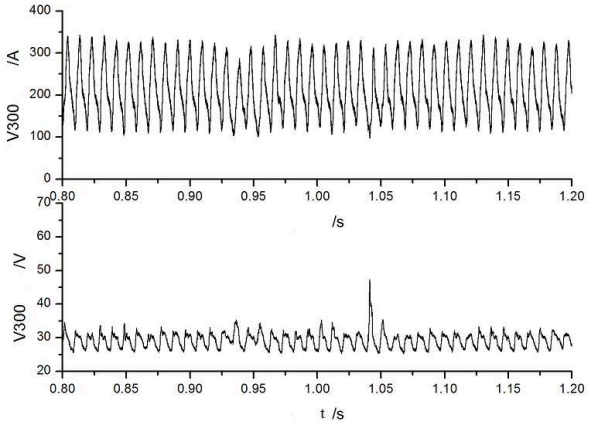

Fig. 3 Welding electric signal waveform of pulsed welding system

The droplet transfer process of one cycle in pulsed welding process is shown in figure 4, and metal transfer mode is one droplet pure pulse.

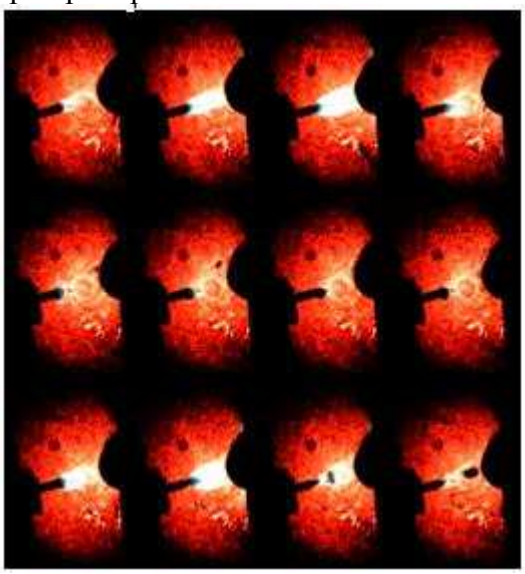

Fig. 4 Droplet transfer process in one cycle(one droplet pure pulse)

Double-wire MIG welding system

Double-wire welding technology developed on the basis of traditional GMAW welding process. In double-wire welding system, two troches are combined in one nozzle, and two completely independent pulse welding sources of the same type are adopted while two conduct tips insulate to each other. Welding parameters of two arcs can be the same or different, the requirement is that the wire feeding must be reliable and the maximum wire feeding speed can reach 15m/min. Two wires melt at the same time, the deposition rate is significantly higher than twice the deposition rate of signal wire welding process, and the welding speed also get increased significantly, which could reach 1m/mim. Double-wire welding system is shown in figure 5, pulse welding current is generated in a push-pull way. In double-wire welding process, in order to obtain welding joint of high quality, the droplet transfer process should be controlled appropriately, or the arc will influence each other, and perturbations will appear[4].

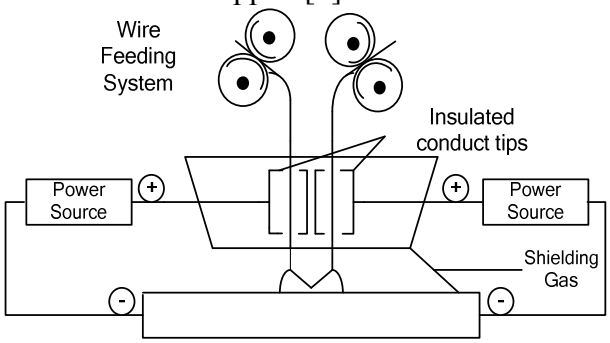

Fig. 5 Double-wire(Tandem)welding system

Double-wire welding system can be formed by adding a V300 Lincoln welding machine and a wire feeding mechanism on the basis of the system shown in figure 2, and the welding electric signal waveform of double-wire pulsed welding process is shown in figure 6.

Two arcs are in push-pull output mode, so the forces between two arcs can be well controlled and the stability of welding process can get ensured.

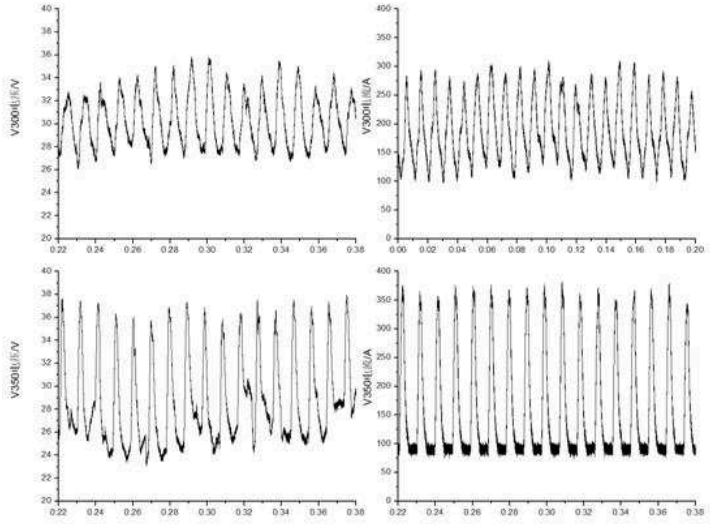

Fig. 6 Welding electric signal waveform of double-wire pulsed welding process

High speed video pictures of double-wire welding process is shown in figure 7, it's obvious that one arc is at peak value state and the other arc in at base value state.

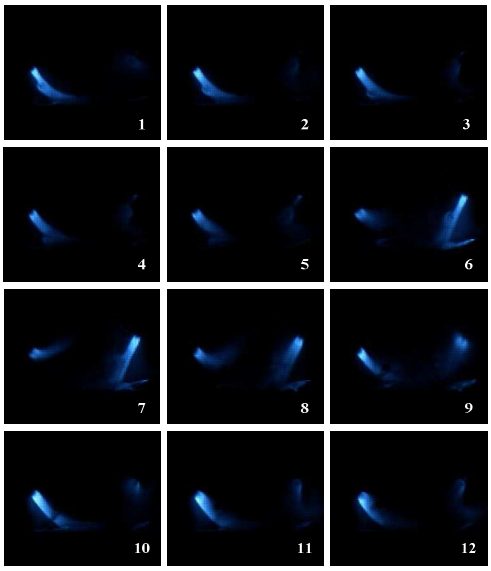

Fig. 7 High speed video pictures of double-wire welding process

Application of pulsed welding technology

In the welding production of X80 steel pip, in order to increase the welding efficiency, the welding current in SAW must be increased, which will lead to grain growth and related performance degradation. While in pulsed SAW process, the property of welding joint is improved since the heating mode is changed and grain size of welding beam is refined by electromagnetic vibration.

Based on DC1500 Lincoln welding power source and welding pulse controller, pulsed SAW system is constituted. Through the analysis of comparative experiment, the grain of welding joint with pulse current is smaller. And it shows that pulsed SAW technology has a good application prospects and certain advantages in welded pipe production.

Through comparing the welding seam under pulsed welding process and non-pulsed welding process at the same current level, it can be seen that the grain of pro-eutectoid ferrite is coarse in non-pulsed welding process. As X80 is fine grain steel, such coarse grains could affect its properties seriously. The appearance of coarse grain means that in grain growth process, the superheated degree and dwell time in the over-heating stage in non-pulsed welding process are much higher. And it proves that the heating mode between pulsed and non-pulsed welding process is different, and pulsed SAW welding process has advantage in grain refinement than ordinary SAW welding process[5].

Conclusion

1) Pulsed-MIG welding system and double wire MIG welding system were constructed with welding pulse controller, so the exiting welding system got upgrade without too much change.

2) In the experiment, the metal transfer process and corresponding wave-form of welding current, arc voltage were recorded which showed the welding pulse controller can realized pulsed output.

3) The welding pulse controller has great application value for production.

Dr. Research direction: Monitoring detection and vehicle safety

Keywords: Abnormal sound on-vehicle, Fault diagnosis, Warning system, ECU

Abstract. Automotive abnormal sound is an important manifestation of the automotive system components early malfunction. It can effectively improve safety and reliability of the vehicle system by characteristics extraction of abnormal vehicle sound and prediction of the development trend of fault. What's more, it can solve the problem that ECU can't identify tire failure and other problems. As a result, it will reduce the number of traffic accidents, protect human safety and property.

Introduction

Car abnormal noise is the most obvious manifestation of the early fault of vehicle. For example, the abnormal noise of " zhi, zhi, zhi" when braking indicates that the wear of automotive brake friction Lining is beyond the limit; If you hear a harsh abnormal noise of "qiu, qiu, qiu" that comes from the engine, it indicates the excessive wear or slack of the v-belt; If you hear abnormal noise of metal collision that comes from the tire's internal, it is probably caused by broken damper and bearing [1-2]. Automotive abnormal sound will not affect the car's driving immediately, but it will seriously affect the ride comfort, causing the passenger irritability, decreasing the attention of the driver or other adverse symptoms. Given no timely maintain, it will cause other automotive fault. The faults that can be indicated by abnormal sound include engine noise, transmission noise, braking noise and tire abnormal sound. For the early stage of abnormal noise, it is mainly judged by experienced garage men or drivers. But for the widespread use of cars, drivers are increasingly diversified and young, and most of them don't have ability of correct judgment. So developing a method for fault diagnosis through automatic abnormal noises is more and more urgent.

At present, research for car fault diagnosis system is limited to typical faults or single fault mostly .Most fault diagnosis systems use the contact vibration test for on-line fault monitoring, or use the method for separating parts for Offline detection [3]. But the fault in car when moving is complicated and coupling, so the fault signal is also coupling, and the components of signal are complicated, current method of contact vibration can't detect assembly fault source and early stage of fault completely, and it's also difficult to test car's assembly operation state and fault accurately by the method of traditional time domain or frequency domain analysis, especially the incipient fault after mechanical system's long wear [4].How to develop a fault diagnosis technology of vehicle system that is efficient, accurate and multi-source information integrated has been the concern of people and a new research focus.

Engine noise

There are multiple causes that can lead to engine noise. The belt howling relatively harsh, it is generally caused by belt slippage. If the external metal parts emit dry friction sound when the engine is running, it suggests that the generator bearing has been damaged.

Ming-Long Zhou, from Anhui University of Engineering, has proposed an automobile engine fault diagnosis method of genetic algorithm, wavelet and neural network [5]. Wen-Ping Yang, from Northwestern Polytechnical University has studied the nonlinear characteristics of automotive

engine systems by solving the system of the largest Lyapunov exponent to diagnosis and monitors the engine fault [6]. Yu-Xiu Xu from Tianjin Polytechnic University has studied that using support vector machine method to realize the diagnosis and identification of engine failure in the case of car engine without disassembly [7]. Huan Li, from Zhoukou Normal University, has made a car engine sensor fault detection method based on fuzzy energy self-learning [8].

Currently, there are many ways to study the automobile engine fault diagnosis, mainly focus on the engine compartment offline measurement and static in on-line measurement. The methods are mainly neural networks supporting vector machines, or the application engine fault identification of abnormal sound signals. They are feasible, however, these diagnostic methods are studied and validated based the known faults, it has not yet had a way to diagnose the online fault of engine. Meanwhile, there is no way to separate the abnormal sound of the engine from the vehicle information system in the whole different sound information.

Gearbox Abnormal Sound

When driving, if all the crosspieces, except the direct crosspiece, make some abnormal noise, it indicates that the noise is from the second front axle of the transmission; if there is a "rustling" sound in the gearbox when driving, and when depressing the clutch, it disappears, this is caused by the gearbox bearing or gear wears, bearing spots. Nissan CVT, Volkswagen DSG gearbox problem still exist, Fault diagnosis can provide more protection for it.

Lu Jianwei etc, from College of Mechanical and Automotive Engineering of Hefei University of Technology, analyzed the transmission gear abnormal sound failure from the perspective of nonlinear dynamics [9]. Wu Xiaobing, from Beijing Institute of Technology, found the optimal parameters for each failure through gray cognate analysis combined with rough set theory [10]. Tongji University ’Wan De’an etc use the time domain synchronous averaging method in auto gearbox fault diagnosis system of the fault to diagnose [11]. Liu Ze etc. in Changchun University of Technology use improved ID3 algorithm to the automobile gearbox fault diagnosis [12].

Vibration detection and diagnosis is currently the most widely method for Gearbox fault diagnosis, as abnormal sound information is easily mixed with ambient noise, so abnormal sound detection and diagnosis has not been well developed and applied. With the development of technology, the techniques of dealing with noise and the ability of hardware and software is also rising, online fault diagnosis method for different sound will be the main developing direction of the gearbox fault diagnosis.

Brake abnormal sound

The abnormal noise, made by the automobiles when breaking, is probably arose by these factors, such as the improper use of the material or big distortion of Brake Disc or the hardness, the Porosity, Friction Characteristics and squeezing properties of Brake Friction Lining are unqualified. If there was no timely treatment of these faults, especially under high speed driving, the drivers may have dangerous.

LI Rong from Shantou University designed the information extraction and Data Processing for the Monitoring System, by using the technology and theory of sensor array and Multi-sensor Data Fusion [13]. Through quality monitoring system of DSP brake disc’s internal defect, by using computer control technology, DSP technology and Sensing Technology to collect the key characteristic variable, based on Bayes’s stepwise discriminant analysis, Zhou Guanxiong, from zhejiang university, established the discriminant function of diagnosing the Brake Disc’s Internal Defect[14].

The fault diagnosis method of Brake System’s running state is not that popular at present. The existing diagnosis method is almost based on the detection according to brake disc itself. There is no On-line detection of the abnormal noise of the brake disc at present.

Tire abnormal sound

The noise of tire must be rhythmic, and the frequency rises with the driving speed. If the noise is like “PA PA”, it is probably caused by big distortion, bulging deformation, wear or Shortage of tire air pressure; If the noise is like “DA DA”, it is probably caused by the little stones in tire tread; if the noise is like “HU HU”, and car body shakes intensely even runs deviation, it is probably caused by tire burst.

At present Tire Pressure Monitoring System is used during driving. It measures the internal pressure and temperature by the detecting sensor installed in the tire. These measured values are shown on the Panel directly. If the values exceed the safety range, it will send out warning signal. Fangwei and some of his colleagues, from Wuhan Digital Engineering Research Institute, have established a Distributed Condition Monitoring and Fault Diagnosis System for tire, by using sensor technology, microelectronics, embedded technology and Radio Frequency Communication Technology[15]. Wang Chengrui and his colleagues, from Dalian University of Technology, have designed a direct Condition Monitoring and Fault Diagnosis Active Forewarning System for tire, by using ZigBee technology to forewarn the tire fault actively [16].

The existing Diagnosis Methods for tire fault are all based on the internal pressure and temperature measured by sensors. But even when these values are normal, if the abnormal noise made by foreign body in the tire or the tires’ not being fixed well are not judged correctly by the drivers, the continuing driving may cause problems or even traffic accidents. Temporarily there isn’t an On-line detection of the abnormal noise of the foreign body in the tire.

Automotive ECU self-diagnostic function

ECU with self-diagnostic and protection functions ，When a system failure, it automatically records the fault code through the use of protective measures RAM and read from the alternative procedures inherent in the program to maintain the engine running . While these faults are displayed on the instrument panel and keep immortal, make the driver to detect problems.

Recently, ECU applies not only in engines, but also in anti-lock brake system, 4 wheel drive system, Auto Manual Transmission and active suspension system and so on.

Conclusion

Fault diagnosis method of the part of automotive is mostly applied in off-line fault detection, and it has a higher requirement in Computer Aided inspection and diagnosis system, so it can’t be used as the early fault diagnosis in automobiles which are traveling. Through the above analysis, abnormal noise can describe the early fault diagnosis in automobiles which are traveling, and realize real time monitoring and early-warning. The existing fault diagnosis technology has some problems, such as:

1) Can’t do analysis of the whole automobile failure diagnosis.
2) Have not a way to do early fault diagnosis.
3) The engine diagnosis method is researched based on all known failure.
4) The automobile brake system diagnosis method is based on brake pad.
5) The present tire fault diagnosis method is based on tire pressure and temperature diagnosis.

In conclusion, the comprehensive fault diagnosis method based on abnormal noise can diagnose and warn the early fault diagnosis and abnormal noise of each part, and it offers the field of automobile safety a practical way. The method also can improve the driving stability and security and achieve better economy benefit and social benefit by monitoring the development trend for automobile early fault. It fills a gap in automobile abnormal noise diagnosis field, and has a immeasurable value and meaning in automobile reliability research.

Keywords: Construction machinery; Hydraulic cylinder; Disassembly and assembly equipment; hydraulic system;

Abstract. Construction machinery hydraulic cylinder is usually discarded after service cycle. The residual value of discarded products can be recycled greatly by remanufacturing. Disassembly and assembly is the key process in hydraulic cylinder remanufacturing. The construction machinery hydraulic cylinder disassembly and assembly equipment is developed. Hydraulic power is adopted in this equipment. The clamping, positioning of cylinder tube is realized by hydraulic clamping mechanism automatically. The piston component pulling out or into cylinder tube is realized by hydraulic working mechanism automatically. This equipment has been applied successfully in the project of "key technology and equipment for construction machinery parts remanufacturing" in a research institute. The results indicate that the application of this equipment will not only increase the automaticity and efficiency remarkably, but also reduce the damage to hydraulic cylinder key part greatly.

Introduction

After serve cycle, the volume efficiency and working pressure of construction machinery hydraulic cylinder will decline remarkably [1]- [2]. There is little damage occurs in key parts, such as piston rod, piston and cylinder tube dismantled from discarded construction machinery hydraulic cylinder. The failure parts of discarded hydraulic cylinder tend to occur only in sealing elements [2]. The performance of discarded hydraulic cylinder will improve remarkably, even measure up to new products by disassembling, cleaning, replacing sealing elements and reassembling. Thus, the residual value of discarded construction machinery hydraulic cylinder can be recycled greatly [3].

Cylinder rod component must be pulled out from cylinder tube in disassembling process. This process is very difficult because of the serious damage, deformation, tearing and aging in sealing elements of piston and guide sleeve [4]. Mounting piston rod component in cylinder tube is also a difficult process in assembling hydraulic cylinder. Unnecessary damage to key parts usually occurs during assembling and disassembling process without specialized equipment [4]. The disassembly and assembly equipment for construction machinery hydraulic cylinder is developed in this paper.

Mechanism Designing

The functions of disassembly and assembly equipment for construction machinery hydraulic cylinder are described as follow. The clamping, positioning of cylinder tube is realized by hydraulic clamping mechanism automatically during assembling and disassembling process. After cylinder head fixing parts (e.g. flange bolt or clasp) are dismounted, piston rod component and guide sleeve of disassembled hydraulic cylinder can be pulled out from cylinder tube by hydraulic device in disassembling process. Piston rod component and guide sleeve of assembled hydraulic cylinder can be mounted in cylinder tube by hydraulic device in assembling process.

Structure of Equipment

The disassembly and assembly equipment for construction machinery hydraulic cylinder is shown in Fig 1. The main components of the equipment installed on the cylinder clamping base frame 11 and

the slide rail base 9, these two base frames are connected each other by bolts. The hydraulic cylinder to be repaired can be clamped on the cylinder clamping base frame 11. Two V blocks of cylinder tube bracket are installed on two screw rods separately, so the height of V block is adjustable. The cylinder tube can be lifted to the appropriate height so as to clamping. There are two sets clamping device, which is composed of positioning V block 10 and clamping V block 3. Positioning V block 10 is drove by screw rod and clamping V block is drove by Hydraulic cylinder. Adjusting the position of V block 10 by screw rod, the position of the cylinder tube axis can be ensured on the medium position, in order to connect the piston rod mounting hole of hydraulic cylinder to be repaired to connecting flange 8. If the hydraulic cylinder to be repaired has a mounting hole on the rear of cylinder tube, the mounting hole on the rear of cylinder tube can be connected to mounting hole of the bracket 1 directly. Adjusting all these devices and placing the cylinder tube on V block 2, then the cylinder tube can be positioned and clamped by hydraulic devices.

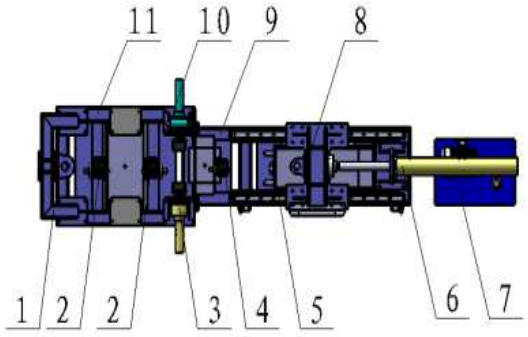

Fig.1: Disassembling/assembling equipment for hydraulic cylinder

The working mechanism of this equipment is composed of linear guide rail 5, fluid cylinder 6 and slider block bracket 8. Linear guide rail 5 mounted on guide rail base frame 9. The slider block bracket 8 is drove by hydraulic cylinder 6 and reciprocate on linear guide rail 5. The piston component of hydraulic cylinder to be repaired can be pulled out o inserted into cylinder tube by retracting and stretching of hydraulic cylinder 6. The V block with rubber sheet mounted on piston rod carrier 4 can move up and down. During disassembling process, piston rod will fall onto the V block after pull out of cylinder tube, so as to avoid the damage to piston rod. During assembling process, the function of the V block is vertical positioning for piston rod. 7 shown in this figure is hydraulic power unit.

Working principle

Disassembling Process of Hydraulic Cylinder

1) Adjusting the position of V block on cylinder tube carrier 2, screw rod centering device 10 and piston rod carrier 4 according to the diameter of cylinder tube to be disassembled. Attention: the height of V block on cylinder tube carrier should lower 0 - 5mm than theoretical height and the height of V block on piston rod carrier shouldn't higher than theoretical height. Then place the cylinder tube on V block 2;

2) Stretching the piston rod of clamping device hydraulic cylinder 3, clamping the cylinder tube of hydraulic cylinder to be disassembled by a pair V blocks on clamping hydraulic cylinder 3 and screw rod centering device 10;

3) Dismounting and removing fasteners on hydraulic cylinder head to be disassembled;

4) Starting working device hydraulic cylinder 6, moving slider block bracket 8 to the appropriate position, mounting piston rod mounting hole of hydraulic cylinder to be disassembled on connecting flange of slider block bracket 8;

5) Retracting piston rod of working device hydraulic cylinder, the cylinder lid, guide sleeve and piston component will separate from cylinder tube;

6) Retracting piston rod of clamping device hydraulic cylinder and unclamping clamping device, removing cylinder tube and piston rod component of hydraulic cylinder to be disassembled from this equipment[3-4].

Assembling Process of Hydraulic Cylinder

1) Adjusting the position of V block on cylinder tube carrier 2, screw rod centering device 10 and piston rod carrier 4 according to the diameter of cylinder tube to be disassembled. Attention: the height of V block on cylinder tube carrier should lower 0-5mm than theoretical height and the height

of V block on piston rod carrier should lower 0-1mm than theoretical height. Then place the cylinder tube on V block 2;

2) Stretching the piston rod of clamping device hydraulic cylinder 3, clamping the cylinder tube of hydraulic cylinder to be assembled by a pair V blocks on clamping hydraulic cylinder 3 and screw rod centering device 10;

3) Fitting the cylinder lid, guide sleeve component on piston rod and fixing piston on piston rod;

4) Starting working device hydraulic cylinder 6, moving slider block bracket 8 to the appropriate position, mounting piston rod mounting hole of hydraulic cylinder to be assembled on connecting flange of slider block bracket 8;

5) Stretching piston rod of working device hydraulic cylinder, the piston component to be assembled will be inserted into the cylinder tube;

6) Fixing guide sleeve and cylinder lid on hydraulic cylinder head to be assembled;

7) Retracting piston rod of clamping device hydraulic cylinder and unclamping clamping device, removing hydraulic cylinder disassembled from this equipment.

Main Design Parameter

In order to meet the requirement of most construction machinery hydraulic cylinder disassembling/assembling process, according to the mainstream hydraulic cylinder used in loader and grader, which have large quantity and are widely used the main parameter of the construction machinery hydraulic cylinder disassembling/assembling equipment are designing as follows:

Table 1: Main design parameter

item		parameter
hydraulic cylinder to be repaired	min. outside diameter of cylinder tube	90mm
	max. outside diameter of cylinder tube	300mm
	max. stroke	1800mm
clamping device	max. clamp force	2.5t
	stroke	160mm
working device	max. pulling force	0.9t
	max. thrust force	1.8t
	stroke	950mm
rhythm of production	clamping	5s
	pulling out piston component	≤25s
	inserting piston component	≤25s

Designing of Hydraulic System

The hydraulic principle diagram for this equipment is shown in Fig 2: there are two actuator units and one power unit in this hydraulic system, which are working hydraulic cylinder 15, clamping hydraulic cylinder 21 and hydraulic pump 6.

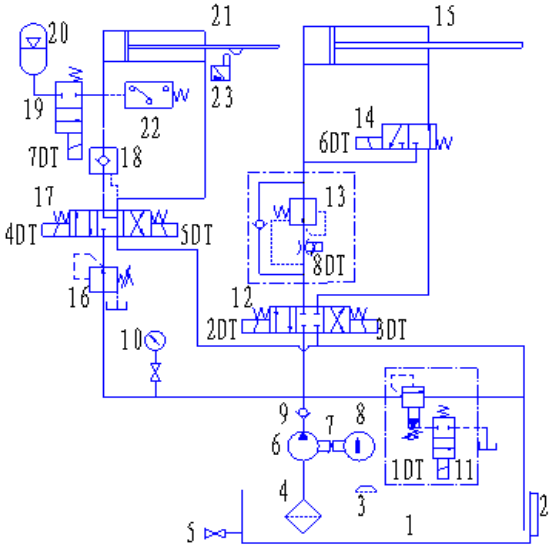

Fig. 2: Hydraulic principle diagram

Clamp Cylinder Tube of Hydraulic Cylinder to be Disassembled/Assembled

Solenoid 7DT switch on, after 0.5 second, solenoid 4DT switch on, power system supply oil for rodless cavity of clamping cylinder 21 and accumulator 20, the piston rod of 21 stretches out and clamps the cylinder tube. While the clamping force increasing to the force setup prior, pressure relay 22 switch off the

solenoid 4DT. The pressure in rodless cavity of clamping cylinder 21 will sustain by accumulator 20 and one-way valve 18, so that the cylinder tube remain clamping status while the piston component is being pull out or inserted into cylinder tube. The clamping force is setup by pressure relay 22. The maxima clamping force is setup by reducer valve 16, so as to avoid damage to cylinder tube while there is fault in pressure relay.

Slider Block Bracket Adjusting and Positioning

Adjusting and positioning slider block bracket is realized by stretching and retracting of piston rod of working hydraulic cylinder 15.Switching on Solenoid 2DT, the piston rod of working hydraulic cylinder will stretch. Switching on Solenoid 3DT, the piston rod of working hydraulic cylinder will retract. Taking work condition and efficiency into consideration, if the piston rod must stretch a long distance, the solenoid 6DT switch on, thus the differential connection is realized.

Pulling Out and Inserting of Piston Modula

Solenoid 2 switching on, working cylinder 15 will stretch and hydraulic cylinder piston rod component will assembly in cylinder tube. Solenoid 3 switching on, working cylinder 15 will retract and hydraulic cylinder piston rod component will pull out of cylinder tube. Valve 13 is an electromagnet proportionality speed regulating valve. While the hydraulic cylinder piston approaching the cylinder head, the speed should reduce by valve 13 for safety. After this stage, the speed may increase to normal level. The speed is controlled by electromagnet proportionality speed regulating valve and adapt remote operation mode, so the flexibility and convenience is improved remarkably.

Unclamping Cylinder Tube of Hydraulic Cylinder to be Disassembled/Assembled

Solenoid 5DT switching on, piston rod of clamping cylinder 21 retract. Solenoid 7DT switching off to avoid unnecessary release of accumulator pressure energy. While approaching end, position switch SQ1 switch off solenoid 5DT.

Off-loading and Overload Protection

The maximal working pressure of this system is setup by electromagnetic relief valve 11, which used as overload protection and off-loading. While the work status of electromagnetic valve 17 and 12 is neutral (i.e. 2DT, 3DT, 4DT, 5DT switch off), this system is on off-loading status by valve 11. If the equipment is out of service for a long time, pressure energy stored in accumulator can be released by switching on solenoid 5.

Applicationg

This equipment has been applied successfully in the project of "key technology and equipment for construction machinery parts remanufacturing" in a research institute. The steering hydraulic cylinder of ZL50 loader is being disassembled on this equipment as shown in fig.3. Disassembling this hydraulic cylinder require 3 minutes and assembling require 5 minutes. The results indicate that the application of this equipment will not only increase the automaticity and efficiency remarkably, but also reduce the damage to hydraulic cylinder key part greatly.

Fig.3:Application of This Equipment

Keywords: Worm geared transmission, Static stiffness, Sensitivity analysis

Abstract. The worm geared transmission chain is widely employed in rotary feeding table of machine tools. This article proposes a static stiffness model and conducts sensitivity analysis of the transmission chain. Firstly, a unified static stiffness model is established, considering meshing stiffness, torsional stiffness and pre-load related axial stiffness of worm shaft. Then sensitivity with respect to individual stiffness element is derived based on partially differentiating method. Simulation results show that the closer to the end gear pair or shaft is, the more sensitive meshing stiffness or torsional stiffness is.

Introduction

As a key component of multi-axis machine tool, the performance of rotary feeding table has an important influence on that of the whole machine tool.The dynamic stiffness depends on static stiffness, inertia or mass of components, damping etc [1,2]. Feng investigated the axial stiffness of rotary table by proposing a new type of rotary table with a comprehensive performance of high stiffness and low cost, then a multi-objectives optimum design was conducted [3]. Huang investigated the dynamic characteristics of the axial and circumferential directions of a large and heavy NC rotary table [4]. The positioning accuracy of the rotary feed system without load mainly depends on the geometric error (e.g., free play between meshing teeth); however, when torque load is applied, rotating angular deviation from the desired mainly comes from the stiffness of the transmission chain. However, few researches could have been found [5].

Figure 1 shows a typical transmission chain employed in rotary table for rotary feeding, where there're both cylindrical gear pairs and worm gear pair.

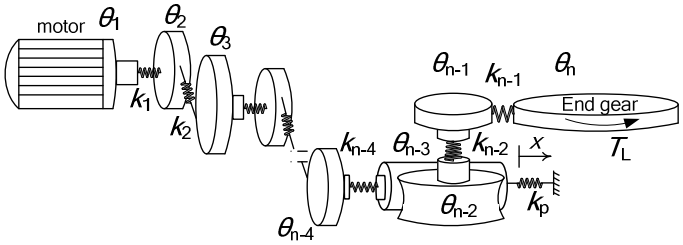

Figure 1 Schematic of general worm geared transmission chain

As shown in the figure, the rotating angles from the input motor to the end gear of the transmission chain are denoted as $\theta_1 \ldots \theta_n$, respectively. Similarly, the stiffness of each elastic element is represented by $k_1 \ldots k_{n-1}$, respectively, where n=odd means the torsional stiffness of shaft and n=even stands for the meshing stiffness of gear teeth. In addition, k_p stands for the axial stiffness of worm shaft, mainly depending on the supporting bearings on both ends of worm shaft.

Based on static equilibrium equations, the torsional stiffness of the chain could be obtained,

$$k_s = k_{n-1} r_{bn}^2 - k_{n-1} r_{b(n-1)} r_{bn} A_{(n-1)n} \tag{1}$$

where A_{12}=0, and $A_{i(i+1)}$ ($2 \leqslant i \leqslant n-4$) takes following form

$$A_{i(i+1)}=\begin{cases}\dfrac{k_i}{k_i+r_{bi}^2k_{(i-1)}-r_{b(i-1)}r_{bi}k_{(i-1)}A_{(i-1)i}} & i=odd\\ \dfrac{k_ir_{bi}r_{b(i+1)}}{k_{(i-1)}+r_{bi}^2k_i-k_{(i-1)}A_{(i-1)i}} & i=even\end{cases} \tag{2}$$

According to the Eq.(1) &continuous differentiating method, the analytical sensitivity models for each component's stiffness are derived as

$$\frac{\partial k_s}{\partial k_i}=\begin{cases}\dfrac{\tilde{r}_{bn-2}\overline{r}_{bn-3}}{\overline{r}_{bn-2}\tilde{r}_{bn-3}}(A_{i(i+1)}-1)^2\prod_{j=i+1}^{n-1}A^2{}_{j(j+1)} & i=odd\\ \dfrac{\tilde{r}_{bn-2}\overline{r}_{bn-3}}{\overline{r}_{bn-2}\tilde{r}_{bn-3}}(r_{bi}A_{i(i+1)}-r_{bi+1})^2\prod_{j=i+1}^{n-1}A^2{}_{j(j+1)} & i=even\end{cases} \tag{3}$$

Simulation results discussions. The schematic of a transmission chain with worm gear pair is shown in figure 2. Obviously, the index n=7 in this example, and the angle of end gear is denoted as θ_w.

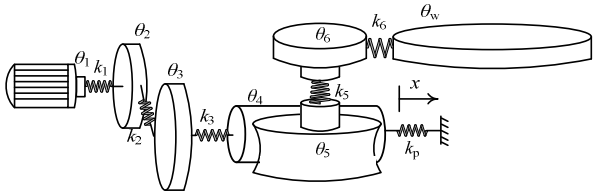

Figure 2 Transmission chain used in simulation

To verify the proposed static stiffness model, a comparison between the result obtained from finite element method and these from the analytical model is made. The parameters of the chain are shown in Table 1.

Table 1 Parameters of the transmission

	Z_2	Z_3	Z_4	Z_5	Z_6	Z_w
teeth number	21	67	1	31	17	71
module (mm)	4		4		5	
width (mm)	56				70	
pressure angle	20°					
r_1 (mm)	20	r_3 (mm)	15	r_5 (mm)		20
L_1 (mm)	70	L_3 (mm)	80	L_5 (mm)		75

The results from both FEM and analytical model are given in Table 2.

Table 2 Comparison between FEM and analytical model

(mm)	Torsional static stiffness (Nm/rad)		(N/m)	Torsional static stiffness (Nm/rad)	
r_5	FEM	Analytical model	k_p	FEM	Analytical model
30	2.3801×10^6	2.4002×10^6	1.4×10^8	2.0213×10^6	2.0392×10^6
25	2.1277×10^6	2.1708×10^6	1.2×10^8	1.8768×10^6	1.8901×10^6
20	1.7119×10^6	1.7146×10^6	1.0×10^8	1.6819×10^6	1.7094×10^6
15	9.6614×10^5	9.6918×10^5	0.80×10^8	1.4885×10^6	1.5038×10^6

As could be seen from the table, there're little differences between the results from two models and the stiffness obtained from finite element model is a little lower than those from the analytical model. These differences may be introduced by the non-rigid worm shaft and gear bodies.

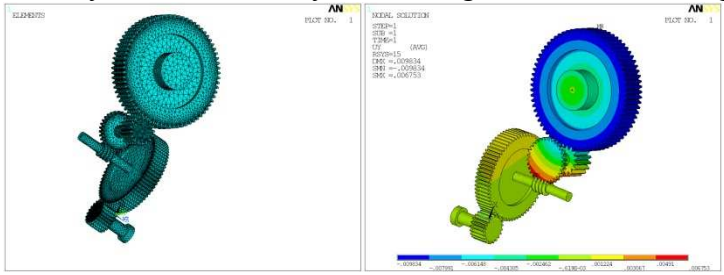

Figure 3 FEM model

Sensitivity to stiffness component. Two methods are employed in sensitivity analysis: analytical method presented in above sections and the difference method. The simulation results from two methods are shown in the following figure.

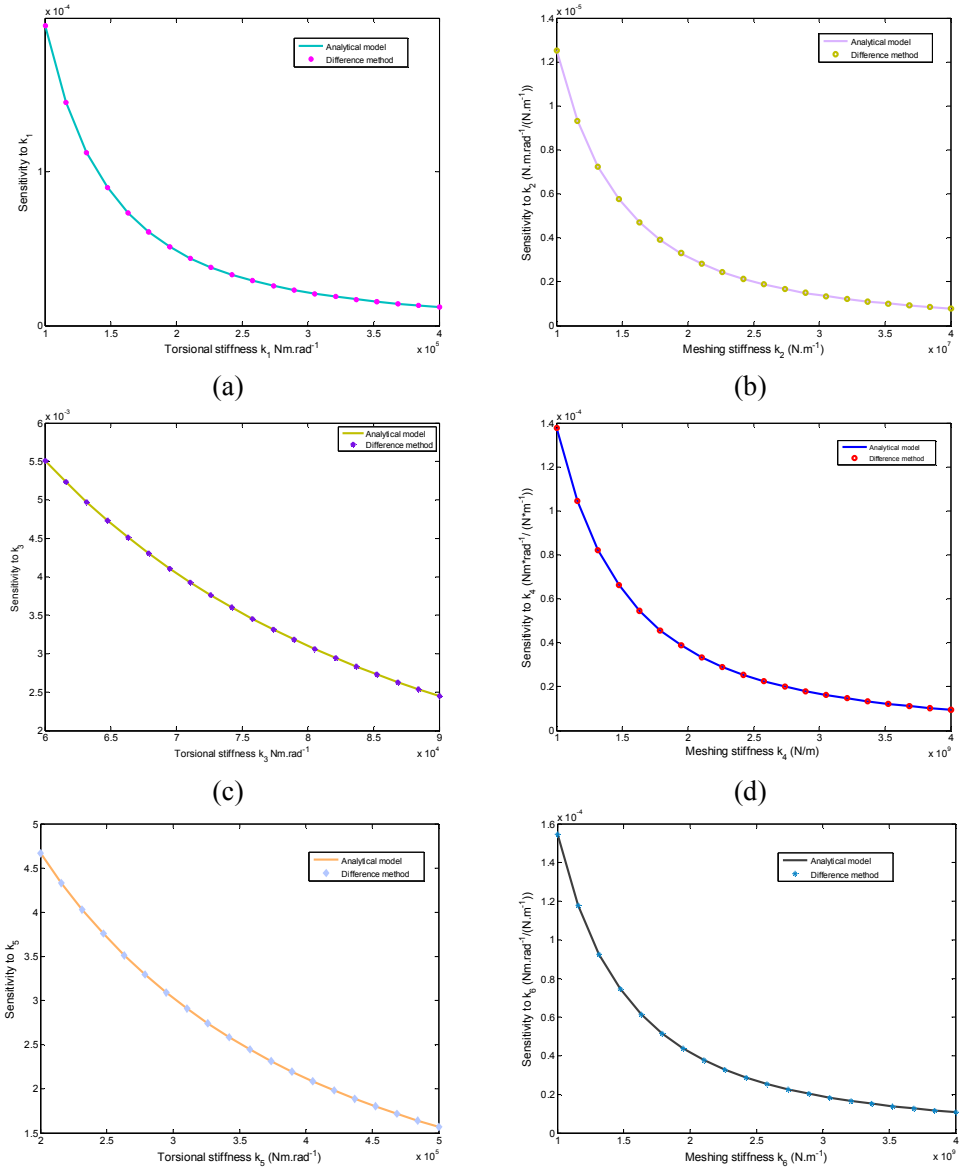

Figure 4 Verification of analytical sensitivity model

Compared to the meshing stiffness of gear pairs, the torsional stiffness of shaft is more sensitive to the static stiffness of the whole transmission chain; the closer to the end gear pair or shaft is, the more sensitive meshing stiffness or torsional stiffness is. And in this case, the axial stiffness of bearing supporting worm shaft is relatively lower than others except k_5, as could be seen from Fig.4.

Keywords: Theoretical model, High speed milling, Surface roughness, Cutting parameters.

Abstract. High speed milling is a newly developed advanced manufacturing technology. Surface integrity is an important object of machined parts. Surface roughness is mostly used to evaluate to the surface integrity. A theoretical surface roughness model for high face milling was established. The influence of cutting parameters on the surface roughness is analyzed. The surface roughness decreases when the cutter radius increases, total number of tooth and rotation angular speed, while it increases with the feeding velocity. The high speed face milling can get a smooth surface and it can replace the grinding with higher efficiency.

Introduction

High speed machining is a newly developed advanced manufacturing, and it improves the manufacturing efficiency [1], lowers the manufacturing cost, lowers the cutting energy. The high surface integrity of workpiece can be obtained after high speed machining [2]. High speed machining has been widely used in the world due to the great many advantages. Surface integrity is a most obvious character of high speed machining. To obtain the higher quality of surface roughness is a challenging work for high speed machining.

Ozcelik[3] once developed a statistical model for surface roughness estimation in a high-speed flat end milling process including spindle speed, feed rate, depth of cut, and step over, Ozcelik found the order of depth of cut, step over, spindle speed and feed rate on the surface roughness. Lee [4] established a surface roughness model considering the cutting tool deflection in end milling. Colak [5] have predicted the surface roughness with the gene expression programming. Dweiri [6] optimized the cutting parameters with adaptive neuro fuzzy inference system (ANFIS) in down milling of Alumic-97, and concluded that the better surface roughness can be obtained with four flutes.

The paper aims at the goal of modeling the surface roughness in high speed face milling. The influence of cutter radius, total number of tooth, feeding velocity and rotation angular velocity on surface roughness were analyzed.

Modeling the surface roughness

The trajectory of cutting edge is shown in Eq. (1).

$$\begin{cases} ox_i = vt + r_c \cos(\omega t + \alpha - \dfrac{2\pi i}{N}) \\ oy_i = r_c \sin(\omega t + \alpha - \dfrac{2\pi i}{N}) \end{cases} \tag{1}$$

where v is the feeding velocity in the ox direction, r_c is the radius of face milling cutter, ω is the rotation speed of face milling cutter, α is the initial angle of the first cutter in the face milling cutter, i is the No. of the tooth, N is the total number of tooth.

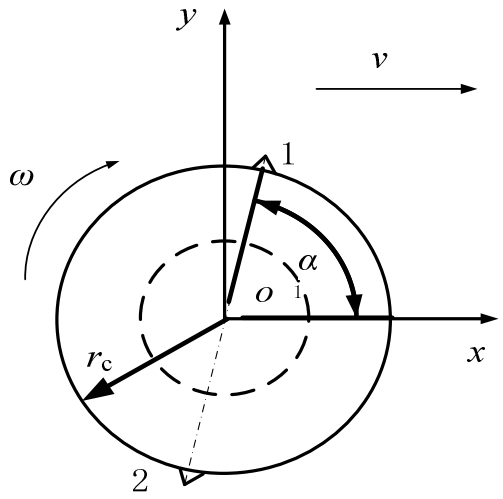

Fig. 1 Sketch of face milling cutter

Fig. 2 shows the scallop height h after the face milling cutter passes. As shown in fig. 2, h can represent the surface roughness in face end milling. To obtain the value of h is a challenging problem to optimize the cutting parameters.

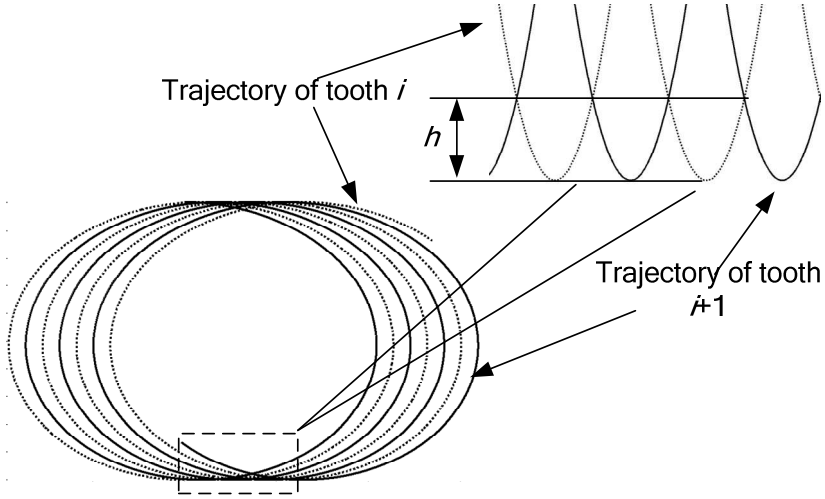

Fig. 2 Diagram of scallop height in high speed face milling

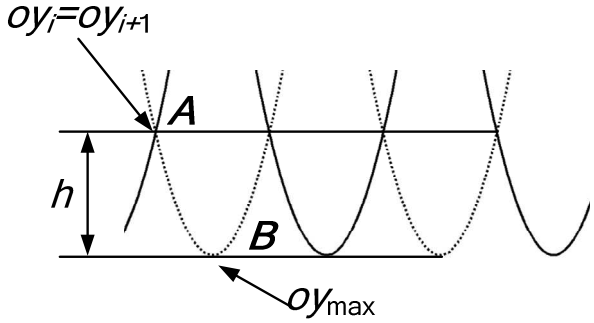

Fig. 3 Diagram of scallop height in high speed face milling

$$h = \left| oy_{i+1} - oy_{\max} \right| \tag{2}$$

$oy_{\max}$ is the maximum trajectory in the oy direction, oy_1 is the interaction point of trajectory of the tooth i and i+1 as shown in Fig. 3. The $i$tooth reaches point A when the milling time go to t, and the (i+1)th will pass point A later. in the feed direction, the position ox can be calculated with Eq. (3).

$$ox_i = ox_{i+1} \tag{3}$$

then an equation of time t can be got with Eq. (4).

$$f(t) = r_c \sin\left(\omega(t + \Delta t) + \alpha - \frac{2\pi(i+1)}{N} \right) - r_c \sin\left(\omega t + \alpha - \frac{2\pi i}{N} \right) - f_z \tag{4}$$

where f_z is the feed per tooth, Δt is the increment time between ith and (i+1)th, it can be calculated with Eq. (5).

$$\Delta t = \frac{\omega}{2\pi N} \tag{5}$$

The Eq. (5) is a complex and difficult to solve, Eq. (6) gives a Newton-Rapson method to solve the milling time.

$$t_{i+1} = t_i - \frac{f(t)}{f'(t)} \tag{6}$$

Results and discussion

Table 1 shows the cutting conditions in detail. Fig. 4 shows the surface roughness variation with the parameters shown in Eq. (1). It can be seen that the surface roughness decreases with the cutter radius, total number of tooth and rotation angular speed decreasing, while it increases when the feeding velocity increases. The surface roughness even can be smaller than 0.01 μm. It can be seen that the high speed face milling has a promising future to replace the grinding.

Table1 Cutting conditions

Total number of tooth	Feeding velocity (m/min)	Rotation angular speed(rad/s)	Radius of cutter(mm)
2-4	0.1-0.3	52.4-261.8	40-65

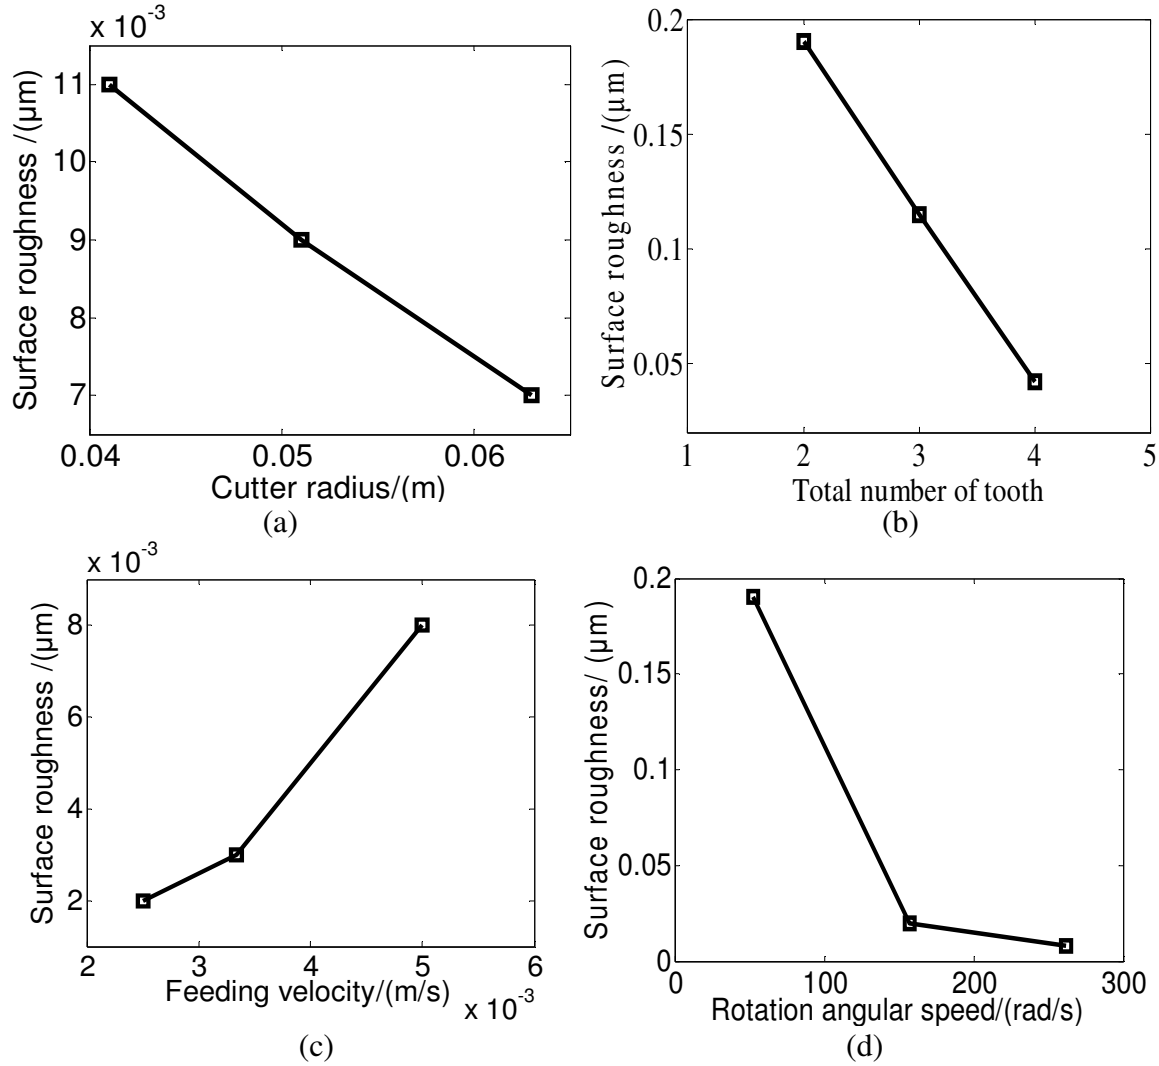

Fig. 4 Surface roughness variation with cutting parameters

Conclusions

Surface roughness is an important parameter of surface quality. The milling parameters have great influences on the surface roughness in high speed face milling. A theoretical model is established to investigate on the surface roughness in high speed face milling. The model can be used to optimize the surface roughness in the expected range. The following conclusions can be drawn:

1) The surface roughness decreases with the cutter radius increasing.
2) The surface roughness decreases with the total number of tooth increasing.
3) The surface roughness increases with the feeding velocity increasing.
4) The surface roughness decreases with the rotation angular speed increasing.

An Analysis of Electric Inertia Simulation Method On The Test Platform of Electric Bicycle Brake Force

Zhaoxu Yu[1,a], Hongbin Yu[2,b]

[1,2]School of Mechanical Engineering, Tianjin Polytechnic University, Tianjin, China, 300387

[a]836665408@qq.com, [b]hongbinyu@aliyun.com

Keywords: Electric bicycle brake force; Electric inertia simulation; Test platform

Abstract. This paper analyzes the electric inertia simulation method deeply. By analyzing the brake torgue in the braking process, this paper makes a conclusion about the relationship between the moter's torgue in the braking process and the simulation of inertia. The test uses the method of combining the mechanical simulation and electrical simulation. In this method, it invites the test platform of electric bicycle brake force, and realizes the inertia simulation. On the test platform, the results showed: by using the electric inertia simulation, the performance of the system is obviously better than the one on the test platform which using flywheel groups. This method improves the degree of automation on the test platform.

Introduction

As the call of low carbon and environmental protection, National restrictions on private cars, the utilization rate of Electric bicycle is higher and higher. Safety requirements for electric bicycles will be too high as well. Therefore the braking performance requirements are very high. Brake manufacturer needs to perform various quality inspection and comprehensive evaluation of performance of the brake [1]. The ways to evaluate braking performance of electric bicycle are usually divided into three categories:

(l)Obtaining data of Electric bicycle in the practical road test to evaluate the electric bicycle brake performance. This can truly reflect the braking performance of electric bicycle.

(2)Set the electric bicycle brake force test platform of electric bicycle brake function of various parameters related. In the process of test, Take the different experimental methods according to the different test items test platform. To simulate a variety of road conditions of various parameter data and the electric bicycle brake performance assessment.

(3)Mathematical models are established according to the various test parameters. Simulation of dynamic process of electric bicycle braking simulation method by use of computer, then evaluating electric bicycle braking performance through the simulation data.

At present, brake bench test platform is commonly used as the traditional mechanical method. Through the rotary inertia large inertia wheel to simulate the mechanical inertia electric bicycle in motion process. But the torgue of inertia can hardly be continuously adjusted in the large inertia, and manufacturing cost is higher and not convenient to install. In view of the problems, with the design idea to develop an electric inertia simulation of mechanical inertia of the electric bicycle brake performance testing platform. According to certain control algorithm by motor output torque and rotational speed to simulate the mechanical inertia. Such devices occupy less space and money, and it can be continuously adjusted and convenient debugging.

Firstly, the traditional mechanical inertia simulation methods are briefly introduced. Then according to the principle of electric bicycle mechanical inertia of the electric simulation technology to make up the expression of the dynamic wheel in detail. Finally design the dynamic test platform and test platform for electric simulation system.

Traditional Mechanical Inertia Simulation Method

The use of mechanical inertia flywheel group to simulate is widely used traditionally. Using the test platform to simulate the electric bicycle mechanical inertia fly wheel. The fly wheel is made up of

multiple sizes of the flywheel. The test device combines with the main rolling chassis dynamometer through the clutch [2]. By controlling the number, size of the flywheel to simulate different inertia. The method has the advantages of simple operation, but the defects are showed as follows：its quality fixed once flywheel finished, This means that a testing platform once assembled, the simulation of quality fixed, unless the flywheel replaced, otherwise it cannot realize the diversification of demand; The flywheel mass is greater, the higher requirements of design and manufacturing, This will increase the cost of the whole system; Flywheels will produce large noise and vibration in the operation process. Once a mechanical fault, it may pose a threat to the surrounding the safety of equipment and personnel; The inertia of the flywheel equipment system is huge normally, and needs higher installation accuracy, thus the installation and replacement of the flywheel will take a long time.

Analyze The Technical Principle of Simulating A Electric Bicycle's Electric Inertia Instead of Mechanical Inertia

The core content determination of mechanical inertia use electrical simulation technology of electric has 2 points. First, to determine the mechanical inertia of bicycle. Second, electric simulation technology need to adopt electric drive system and make precise control of output torque, because different bicycle have difference inertia. Through the different tests results of a same t bicycle o adjust the speed and acceleration of the electric bicycle in the deceleration process. The above parameters can be measured by the torque, so the core problem of electric simulation technology of mechanical inertia is the control of torque [3].

The mechanical inertia simulation is the use of inertial rotation of the flywheel stored energy, in the test bed frame simulating various models of electric bicycle of equivalent quality on the road. Torgue $J\ (kg\cdot m^2)$ of inertia simulation test bench calculated as follows:

$$J = \frac{\eta}{1+\eta}(m_1 + 0.071m)r_k^2 \tag{1}$$

Where η is Electric bicycle wheel braking force distribution ratio before and after, m1 is the rated quality of electric bicycle, m is electric bicycle vehicle quality, rk is the wheel diameter of electric bicycle.

The spindle speed of inertia test platform by the following formula

$$n = 2.645v / r_k \tag{2}$$

Where v is the initial velocity of electric bicycle test.

The brake is loaded in pure flywheel inertia test platform, the relationship between its braking torque and inertia fly wheel and the rotational speed is as follows:

$$\alpha_j = \frac{d\omega}{dt} = \frac{M}{J} \tag{3}$$

Where α_j is the test platform frame spindle angular speed reduction. M is braking torque. ω is test platform frame spindle angular velocity.

By Eqs. (3), When the torgue of inertia J unchanged, braking deceleration is only related to braking torque. So the essence of the inertia brake test is to test the deceleration of the inertial system features, and then simulate the process of electric bicycle brake to slow down. Among them, torgue of inertia J is only for storing kinetic energy. If replace fly wheel stored kinetic energy with motor output energy, and keep the relationship between braking torque and speed reduction, can be used for simulating the mechanical inertia, called electrical inertia simulation. Electric inertia simulation process can be expressed as

$$M = M_1 + J_0 \frac{d\omega}{dt} \tag{4}$$

Where M_1 is the output torque in the process of motor brake. J_0 is the mechanical inertia of test platform that Including servo motor rotor, shaft coupling, main shaft and a fixed wheel inertia. M is a measured values, and can be used as a control volume.

By Eqs. (3), Substituting (dω/dt)=(M/J) into Eq. (4) and we can get the equation

$$M_1 = (\frac{J - J_0}{J})\,\mathrm{M} \tag{5}$$

J and J_0 are known in Eqs. (4). Therefore, the so-called electric simulation is through control the output torque of motor M_1 and make the tested brake have the same deceleration (dω/dt) with purely mechanical simulation system.

In known braking deceleration (dω/dt), the relationship between the brake on the brake torque M and the output torque of the motor M_1 the total inertia J and the basic inertia J_0 as follows:

When $J=J_0$, the mechanical inertia simulation of inertia is equal to the system, is the mechanical simulation system, the output torque of the motor is zero.

When $J<J_0$, M_1 is negative, the motor output brake torque, the direction of torque and rotate is opposite.

When $J>J_0$, M_1 is positive, the motor output Driving torque, the direction of torque and rotate is uniform.

Electrical analog control steps are as follows. First, measure the braking torque M. Second, calculate the output torque M_1 of the motor in the brake according to Eqs.(5). Third, By D/A conversion output electric inertia means the output torque M_1 of the motor in the brake. The sampling interval from the measurement to the output is short, it depends on the calculation speed of the computer and generally no more than 50ms.

A Structure Design For Braking Test Platform

In order to give full play to the function of electric bicycle testing existing test platform, electric inertia test platform on the basis of existing test bench can classify the function and design. Brake test system consists of test machine and computer control system. Test system Schematic diagram of the host structure is shown in Fig. 1, it can describe electric inertia test platform of the whole machine structure. Control system structure is shown in Fig. 2.

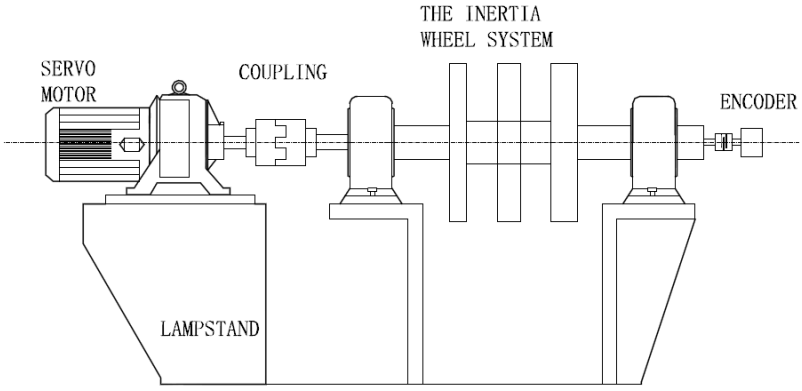

Fig. 1.Test system Schematic diagram of the host structure

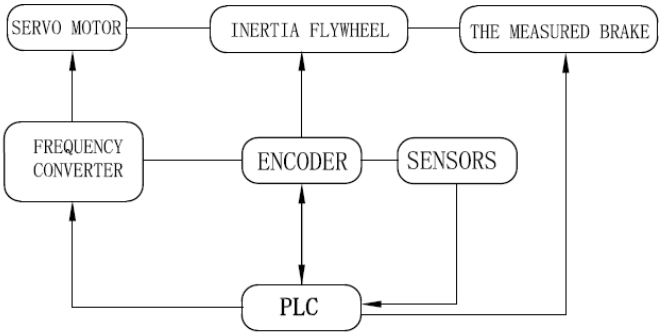

Fig. 2.Control system structure

The test system comprises a servo motor, inertia flywheel, transducer, encoder, sensor, PLC etc. In the development of the electric bicycle brake test-bed design combined with mechanical and electrical simulation method. During the test, the measured brake clamp on the test bed according to the installation as the electric bicycle. Motor drive shaft rotates, when it reaches to the speed of simulated electric bicycle. The control force is applied to the brake control force, making brake braking torque, forcing spindle stop [5]. DC speed regulating device to control the rotation of the DC motor. The encoder will dynamic speed feedback to the device and computer DC speed regulation, form a closed-loop control system. Applying pressure to the brake of the brake control force for a given organization is the pneumatic servo system controlled by computer, it can accurately simulate the brake operating force in actual driving. Test to measure the brake shoe temperature using thermocouple, thermocouple installed in the brake disc or drum brake shoe of the specified location. Brake temperature rise, and flooding after all can produce braking efficiency of the recession, it makes a strong impact on the safety performance in actual driving. So required by the test of brake blowing wind speed is accurately controlled by computer. In the water recession test, water spray for the brake can also be accurately controlled by computer. QC/T654-2005 Standard specified the test initial conditions, the braking original speed and braking deceleration, initial temperature, etc, which can be set whether the different models of the brake.

A Design for Electrical Simulation System of The Test Platform

When designing electric bicycle brake test bench, the first to determine the types and specifications of motor, its torque characteristics can be found from the product manual or the samples. Fig. 3 is the torque characteristic curve of the 30 kW DC motor. As can be seen from the Fig. 3 , the motor base speed is 600 r/min, the maximum speed is 1500 r/min. In the base speed zone, the maximum torque that motor can output is constant, the output power linearly increase gradually, so the base speed area is known as the constant torque area;When the motor speed exceeds the base speed, the maximum output power of the motor is constant, the maximum output torque curve gradually decline, so this area is called the constant power area. And the maximum torque corresponding to a speed point is the velocity and the corresponding power point torque value, can be calculated by the formula $M_1 = \frac{9550P}{n}$. (6)

Substituting it into equation (5) can take:

$$M = 9550\frac{P}{n}(\frac{I}{I - I_0}) \quad . \tag{7}$$

Practice proves that the combined system consisting of several additional inertia flywheel (as shown in Fig. 1), can expand the inertia simulation scope of platform. A combination of both can eliminate the differential, and reduce the test volume, improve simulation accuracy. Electric bicycle inertia of Brake test bench simulated by flywheel system. The inertia wheel system is consist of 3 inertial wheel and 2electromagnetic clutch that mounted on the spindle, the quantity of combination flywheels is one, the activity flywheels is two. The inertia wheel is selected by the computer according to the parameters of set brake and electric bicycles, at the start of the experiment through the electromagnetic clutch automatic select inertia wheel [6]. The inertia wheel simulated inertia difference by electric inertia simulation compensation. The inertia wheel simulated inertia difference shall be compensated by the differential electrical inertia simulation.

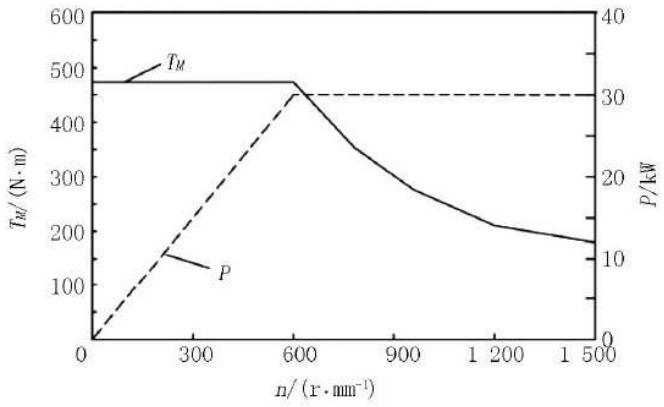

Fig. 3.The torque characteristic curve of the DC motor

The test uses the method of combining the mechanical simulation and electrical simulation. Precision of pure electric inertia simulation precision is low, and it uses Large capacity motor , Motor speed control device is of great capacity, These all will increase the cost. Simple mechanical inertia simulation requires many different inertia wheel in different combinations, and always exist analog differential, at the same time this makes the test bed volume very large. The combination of the two can eliminate the differential, reduces volume, improves the accuracy of the simulation and Save the cost. The testing system can simulate electric bicycle driving inertia in the series of 50 to 250.

Conclusion

The relationship between braking torque, the motor in the brake output torque and inertia simulation is given in this article through the analysis of the braking process of braking torque. The proposed method can effectively identify and optimize the mechanical inertia of the flywheel hybrid simulation system and driving motor matching relationship. Electric bicycle brake test platform that has been designed realized the simulation of inertia with the Methods of mechanical simulation and electrical simulation combined.

A Simple Criterion for Robust Stabilization Design of Interval Time-Delay Systems

Chien-Hua Lee[1,a] and Ping-Sung Liao[1,b]

[1]Department of Electrical Engineering, Cheng-Shiu University, Kaohsiung 833, Taiwan, R.O.C.

[a]chienhua@csu.edu.tw, [b]bsliao@csu.edu.tw

Keywords: robust stabilization; time-delay; interval system; Riccati equation approach; stabilizability criterion; decaying rate.

Abstract. This paper addresses the robust stabilization problem of interval time-delay systems. By applying an upper bound to the Riccati equation approach, a stabilizability condition and a controller are proposed. It is easy to test the presented condition and to implement the controller.

Introduction

In real-life systems, time delay and uncertainty exist naturally. Since both of them can lead to variations of eigenvalues and the loss of a certain amount of system accuracy, they hence are always sources of instability for controlled systems. Therefore, the robust controller design problem such that one can keep the inaccuracy to within an allowable bound becomes an attractive research topic. In literature, a number of works have adopted the LMI approach to solve the robust stabilization problem for uncertain systems with time-varying or time-invariant delay(s) [3-6]. In addition to the LMI approach, the Riccati equation approach has often been applied to solve the same problem for the aforementioned systems [1, 2, 7, 8]. However, most of those criteria and controllers obtained by this approach involve some modified Riccati equations which may be troublesome or even unsolvable. Among those works that use the Riccati equation approach, [8] applied an upper eigenvalue bound of the solution of the standard Riccati equation to the mentioned approach to develop a stabilizability condition and construct two stabilization control laws for uncertain time-delay systems. The obtained results can avoid the mentioned drawback. Therefore, the method presented in [8] can be considered as an improvement of the Riccati equation approach. In this paper, we extend the method proposed in [8] to solve the same problem of interval time-delay systems. However, we use a matrix bound to replace the eigenvalue bound that has been used in [8]. Then, a new stabilizability criterion and the corresponding control law can be obtained. When the interval system model is simplified to that presented in [8], comparison between the proposed stabilizability criterion and that of [8] will be made. It will be shown that the obtained result is sharper.

Main results

Consider the time-delay systems with parametric uncertainties

$$\dot{x}(t) = A_I x(t) + A_{dI} x(t-d) + B_I u(t). \tag{1}$$

where $x \in \Re^n$, $u \in \Re^m$, $d > 0$, respectively, denote the state, the input, and the delay, A_I, A_{Id}, and B_I represent interval matrices with appropriate dimensions and have the following properties:

$$A_I = [a_{Ipq}],\ u_{Ipq} \le a_{Ipq} \le v_{Ipq},\ p,q = 1,2,\ldots,n\ , \tag{1}$$

$$A_{dI} = [a_{dIpq}], u_{dIpq} \le a_{dIpq} \le v_{dIpq},\ p,q = 1,2,\ldots,n. \tag{2}$$

$$B_I = [b_{Ipq}], e_{Ipq} \le b_{Ipq} \le f_{Ipq},\ p,q = 1,2,\ldots,n. \tag{3}$$

For the above properties, we define the following matrices:

$$U = [u_{Ipq}], V = [v_{Ipq}], U_d = [u_{dIpq}], V_d = [v_{dIpq}], E = [e_{Ipq}] \text{ and } F = [f_{Ipq}]. \tag{4}$$

Define matrices A_i, A_{ij}, and, B_{ij}, respectively, as

$$A = 0.5(U+V),\ A_d = 0.5(U_d + V_d), \text{ and } B = 0.5(E+F). \tag{5}$$

Then, system (1) can also be represented as follows.

$$\dot{x}(t) = (A + \Delta A)x(t) + (A_d + \Delta A_d)x(t-d) + (B + \Delta B)u(t) \tag{6}$$

where (A, B) is assumed to be a controllable pair and ΔA, ΔA_d, and ΔB now denote the parametric uncertainties with the following properties:

$$\left[|\Delta A|\right] \le R, \left[|\Delta A_d|\right] \le S, \text{ and } \left[|\Delta B|\right] \le T \tag{7}$$

where $\left[|A|\right] = \left[|a_{ij}|\right]_{n\times n}$ means the modulus matrix of matrix A and R, S, and T are defined as

$$R = 0.5(V - U),\ S = 0.5(V_d - U_d) \text{ and } T = 0.5(F - E). \tag{8}$$

Once again, the application of the fact $\|A\| \le \left\|\left[|A|\right]\right\|$ results in

$$\|\Delta A\| \le \left\|\left[|\Delta A|\right]\right\| \le \|R\| \equiv \beta,\ \|\Delta A_d\| \le \left\|\left[|\Delta A_d|\right]\right\| \le \|S\| \equiv \gamma, \text{ and } \|\Delta B\| \le \left\|\left[|\Delta B|\right]\right\| \le \|T\| \equiv \eta. \tag{9}$$

It is assumed that the pair (A, B) is completely controllable. Then, the objective of this paper is to design a memoryless state feedback controller in the form of

$$u(t) = -Fx(t) \tag{10}$$

where F is the gain matrix such that the resulting closed-loop system is asymptotically stable.

By using linear algebraic techniques, a robust stabilization design for system Eq. 1 is given as follows.

Theorem 1. If there exists a positive constant η such that

$$A^T + A - \alpha BB^T + 2[\mu(R) + \gamma + \frac{\|A_d\|}{2}]I + \frac{A_d^T A_d}{\|A_d\|} + \alpha\eta\|B\| I < 0 \tag{11}$$

then the system (1) can be stabilized by a state feedback controller in the form of (11) with

$$F = 0.5B^T P \tag{12}$$

where the positive definite matrix P satisfies the Riccati equation

$$A^T P + PA - 0.5\alpha PBB^T P = -Q \tag{13}$$

where the $n\times n$ real positive definite matrix Q is given as

$$Q = \frac{\alpha}{2}\eta^2 q^2 I + q\left[(2\mu(R) + 2\gamma + \|A_d\|)I + \frac{A_d^T A_d}{\|A_d\|}\right] \tag{14}$$

and constant $q > 0$ is defined as

$$q = \frac{-\lambda_1(M)}{\alpha\eta^2} \quad \text{with} \quad M \equiv A^T + A - \alpha BB^T + \frac{A_d^T A_d}{\|A_d\|} + [2\mu(R) + 2\gamma + \|A_d\|]I. \tag{15}$$

Proof. Let a positive semi-definite matrix W is defined by

$$W \equiv 0.5\alpha(P - I)BB^T(P - I). \tag{16}$$

Then, we can rewrite the Riccati equation (14) as

$$(A - \frac{\alpha}{2}BB^T)^T(qI - P) + (qI - P)(A - \frac{\alpha}{2}BB^T) = -W + Q + \frac{\alpha}{2}BB^T + q(A^T + A - \alpha BB^T). \tag{17}$$

In light of (15), w have

$$Q + \frac{\alpha}{2}BB^T + q(A^T + A - \alpha BB^T)$$

$$= \frac{\alpha}{2}\eta^2 q^2 I + q\left[A^T + A - \alpha BB^T + (2\mu(R) + 2\gamma + \|A_d\|)I + \frac{A_d^T A_d}{\|A_d\|}\right] + \frac{\alpha}{2}BB^T. \tag{18}$$

From (19), (16) and using the fact that $K \le \lambda_1(K)I$ where K is a real symmetric matrix, we have

$$Q + \frac{\alpha}{2}BB^T + q(A^T + A - \alpha BB^T) \le \frac{1}{2}\left[\alpha\eta^2 q^2 + 2\lambda_1(M)q + \alpha\|B\|^2\right]I. \tag{19}$$

Condition (12) implies that $\lambda_1(M) < 0$. Applying (16) to (20) results in

$$Q + \frac{\alpha}{2}BB^T + q(A^T + A - \alpha BB^T) \le \frac{1}{2\alpha\eta^2}\left[-\lambda_1^2(M) + \alpha^2\eta^2\|B\|^2\right]I. \tag{20}$$

Obviously condition (12) can guarantee that the right-hand side of (21) is a negative definite matrix. Furthermore, it also infers that $(A^T + A - \alpha BB^T) < 0$ and then one can conclude that the matrix $A - 0.5\alpha BB^T$ is stable. Therefore, equation (18) is a Lyapunov equation and then the solution $(qI - P)$ of this Lyapunov equation is positive. That is, the solution of the Riccati equation (18) has

$$P < qI . \tag{21}$$

Using the controller (11) with (13), then system (1) becomes

$$\dot{x}(t) = [A + \Delta A - \frac{\alpha}{2}(B + \Delta B)B^T P]x(t) + (A_d + \Delta A_d)x(t-d) . \tag{22}$$

For this system, we construct a Lyapunov function as

$$V(x(t),t) = x^T(t)Px(t) + q\int_{t-d}^{t} x^T(\tau)(\frac{A_d^T P A_d}{\|A_d\|} + \frac{\Delta A_d^T P \Delta A_d}{\gamma})x(\tau)d\tau \tag{23}$$

where $P > 0$ satisfies (14). We also use symbols V, x, and x_d to replace $V(x(t),t), x(t)$, and $x(t-d)$, respectively. Now, taking the derivative along the trajectories of (1) gives

$$\dot{V} = x^T[(A + \Delta A)^T P + P(A + \Delta A) - \alpha PBB^T P + \frac{A_d^T P A_d}{\|A_d\|} + \frac{\Delta A_d^T P \Delta A_d}{\gamma}]x - \frac{\alpha}{2}P(\Delta BB^T + B\Delta B^T)P$$

$$- x_d^T(\frac{A_d^T P A_d}{\|A_d\|} + \frac{\Delta A_d^T P \Delta A_d}{\gamma})x_d + x_d^T(A_d + \Delta A_d)^T Px + x^T P(A_d + \Delta A_d)x_d . \tag{24}$$

Since

$$-P\Delta BB^T P - PB\Delta B^T P \le PBB^T P + P\Delta B\Delta B^T P , \tag{25}$$

$$x_d^T A_d^T Px + x^T PA_d x_d \le \frac{1}{\|A_d\|}x_d^T A_d^T PA_d x_d + \|A_d\| x^T Px , \tag{26}$$

$$x_d^T \Delta A_d^T Px + x^T P\Delta A_d x_d \le \frac{1}{\gamma}x_d^T \Delta A_d^T P\Delta A_d x_d + \gamma x^T Px , \tag{27}$$

then

$$\dot{V} < x^T[A^T P + PA - \alpha PBB^T P + \Delta A^T P + P\Delta A + \frac{A_d^T PA_d}{\|A_d\|} + \|A_d\| P + \frac{1}{\gamma}\Delta A_d^T P\Delta A_d + \gamma P$$

$$+ \frac{\alpha}{2}PBB^T P + \frac{\alpha}{2}P\Delta B\Delta B^T P]x \tag{28}$$

If condition (12) is satisfied, then the upper bound (22) exists and (25) becomes

$$\dot{V} < x^T[-Q + q(\Delta A^T + \Delta A + \frac{A_d^T A_d}{\|A_d\|} + \|A_d\| I + \frac{1}{\gamma}\Delta A_d^T \Delta A_d + \gamma I + \frac{\alpha}{2}q\eta^2 I)]x$$

$$\le x^T[-Q + q(2\mu(R) + \|A_d\| + 2\gamma)I + q\frac{A_d^T A_d}{\|A_d\|} + \frac{\alpha}{2}\eta^2 q^2 I]x = 0 . \tag{29}$$

Where relation (15) and the following inequality are used.

$$\Delta A^T + \Delta A \le 2\mu(\Delta A)I \le 2\mu(|\Delta A|)I \le 2\mu(R)I \tag{30}$$

Therefore, the resulting closed-loop system (23) is robustly stable. Thus, the proof is completed.

In the literature, [8] has discussed the following uncertain time-delay system

$$\dot{x}(t) = (A + \Delta A(k(t)))x(t) + (A_d + \Delta A_d(r(t)))x(t-d) + Bu(t) . \tag{31}$$

Then, a stabilizability criterion for system (32) has been derived as

$$\lambda_1(A^T + A - \alpha BB^T) + 2(\beta + \bar{\gamma} + \|A_d\|) < 0 \tag{32}$$

where positive constants β and $\bar{\gamma}$, respectively, are defined by

$$\beta \equiv \sup_{t\in\mathbb{R}^+}\|\Delta A(k(t))\| \text{ and } \bar{\gamma} \equiv \sup_{t\in\mathbb{R}^+}\|\Delta A_d(r(t))\| .$$

Let $\Delta A = \Delta A(k(t)), \Delta A_d = \Delta A_d(r(t))$ and $\Delta B = 0$. Then system (7) becomes system (32). Besides, using the relation $\mu(\Delta A(r(t))) \le \|\Delta A(r(t))\| \le \beta$, condition (12) now becomes

$$A^T + A - \alpha BB^T + 2[\beta + \overline{\gamma} + \frac{\|A_d\|}{2}]I + \frac{A_d^T A_d}{\|A_d\|} < 0 . \quad (33)$$

In light of the relation $A_d^T A_d \le \lambda_1(A_d^T A_d)I = \|A_d\|^2 I$ and the inequality $\lambda_1(A+B) \le \lambda_1(A) + \lambda_1(B)$ for $A^T = A$ and $B^T = B$, we have

$$A^T + A - \alpha BB^T + 2(\beta + \overline{\gamma} + \frac{\|A_d\|}{2})I + \frac{A_d^T A_d}{\|A_d\|} \le \lambda_1[A^T + A - \alpha BB^T + 2(\beta + \overline{\gamma} + \frac{\|A_d\|}{2})I + \frac{A_d^T A_d}{\|A_d\|}]I$$

$$\le \lambda_1(A^T + A - \alpha BB^T)I + 2(\beta + \overline{\gamma} + \|A_d\|)I . \quad (34)$$

Therefore, it is obvious that condition (34) is sharper than (33).

Conclusion

In this paper, the robust stabilization problem for interval time-delay systems has been addressed. By applying an upper matrix bound and linear algebraic techniques to the Riccati equation approach, the mentioned problem is solved. A simple criterion and the corresponding memoryless state feedback controller have been presented to guarantee the asymptotic stability of the resulting closed-loop systems. It is shown that they are easy to be tested and implemented. From a comparison, it is shown that the obtaining condition is sharper than that proposed in [8] for systems without input uncertainty.

Keywords: Thermal barrier coatings, Microwave NDE, Optimization, Operation frequency

Abstract: Thermal barrier coatings (TBCs) were developed to increase the operating temperatures of turbine blades in gas turbine engines. Non-contact inspection and the ability to penetrate into dielectric materials are two of the most important attributes of microwave non-destructive evaluation (NDE) and make it suitable for the non-destructive inspection of TBCs. In order to improve the detection sensitivity, it is important to optimize operation frequency. Computer simulation technology-microwave studio (CST-MWS) was used to optimize operation frequency in the evaluation of the top coating (TC) porosity and the metal substrate surface defects using microwave NDE. The results showed that the sensitive frequency is different when the TC thickness of under detection changes. So, it is necessary to choose appropriate operation frequency according to TC thickness to evaluate TBCs using microwave NDE.

1．Introduction

Thermal barrier coatings (TBCs) are used to achieve higher overall efficiency for aircraft engines and land-based gas turbine systems. However, the characteristics of TBCs are influenced of the spraying parameters and the work environment. Despite the considerable progress that has been made in the last few years, non-destructive evaluation (NDE) techniques of characterizing coatings, such as piezospectroscopy, eddy current, electrochemical impedance, etc., are still unable to provide a sufficiently precise description of a multilayer system [1]. Non-contact inspection and the ability to penetrate into dielectric materials are two of the most important attributes of microwave NDE and make it suitable for the non-destructive inspection of TBCs. The thickness of TBCs, defects on substrate interface, cracks and pores of TC can be easily visualized using microwave scanning probe [2]. The phase and magnitude of the microwave reflection coefficient can evaluate the TBCs delamination induced by acute angle laser drilling using microwave NDE [3]. The phase difference of microwave reflection coefficient can be used to evaluate the thickness of TC and TGO in TBCs using microwave NDE operating over K- and W-band frequency range [4]. A good resolution of 1º change in phase for 8μm TC thickness was obtained when the TC thickness was evaluated using microwave NDE [5]. Reflection coefficient is a function of various parameters such as, dielectric layer's thickness, standoff distance, dielectric properties, operation frequency, etc. Therefore, by measuring the reflection coefficient under certain conditions, it is possible to evaluate the above parameters. When an in-contact inspection technique was applied for detecting and evaluating the characters of TBCs, the operation frequency is one of the major factors to affect the reflection coefficient. In order to improve the detection sensitivity, it is important to optimize operation frequency.

In this paper, Computer simulation technology-microwave studio (CST-MWS) was used to optimize operation frequency in the evaluation of the top coating (TC) porosity and the metal substrate surface defects using microwave NDE. The results revealed that the U-band frequency should be used to detect TBCs when the TC thickness was from 300μm to 350μm and the Ka-band frequency should be used to detect TBCs when the TC thickness was from 400μm to 500μm.

2. Theoretical bases

The problem of transmission and reflection of uniform plane waves from a multilayer dielectric medium has been investigated by many investigators. This microwave NDE is based on wave reflection from a dielectric media interface. Metallic BC thickness does not affect microwave signals, so, in this case, TC was deposited directly onto the metal substrate. Uniform waves were normally incident into the TC system and then reflected by the metal surface (good conductor layer). These forward- and backward- traveling waves inside the TC layer were formulated by enforcing the appropriate boundary conditions at the air-TC and TC-conductor boundaries. Finally, the reflection coefficient was set as the ratio of the reflected and incident waves [6]. Figure 1 shows the incident and reflected electric fields traveling in TC systems: the incident electric fields of the probe, E_0^i(Vm^{-1}), that incident into TC system, E_{TC}^+, and that reflected by the metal surface, E_{TC}^-. After being completely reflected by the TC and substrate, the field emerged as a reflected electric field in the probe, E_0^r. The reflection coefficient is the ratio of E_0^r and E_0^i. The reflection coefficient Γ and its phase ϕ at the sensor aperture can be written as follows:

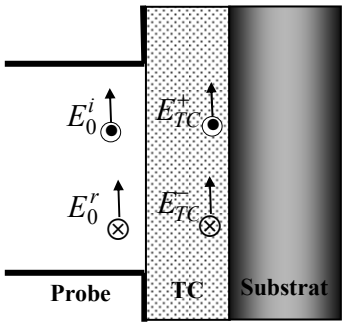

Fig. 1 Incident and reflected electric fields traveling in TC systems consisting of a rectangular waveguide probe and TC backed by a conducting metallic substrate

$$\Gamma = \frac{E_0^r}{E_o^i}$$
$$\phi = \tan^{-1}\left[\frac{\mathrm{Im}(\Gamma)}{\mathrm{Re}(\Gamma)}\right] \quad (1)$$

When microwave signals travel within TC systems, the permittivity of the TC affect the electric field, thereby affecting the reflection coefficient. In this study, TC porosity associated with TC permittivity can be informed by the reflection coefficient. Besides, the surface conditions of the metal substrate influence the reflection coefficient. So, the reflection coefficient was used to characterize the metal substrate defects.

3 CST model

CST-MWS is a specialized tool for the 3D electromagnetism (EM) simulation of high-frequency components. CST MWS' unparalleled performance often makes it the

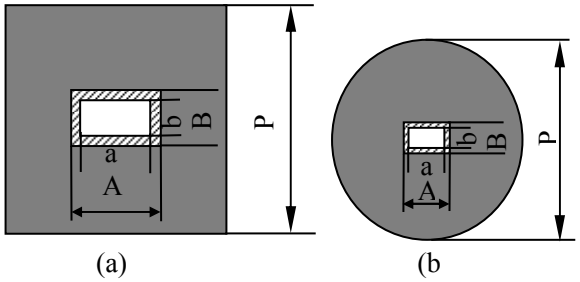

Fig. 2 The structures of rectangular waveguide probes (a) WR28, (b) WR18

first-choice technology in research and development departments. CST MWS enables fast and accurate analysis of high-frequency (HF) devices such as antennas, filters, couplers, planar and multi-layer structures. Exceptionally user friendly, CST MWS quickly gives researchers insight into the EM performance at high frequency. CST-MWS is seen as a standard industry development tool. M.T. Ghasr et al. simulated the reflection coefficient at the aperture of a probing open-ended waveguide using CST-MWS [7]. Ghasr's experimental results [8] were similar to [7] calculated results. Contact evaluation was used to evaluate TBCs using a rectangular waveguide probe. Two probes WR28 and WR18 were used. Figure 2 shows the structures of WR28 and WR18. Table 1 shows the size of the probes.

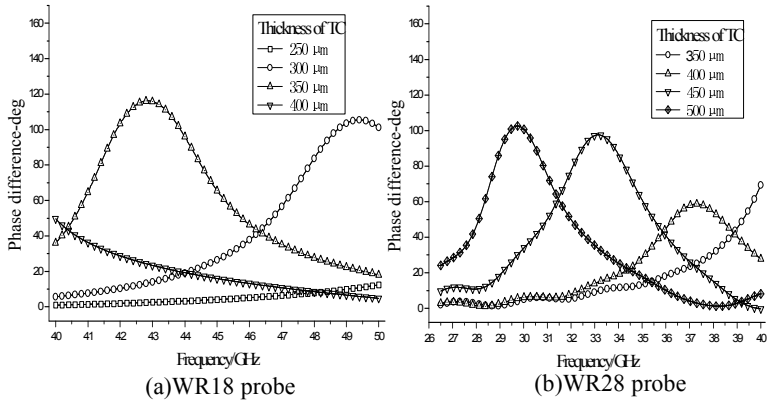
Table 1 Type and size of rectangular waveguide

Waveguide probe	a (mm)	A (mm)	b (mm)	B (mm)	P (mm)
WR28	7.112	9.14	3.556	5.59	19.1
WR18	4.775	6.81	2.338	4.42	28

4 Results and discussions

4.1 Detection of TC Porosity

The phase difference was calculated for TC of 10% relative to 3% porosity when TC thickness was kept constant within one group to limit its influence. Figure 3 shows the phase difference vs. frequency using two probes, WR18 and WR28. Figure 3 shows that the maximum phase difference in each phase difference curve and that TC thickness was equal to one quarter of the wavelength of the microwave when the microwave operated at the frequency corresponding to the maximum phase difference, which is called the sensitive frequency. Thus, under actual testing conditions, TC porosity was able to be determined using this microwave technique by selecting the appropriate frequency, which was estimated according to TC thickness. Once this was known, the appropriate waveguide probe was selected. The phase difference of the microwave reflection coefficient indicated TC porosity using probe WR18 when TC thickness was 300 to 350 μm, and probe WR28 when TC thickness was 400 to 500 μm.



(a)WR18 probe (b)WR28 probe

Fig. 3 Phase differences of 10% and 3% TC detected by (a) WR18 and (b) WR28 for TC of different thicknesses

4.2 Detection of Substrate Defects

When the subtract defect was detected using microwave technique, the characteristic of TBCs influence the evaluation results, because that microwave signals transmit in TBCs. The effect of the TBCs thickness was studied to optimize the operation frequency. Figure 4 showed that the phase

difference of TC between with defect and without defect vs. operation frequency. Figure 4(a) showed the phase difference detected by WR18 for different thickness TC. The results indicated that the phase difference curses have maximum evaluating 300μm and 350μm thickness TC. The frequency corresponding to the maximum phase difference is called the sensitive frequency. Figure 4(b) showed the phase difference detected by WR28 for different thickness TC. The results indicated that the phase difference curses have maximum evaluating 400μm, 450μm and 500μm thickness TC. The sensitive frequencies are relevant to the thickness of TC when the substrate defects are detected using microwave NDE.

5 Conclusions

Based on microwave communication and reflection theory in thermal barrier coatings on metal substrates, the optimization of operation frequency was presented in the evaluation of the top coating (TC) porosity and the metal substrate surface defects using microwave NDE. The results showed that the sensitive frequency is different when the TC thickness changes and that the greater the TC thickness, the higher the sensitive operation frequency. When the TC thickness was between 300μm and 350μm, U-band rectangular waveguide (WR28) was used to detect the TC porosity or the metal substrate defects. When the TC thickness was between 400μm and 500μm, Ka-band rectangular waveguide (WR18) was used to detect the TC porosity or the metal substrate defects. Special study is needed to distinguish the TC porosity and the substrate defects.

Keywords: honeycomb sandwich panel, damage detection, frequency dactylogram.

Abstract. An aluminous honeycomb sandwich panel with some structural damages was selected as the objective in this study. The panel was simply supported along four edges and its natural frequency data was collected through modal experiment with a hammering method. Application of frequency dactylogram method for honeycomb sandwich panel damage is identified. The detection results show that the frequency dactylogram method can be constructed using the frequency data of honeycomb sandwich panel, which is only related with the positions of damage and not the degree of damage.

Introduction

Currently, most of the study about the honeycomb sandwich structure damage is focused on the damage mechanism and repair [1, 2]. Engineering often use visual method, hammer percussion method and acoustic resistance meter detection method, X-ray method to check out whether there is any damage. However, the literatures which do research about honeycomb sandwich structure damage detection based on the dynamic characteristics were rare. The technology of structure damage detection which based on dynamic test is a global damage detection technology. The basic idea is that the structure damage is bound to cause the changes of some structure parameters, such as weight, the stiffness and damping. Then resulting in the changes of structural of dynamic characteristic (modal parameters and frequency response function, etc.), while the structure dynamic characteristics is the intrinsic characteristics of the structure, only the structure changes (components damage), the condition of its dynamic characteristics will change, so we can determine the structure damage by studying the change of parameters of the structure dynamic characteristics. Damage diagnosis method based on structural dynamic characteristics is now under the attention of scholars at home and abroad, and will become the focus of the study.

By using the frequency data of the structure, we can only construct frequency dactylogram related with the damage location and not the degree of damage [3-8]. Frequency dactylogram can be used to locate the structural damage. Whether the structure damage exists or not can be determined by the comparison between the frequency which is observed currently and the former one. Therefore, it is an effective way to detect the structure damage only by using the data of frequency [9].

Basic principle of frequency dactylogram

If the structure with multiple degrees of freedom is in good condition, then the motion equation of free vibration is

$$(K-\lambda M)\phi=0 \tag{1}$$

While the damage exists, the rigidity of structure K and weight M will have little changes ΔK and ΔM, according to perturbation theory, equation (1) can be

$$((K+\Delta K)-(\lambda+\Delta\lambda)(M+\Delta M))(\phi+\Delta\phi)=0 \tag{2}$$

In this paper, most of the study of the damage of honeycomb sandwich panel is minor damage. So, ΔM=0. Launch equation (2) and omit the second order, it will be

$$\Delta\lambda = \phi^T \Delta K \phi \Big/ \left(\phi^T M \phi\right) \tag{3}$$

Therefore, the changes of eigenvalue in modal at In-order can be written as

$$\Delta\lambda_i = \phi_i^T \Delta K \phi_i \Big/ \left(\phi_i^T M \phi_i\right) = \sum_n \phi_i^T \Delta K_{nl} \phi_i \Big/ \left(\phi_i^T M \phi_i\right) \tag{4}$$

Among the equation: ΔK_{nl} is the rigidity changes of the element *(n, l)*.

Only the element (*n, l*) damaged, the equation should be changed as

$$\Delta\lambda_i = \phi_i^T \Delta K_{nl} \phi_i \Big/ \left(\phi_i^T M \phi_i\right) \tag{5}$$

Consider the damage factor of element (*n, l*) is α, then $\Delta K_{nl}=\alpha K_{nl}$, the equation (5) will be

$$\Delta\lambda_i = \alpha \phi_i^T K_{nl} \phi_i \Big/ \left(\phi_i^T M \phi_i\right) \tag{6}$$

Equation (6) is the change of the eigenvalue in structure at In-order. Take any two eigenvalue of modal in structure $\Delta\lambda_i$ and $\Delta\lambda_j$, their rate is

$$\frac{\Delta\lambda_i}{\Delta\lambda_j} = \left(\frac{\phi_i^T K_{nl} \phi_i}{\phi_i^T M \phi_i}\right) / \left(\frac{\phi_j^T K_{nl} \phi_j}{\phi_j^T M \phi_j}\right) \tag{7}$$

Combined with (2), it can be deduced that $\Delta\lambda=(\omega+\Delta\omega)^2-\omega^2$, omit the second order, then $\Delta\lambda=2\omega\Delta\omega$, substitute $\Delta\lambda=2\omega\Delta\omega$ into equation (7) and we can sort out that:

With and without the structure damage, the rate of any two orders of frequency changes is

$$RCF_{ij}^{nl} = \frac{\Delta\omega_i}{\Delta\omega_j} = \frac{\left(\frac{\phi_i^T K_{nl} \phi_i}{\phi_i^T M \phi_i}\right) / \omega_i}{\left(\frac{\phi_j^T K_{nl} \phi_j}{\phi_j^T M \phi_j}\right) / \omega_j} \tag{8}$$

With and without the structure damage, the rate of any regularized frequency at the first order is

$$NRF_i^{nl} = \frac{\Delta\omega_i / \omega_i}{\sum_{j=1}^{q} \Delta\omega_j / \omega_j} = \frac{\left(\frac{\phi_i^T K_{nl} \phi_i}{\phi_i^T M \phi_i}\right) / \omega_i^2}{\sum_{j=1}^{q} \left[\left(\frac{\phi_j^T K_{nl} \phi_j}{\phi_j^T M \phi_j}\right) / \omega_j^2\right]} \tag{9}$$

Among this: q is the order of the vibration mode and the frequency; the vibration mode Φ, frequency ω, rigidity K and weight M .These parameters are from nondestructive structure; K_{nl} is the structure rigidity when element (*n, l*) was damaged.

Equation (8) and (9) shows that, with and without the structure damage, any two orders of the frequency changes' ratio, the rate of any regularized frequency at the first order do nothing with the degree of the structure damage, and is connected with the location of the damage. Therefore, these two parameters can be used to construct the location of structure damage.

Numerical examples validate of frequency dactylogram damage detection

Because of the complexity of the panel structure and boundary conditions, we use the beam structure to analyze feasibility of the frequency dactylogram at first in this paper. The structure of composites beam is 350mm×25mm×25mm, the length of fixed support is 50mm, as Fig. 1. Among all the same size of composite beam specimen with damage, the distance of the damage location and free end is 125mm.

Use the finite element analysis method to calculate out the first three order natural frequency of composites beam with and without damage as Table 1.

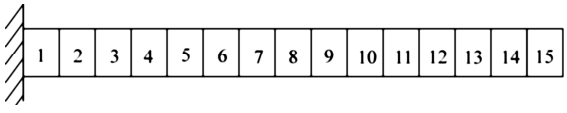

Fig. 1 Mesh and element number of composite beam

We can get the frequency of composite structure without damage and with each damaged element after calculation, as Table 2.

Table 1 Natural frequency of composites beam with and without damage

	Natural frequency /Hz		Rate of change of frequency for damage and without damage)/ %
	without damage	with damage	
First modal	33.69	33.45	-0.712
Second modal	207.72	205.57	-1.035
Third modal	574.74	570.99	-0.653

Table 2 Frequency of composite structure without damage with each damage element

		Natural frequency /Hz		
		first modal	second modal	third modal
Without damage		33.550	207.05	573.22
Number of element for damage	1	32.730	202.48	561.41
	2	32.790	203.70	565.59
	3	32.880	204.46	565.88
	4	32.940	204.60	563.93
	5	32.990	204.32	562.62
	6	33.040	203.84	563.35
	7	33.080	203.37	565.25
	8	33.107	203.09	566.25
	9	33.129	203.10	565.14
	10	33.144	203.36	562.86
	11	33.154	203.76	561.46
	12	33.159	204.16	562.09
	13	33.162	204.45	564.09
	14	33.163	204.58	565.73
	15	33.163	204.61	566.28

According to the result of calculate the vibration of beams, the rate of frequency changes is: Δf_1=-0.712%, Δf_2=-1.035%, Δf_3=-0.653% and the rate is: $\Delta f_2/\Delta f_1$=1.453, $\Delta f_3/\Delta f_1$=0.916.

Based on the finite element analysis, with the regularized coordinate of length in structure χ as abscissa, with frequency change ratio δ as the ordinate drawing a curve line of the location of damage-the frequency change ratio, then use the frequency change ratio which calculated through the results of experimental test, $\Delta f_2/\Delta f_1$=1.453, $\Delta f_3/\Delta f_1$=0.916, drawing two horizontal lines, and supersede it to the damage position-frequency change ratio curve, we can get 6 crossing points among the observation and the result calculated, as Fig. 2, two of the crossing points, the abscissa of point 3and point 4 are very close, the coordinate is the location the damage exists, the regularized coordinate is 0.56, transform it into physical coordinates is 168 mm, while the real location is 175 mm, considering the error of the experiment, it shows that the method is feasible.

It should be pointed out that, the premise of Eq. 8,9 are the structure of damage is minor, so minor data above the second order can be omit while carrying out the structure perturbation analysis. Thus,the conclusion we got is a approximate conclusion actually, the dactylogram of this conclusion largely depends on the damage location, meanwhile on the structure damage degree to some extent.

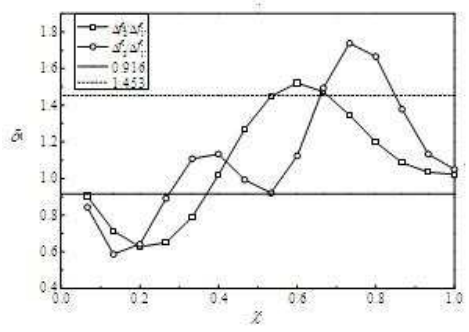

Fig. 2 Results of position finding of the damage

Frequency dactyllogram used for damaging location for honeycomb sandwich panel detection

The method carried out to collect the vibration modal data of the honeycomb sandwich panel is hammering method, the laboratory equipment contains force-hammer, piezoelectric accelerometer, DLF-3 four unification amplifier with double channel, INV3018C intelligently acquit and analyze signal instrumentand Coinv DASP MAS modal and dynamic analysis software. The materials chose in this experiment are aluminum cementing honeycomb sandwich panel. The size of its length and width is 200×200mm and the thickness of its is10mm. A fixturewith simply supported on four sidesis used in experiment. The structure data of honeycomb sandwich panel: the thickness of skin is 1mm, the thickness of honeycomb cell is 0.05mm, and the length of honeycomb cell is 6mm, as Fig. 3.

Fig. 3 Honeycomb sandwich panel and fixture with simply supported boundary in experiment

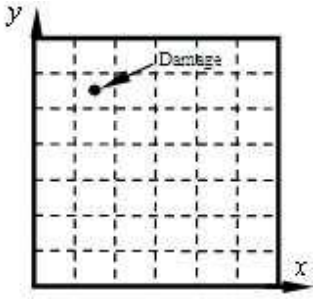

Fig. 4 Schematic diagram of the damage location for honeycomb sandwich panel

Divided the honeycomb into 7 elements along both the length and width direction, we got 7×7 elements. Because the method is only used to detect the honeycomb damage location, it has a tiny damage at the central of a quarter of honeycomb sandwich panel (the second element at x axis, the sixth element at y axis), as Fig.4.

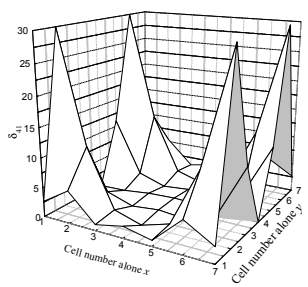
Use finite element analysis to calculate the first four order modal of each damage skin in the honeycomb sandwich panel, then collect the frequency dactylogram data of damage skin location in the honeycomb sandwich panel. The frequency dactylogram can be calculated through equation (8) and (9). The certain guiding principle can be followed while collecting the damage location dactylogram:

(a) Firstly, the accuracy of frequency dactylogram must be considered, generally speaking, the lower the frequency rate order is, and the better it will be;

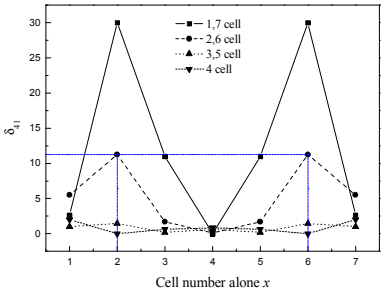
(b) The dactylogram with better monotonicity should be selected while using just one of the frequency dactylogram to detect the damage location;

(c) While using two or more frequency dactylogram to locate the damage, each one should be ensured and present reverse monotonic trend, meanwhile, pay attention to ensuring that there is enough distance among the dactylogram data of the same damage location.

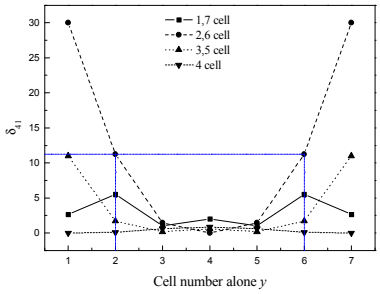
According to the principles above, selecting the results of calculated dactylogram in this paper is: the rate of frequency changes at the fourth order to the first order is δ_{41}, as Fig.5； the rate of the third order regularized natural frequency δ_{31}, as Fig.6.



(a) calculation results for along the *x* axis and *y* axis



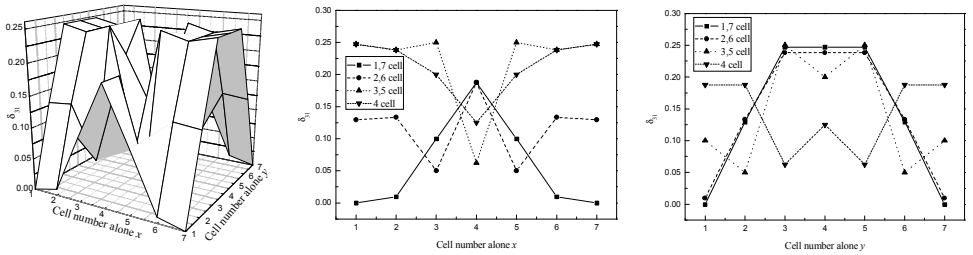
(b) calculation results for along the *x* axis



(c) calculation results for along the *y* axis

Fig. 5 δ_{41} of honeycomb panel frequency

The actual damage conditions dactylogram data of honeycomb sandwich panel which calculated through equation (8) and (9): frequency change ratio δ_{41}=11.82, regularized frequency change ratio δ_{31}=0.136. With the data of the honeycomb sandwich panel frequency change ratio δ_{41} and regularized frequency change ratio δ_{31}, draw a horizontal line at graph (b) and graph (c) in Fig.5 and Fig.6. The x-coordinate of crossing points on the horizontal and curve is the damage element.



(a) calculation results for along the x axis and y axis

(b) calculation results for along the x axis

(c) calculation results for along the y axis

Fig. 6 δ_{31} of honeycomb panel frequency

In graph (b) and graph(c) at Fig.5, while using the frequency change ratio δ_{41} to locate the damage, 4 damage elements can be determined: the two elements at intersection of second columns and second rows and intersection of second columns and sixth rows, the two elements at intersection of sixth columns and second rows and intersection of sixth columns and sixth rows. These location results not only determined that the element (2, 6) is the damage element correctly, but also determined another three elements which are symmetric with the element (2, 6).To locate the damage with regularized frequency change ratio δ_{31}, as the curve (b) and (c) in Fig.6 shows, the same results were determined. The reason: the three elements in the panel and element (2, 6) are symmetric, it is unable to distinguish the structure symmetric damage only based on frequency, and this is the shortcoming of frequency dactylogram. However, this positioning work is greatly convenient while using other ways to do the final confirmation of the damage location.

Summary

In this paper, we use frequency dactylogram to determine the minor damage of honeycomb sandwich panel, the position of damage can be determined more accurately by using the method which test the structure's natural frequency and combines the results calculated by finite element analysis, As for the symmetrical structure, such as the honeycomb sandwich panel with simply supported boundary , the damage detection results symmetrical with the real damage, it cannot shows the real position of damage intuitively, it contains the other three positions which is can help us narrow the range of damage detection.

Keywords: micro-channel, surface tension, droplets, laminar flow

Abstract. The phenomenon of laminar flow in the micro-channel is demonstrated by the software simulation. It shows different velocity produces different flow layer. Water-in-oil droplets are obtained by the experiments. These experiments take water as the dispersed phase and take the oil as the continuous phase. Analyze forming process and forming factors of the droplets and the column flow. The main factors of forming droplets are surface tension, viscosity shear force and the liquid velocity. The size of droplet is associated with the flow and channel width of two liquids. Changing the pressure of the inlet can obtain droplets in different size.

Introduction

Due to the particularity of micro-fluidic chip under the microscopic, using micro-fluidic chip which analyses and tests a cell and micro liquid drop, has received more and more attention. Therefore, another kind of droplet chip operation has appeared. It uses two incompatible liquid to form the micro droplets in the micro-channel. Digital micro-fluidic has wide application prospects in many fields, such as cell analysis, biomedical, clinical detection and so on.

According to the recent micro-droplet preparations, two kinds of micro-channel (T- slot and cross- slot) are widely used. Both channels can create droplet which can control the size and can create the laminar flow with phase flow also. Laminar flow can be used for the screening of cell and organic matter particles[1]. Droplets can be used in medical biological research, including the analysis of human mitochondrial DNA, the research of protein and the research of the separation and analysis amino acid[2,3]. In the micro scale, multiphase flow problem is the main research area[4]. Thorsen[5] is the first person who used T-shaped micro-channel to form droplets successfully. Shear force and surface tension are the main factors for the formation of droplets. By means of the study of T-slot, Garstecki[6] thinks that the shear stress is not the main factor for the formation of droplets. The main reason is that the dispersed phase blocking micro-channel leads to continuous phase pressure increased and reacts with interface tension, and then droplets form. Hua[7] thinks that droplet generation process is controlled by the viscous drag force and surface tension. High capillary number, continuous phase and dispersed phase under different flow rate, Amit Gupta[8]had studied flow mechanism for the two incompatible liquid with the interaction. In microscale multiphase flow channel, because there are crushing, shearing, jet and many other decentralized modes, can be obtained droplets flow, columnar flow, stratified flow and etc[9,10]. Regulated flow and material characteristics can let the fluid shape change come true[11,12].

Cross type structure is also called double T type structure. It can produce continuous mini droplets. Compared with T type structure, the cross structure can produce monodisperse micro droplets, and generate volume less than 1 liter micro-droplet.

Design micro-channel

Using of COMSOL geometry model tools can build two-dimensional model which corresponds to three-dimensional structure. Here sets entryway initial pressure values to 2 pa, 4 pa, 8 pa, 16 pa, in order to do the test. Setting the height of the channel cross section is High, the width of the channel cross section is Width, and the ratio of height and width is Ratio. The study shows that the

flow velocity will change correspondingly in the case of different pressure and different ratio of height and width, as shown in figure 1. When the depth-width ratio of the channel is 1:1, the slope of the fitting curve is the biggest and the velocity is the fastest. According to the results of the experiments, it can acquire the biggest velocity when the depth-width ratio of the channel is 1:1.

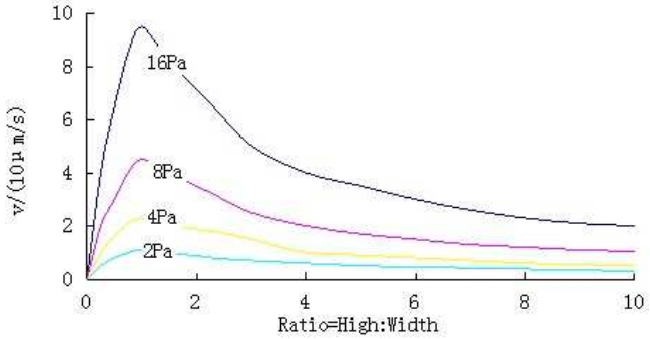

Fig.1 The different aspect ratio of the flow rate change in the microchannels

Same phase flow simulation

Laminar flow is hard to see in the experiment, so the effect can acquire clearly through the simulation. And the effect is as same as the experiment. To imitate three entrances and put the same fluid into these three channels, it can create three layers of non-interference. As shown in figure 2, the three channels have the same pressure.

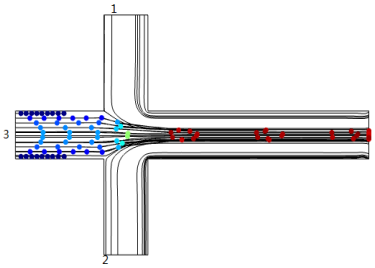

Fig.2 Three inlets have the same pressure

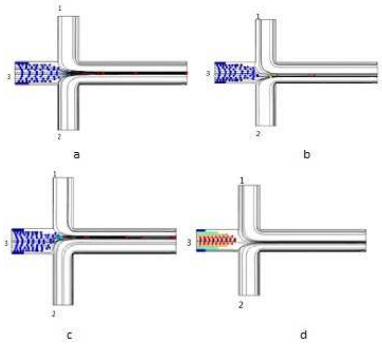

Fig.3 Change the pressure of channel inlet

Changing the pressure of three channels, only change the width and position of laminar flow, but the effect of laminar flow does not change. Figure 3a the up and down entrances pressures have increased, the middle entrance pressure does not change, it can be seen the middle laminar flow becomes thin. Figure 3b changing the up entrance pressure and other entrances pressure do not change, the middle laminar flow is biased below. On the contrary, is biased upward side. As shown in figure 3c.When the up and down pressures are far greater than the middle one, the middle fluid will be blocked. As shown in figure 3d.

Different phase flow experiments in cross-shaped microfluidic channel

When different liquids enter into the micro-channel, according to the theory of laminar flow, they are also the laminar flow. However, the test shows that the oil and water cannot produce laminar flow in some of the pressure and will create drops, because they have different viscosity and incompatible surface tension. Furthermore, when the water pressure is too large and far more than the oil pressure, it will appear the phenomenon of laminar flow.

Droplet formation process

Droplet formation process: When the cross channel is filled with oil, the two oil-way and reservoir are interlinked. The oil pressure has decreased, the water pressure won't change. Compared with the oil pressure, the water pressure are bigger than the oil pressure, the water will pour in the cross channel. As shown in figure 4a. Because the existence of the surface tension, the

front of the water column shrinks likes a water ball. The water pour into the cross channel again, the structure likes a ball will be increased. As shown in figure 4b. When the water sphere has increased to a certain degree, as shown in figure 4c, the water sphere has filled with the cross channel and jammed the two oil entrance. Then the oil pressure is larger than water pressure, the oil column began to squeeze water column. The water sphere has been flattened. As shown in the figure 4d. Under the shear of the oil, the water column has appeared to the bottleneck. As shown in the figure 4e. Water bottleneck is oppressed, and becomes very thin almost broken. As shown in the figure 4f. Finally, the water sphere will be cut and form a water column and pour into the reservoir. As shown in the figure 4g.

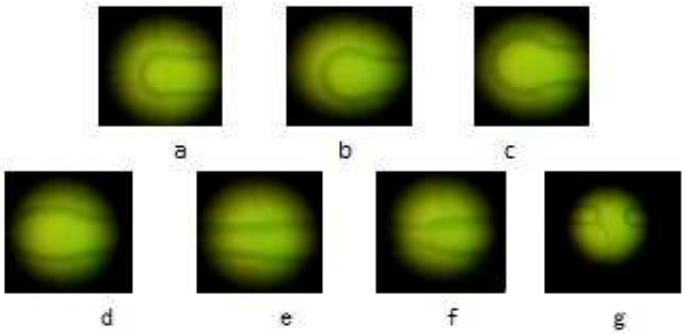

Fig.4 The process of droplet formation

The principle of droplet forming

Experiments show that the surface tension of the water and oil is the reason for the formation of droplets, in other way the pressure of the water and oil are alternating. Owing to water sphere jam the oil-way, it will form the pressure difference between the water and oil. Under the action of oil viscosity, cutting the water-way and forming the droplets.

When generating small droplets, they cannot be completely blocked the micro-channel cross structure and only rely on the flow shear stress. When the micro droplet is bigger, it can be completely blocked interleaving structure of cross channel, makes stress accumulates rapidly. Only smaller flow velocity can be free of surface tension and burst. If the oil and water flow rate ratio is too large, in other means the water pressure is bigger than the oil. The oil can't cut off the water.

As shown in the figure 8. The water is not cut off. The main reason is the water pressure is too big and the velocity ratio is too big. To solve this problem, it can increase the oil pressure and reduce the water pressure.

The formation of the laminar flow

During the experiment, it forms the laminar flow with some pressure. That is a water column wrapped in a layer film. As shown in the figure 5. The main cause of the laminar flow formation is water - oil pressure ratio is relatively large. The width of the laminar flow is different with the different of water - oil pressure ratio. With the increase of oil pressure, water laminar narrows, until the oil can cut off water laminar, form a small water column.

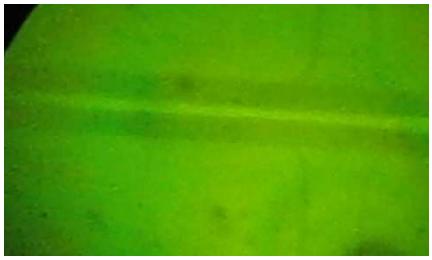

Fig.5 The formation of laminar flow

Factors affect droplet formation

The flow rate of the fluids impacts droplets size. Changing inlet pressure, liquids flow rate can be changed. In this paper, we do some experiments. The results of the experiment are similar as the literature[13].

Water-oil pressure ratio is 0.8, as shown the figure 6. It has small droplets. Water-oil pressure ratio is 1, as shown the figure 7. It has large droplets. When water-oil pressure ratio is 1.4, the liquid column is very long. When the water pressure is too big, it can hardly form the droplets and it will form the laminar flow. When the oil pressure is too big, the water won't flow. Take reasonable pressure ratio, the oil pressure is larger than the water pressure, in proportion to increase oil pressure and water pressure and it can quickly get uniform liquid droplets.

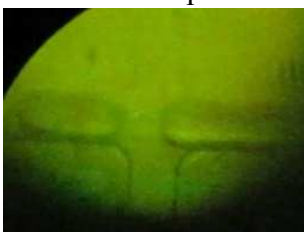

Fig. 6 The pressure ratio of water and oil is 0.8, L/W of the droplet is 1.8

Fig. 7 The pressure ratio of water and oil is 1, L/W of the droplet is 2

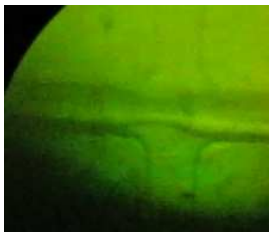

Fig. 8 The water pressure is too large, the flow is not cut off, droplets do not form

The figure 9, the oil pressure is constant, increasing the water pressure. The figure 10, the water pressure is constant, increasing the oil pressure. Fwater for water pressure, Foil for the oil pressure, L for the length of the droplets, W for the width of the channel. When the oil pressure is not change, with increasing of the water pressure, the length of the fluid column has increased. With decreasing of the water pressure, the length of the fluid column has decreased. When the water pressure is not change, with increasing of the oil pressure, the length of the fluid column has decreased. With decreasing of the oil pressure, the length of the fluid column has increased.

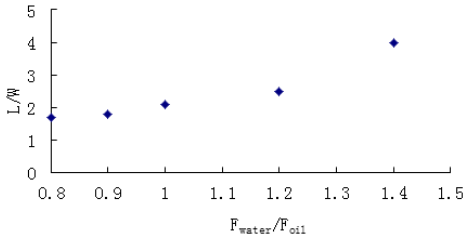

Fig.9 Oil pressure constant, increases the pressure of the water

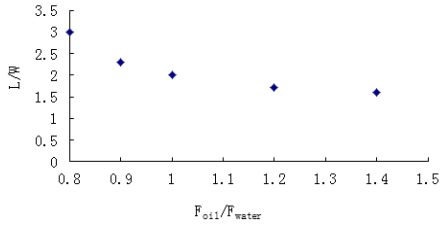

Fig.10 Water pressure constant, increases the pressure of the oil

The experiment shows that droplet formation is related to liquids viscosity, surface tension and liquids flow rate. The size of droplets is associated with channel and liquids flow rate. For the selected two kinds of liquids, as long as changing their feed pressure and then can get the required droplet. When generated the same size droplet, different viscosity of oil required for different feed pressure.

Conclusion

Using the cross slot can generate laminar flow and nanoliter droplets. For same kind fluid, controlling import flow velocity, it can control the width of the middle part. Laminar flow can be used to separate particles, such as cells, organic matter, etc. For multiple fluids, we can control the fluids pressure in order to generate controlled size of the droplets. The choice of the reasonable fluid, the reasonable velocity ratio and the reasonable channel, can obtain the droplets.

Research to the Model Design of Real Platform Based on the Simulating Network

LIU Guanqun[1, a]

[1]HuNan Radio&TV University, Changsha 410004,China

[a]LIUGuanqun05@yeah.net

Key words: Networked control systems; simulation; MATLAB; Winsock; networked control systems;

Abstract. One of the research works of network control systems is the effect of network upon control systems. A simulation platform of networked control systems is designed for this purpose. Matlab is used to build models of real systems. Communication between controller and process is fulfilled with Winsock. The simulation platform supports many control algorithms and gives good environment for the analysis and gives good environment for the analysis and design of networked control systems.

1. Introduction

With the development of society and the interesting competition, better result of control for process industry are required, including high profit, low cost, rapid feedback and so on. Industrial enterprises are required to apply more advanced control. It's significant to affirm the security and profit of advanced control. [3]Aim at the request of process industry, this paper put forward building an experimental platform for advanced control based on simulation training system. In order to affirm the security of advanced control and lower expenses of research, the experiment control should be done on the experimental platform before practical application. Thus it can accelerate the transformation of advanced control from theory to application. this paper gives an integrative introduction of process control, including the mission, request, development, actuality and the trend of process control, then it explains the necessity and feasibility of building the experimental platform for advanced control.

In the distributed control system, if the control loop sensor, actuator, and the controller are connected through a communication network, and control the controlled variable and the control variables in the system by the digital form is transmitted in the network, this system call control system for the network (NCS, networked control system). [1] Its typical structure is showed in figure 1. Because the control system is the exchange of information through the communication network, which can reduce the number of system connection, enhances the reliability and scalability of the system. With the falling price of related products in NCS network, compared with the traditional DCS, greatly reduces the cost of system. But on the other hand, because the network is introduced into the control loop, will inevitably increase the complexity of the system, most notably in real-time situations, the benefits of reducing the network control system simulation platform NCSS. [5] The structure highlights the actual network for control system analysis and design, and it is very helpful to NCS. On this basis, using some simple objects (such as motor) instead of simulation object, it can constitute a network control system.

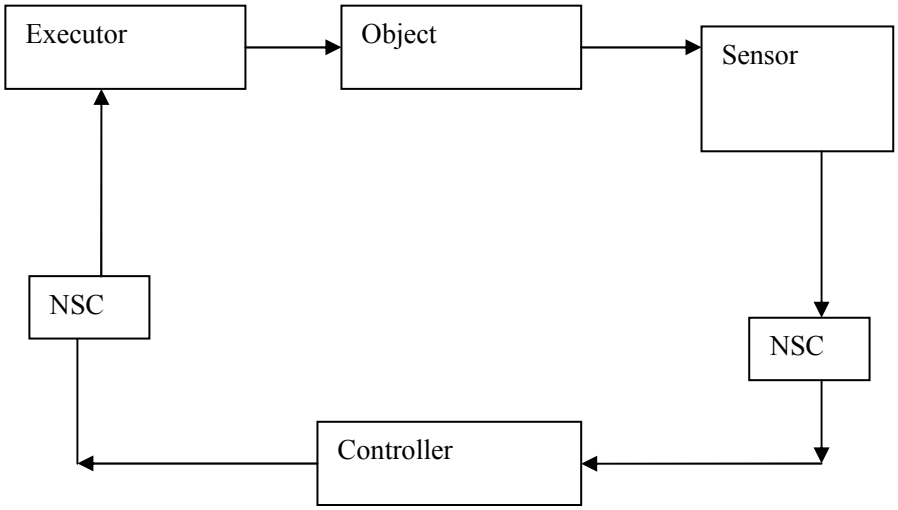

Figure 1 Network control system structure diagram [4]

Network control system simulation platform based on NCSS TCP/IP protocol, which can realize the software simulation of physical network all support TCP/IP protocol, analysis and design, and can directly use the Matlab and Simulink environment for network control system. By using the DSP control card, can also realize the remote control of the servo motor.

2. Scheme

Network with star structure, with the Cisco3550 switch as the central switchboard, using optical fiber jumper and Cisco2950G switch is connected with a uplink port, 100m extraoral even a server, the server through a broadband connection. Cisco 2950 switch and 3550 fast port connected, but also even under a TPLINK hub. As the PC network nodes can be connected to any port switches and hubs. PC machine is equipped with PCI-7841CAN bus card, you can use the CAN bus and F2407A DSP control card communication, and then realize control motor and stepper motor function. As shown in figure 2. [2]

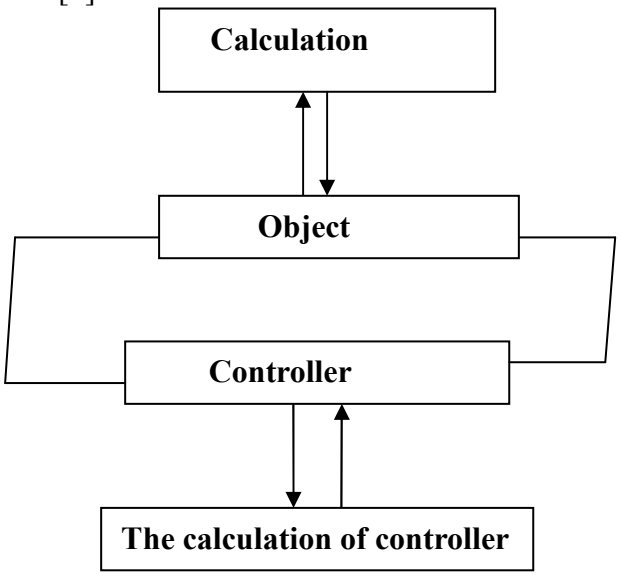

Figure 2 Network control system hardware structure

3. Network control system simulation platform

Based on the characteristics of NCS, we can study network combined with the simulation software of NCS, using PC as the network nodes, the simulation object and using software control method, simulation in the real network.

4. To construct the simulation platform

As the simulation software is currently the most popular, MATLAB plays an important role in control system analysis and design. Building on the foundation of MATLAB Simulink, can easily construct the control system model of complex; MATLAB toolbox and powerful computing ability, can achieve a variety of complex algorithms. But MATLAB itself does not provide communication interface, other methods must be used to achieve data exchange between nodes on the network. Windows socket (Winsock) defines the network programming interface of windows, and Microsoft MFC complex Winsock API package to the CAsynesocket class, which makes the preparation of web applications more easily. [1]Therefore, we can use the MATLAB structure of the actual object, used to simulate the actual object operation, and then through the MATLAB structure of the actual object, used to simulate the actual object, then the objects are transmitted to the Visual data by MATLAB C++ engine (VC) application program, VC program and then use Winsock to pass data to the remote controller operation, then use the same method to control the amount of applied to the object.

Simulation platform is constructed using this method, by using the powerful functions of MATLAB, the dynamic characteristics of the actual object to be as much as possible for real simulation, improved algorithm further research and provide a convenient. Simple controllers such as PID algorithm can be directly implemented in VC, the control complex algorithm can M files or Simulink model, called MATLAB therefore, software architecture is very flexible.[3]

5. Communication and simulation object and controller

The client or server communication mode is adopted between the object and the controller, the object for the server side, the controller as a client. In the control of the actual object, sensor, controller, actuator signal asynchronous, so CAsyncsocket needs to be placed in a non blocking mode, through the appropriate callback notification function call socket (such as OnReceive) to complete the asynchronous call. The Winsock API function with very rich, can also achieve some scheduling functions by calling the API function, such as Try-Once-Discard scheduling method. Communication between the object and the controller classes C pseudo code as shown in Table 1, where OnReceive the Winsock receives a message, and Ontimer timer message. [5]

Table 1 The controller classes C pseudo code

	}

6. Conclusion

Simulation of the actual object and controller based on MATLAB, to realize the communication between the network through the VC and Winsock, which formed a network control system simulation platform NCSS. The simulation platform structure is flexible, can simulate the real object and calls the various control algorithms based on MATLAB and C in a variety of physical network environment on the basis, analysis and design is very beneficial to network control system.

Keywords: Hybrid road approach, fatigue, road profile, TWR.

Abstract. Based on a hybrid road approach, a reliable process of fatigue load prediction is proposed. This approach known as Time Waveform Replication (TWR) relies on test data and multi-body model. The test data is used to back-calculate the hybrid road profile that will cause the same forces on the multi-body model. The road load is measured on the proving ground, and simulation of the multi-body model is ran by TWR to back-calculate the hybrid road profile. The simulation signals are verified by the experimental signals collected by wheel force transducers (WFT) and acceleration sensors.

Introduction

The durability of the automotive body is paid much more attention among the vehicle performance due to increasing demand of lightweight. In the early design stage, this is a key factor to reduce development time and cost. The fatigue loads that can accurately represent the field durability tests have an important role in the CAE analysis.

The hybrid approach known as TWR relies on test data and multi-body model [1]. The data collected on the proving ground is used to back-calculate the hybrid road profile (the equivalent spindle or vertical tire contact patch displacements) that will cause the same forces on the multi-body model. The approach is a Semi-Analytical method. It has several beneficial aspects with respect to the methods of Direct Measurement and Fully Analytical Road Load Data [2]. No dedicated prototype is needed, such as the tire model. Moreover it is well known that if the forces measured by WFT are applied directly to the unconstrained multi-body model, it will result in an un desired drift because of a mismatch in the mass and inertial properties between the real vehicle and its model.

In this study, a development process is proposed to accurately predict the fatigue loads for a commercial vehicle.

1. Full vehicle road test and virtual model

A vehicle test is conducted to collected load data on a proving ground. The wheel force transducers (WFT) are utilized to measure the wheel loading and acceleration sensors are also used to obtain the interesting signals. Fig. 1 shows the apparatus in the test. Signal processing should be done before applied to the virtual prototype, such as TimeEdit, Spike Filter, and Drift Correction.

Fig. 1 Wheel force transducer

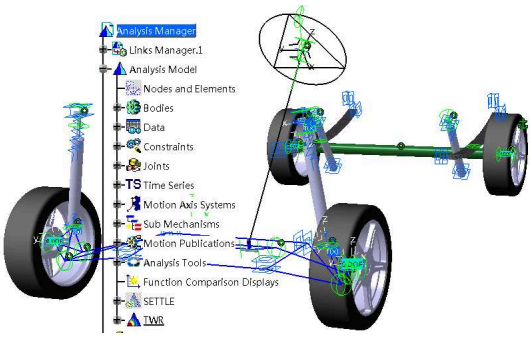

Fig. 2 LMS model for simulation

Considering hard point, mass parameters and nonlinear characteristic of bushing, the multi-body dynamics model of the vehicle is developed in the LMS environment (Fig. 2). The model mainly consists of a McPherson front suspension and a Hotchkiss LeafSpring rear suspension. In order to validate the model, a comparison of the axle weights between the model and real vehicle is conducted.

2. The hybrid road approach: Time Waveform Replication

The approach presented is similar to the set-up on a durability test rig. In fact, the hybrid road method is iterative back- calculate problem for a nonlinear system. TWR is the core technology that enables to compute a set of inputs (hybrid road profile) that will result in the response outputs at the relevant location on the model by multi-body simulation (MBS). A flowchart of the procedure with System Identification and Target Simulation [3] is provided in Fig. 3.

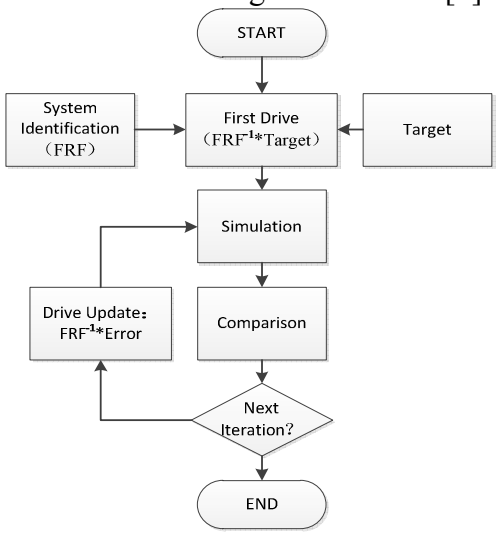

Fig. 3 Flowchart of the hybrid road method

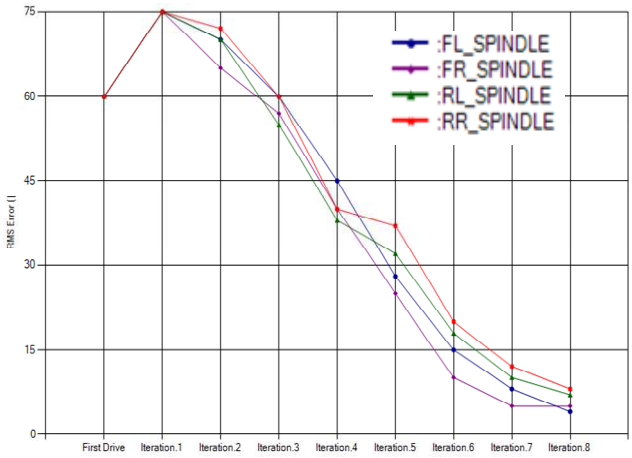

Fig. 4 Targets RMS

2.1 System Identification

The model is identified as a linear system by TWR. It's necessary to acquire a high quality Frequency Response Function (FRF) for the convergence of the result. Firstly, a reasonable White Pink Noise (WPN) is generated. The signal is defined by standard deviation, border frequency and power in the frequency domain. Secondly, the response output signal is obtained at the target location while the multi-body model is driven by WPN at the actuator location. The FRF is estimated from the time historied of the WPN and the responses according to equation [4] (1):

$$H(f)=\frac{G_{xy}(f)}{G_{xx}(f)} \tag{1}$$

Where $G_{xy}(f)$ is called cross-spectral density and $G_{xx}(f)$ is the input auto-spectrum.

2.2 Target Simulation

The target is a signal that has been measured in the road tests [5]. In general the real vehicle is nonlinear system due to the bushing and damper. And then the response from the System Identification differs from the test target. To cope with this problem, the Target Simulation is set up iteratively until the criterion is met. Firstly, the target signal multiplied by the inverse FRF is used to estimate the first drive signal followed equation (2).

$$u(t)=F^{-1}(d\bullet H(f)^{-1}\bullet g\bullet T(f)) \tag{2}$$

Where F is the Fourier transform, d is the Drive Gain, g is the Target Level, $T(f)$ is the target signal, $u(t)$ is the estimation of the first drive.

Secondly, the multi-body model is driven by the first drive to get the response signal, and then the error can be calculated between the response and the target.

$$e(f)=F(g\bullet T(t)-y(t)) \tag{3}$$

Where $T(t)$ is the target signal in time domain, $y(t)$ is the response signal and $e(f)$ is the error in frequency domain.

Lastly, error is used to update the drive signal until it is below an acceptable threshold followed equation (4).

$$u(t)_{i+1} = u(t)_i + F^{-1}(d \bullet H(f)^{-1} \bullet k \bullet e(f)) \tag{4}$$

Where the index i is the iteration, k is the error gain， this is a constant value between 0 and 1, like d and g， which can control the convergence[3].

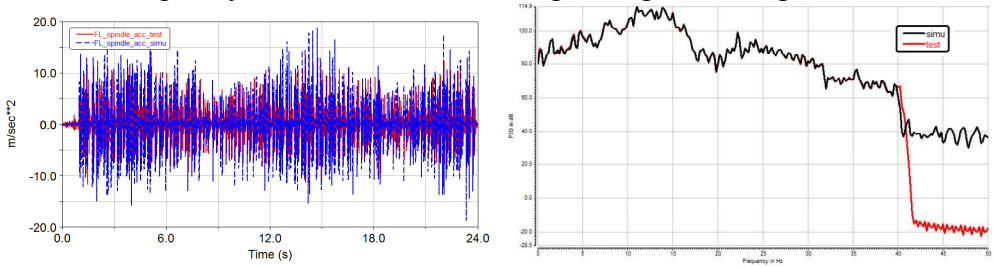
Some indexes that we pay more attention are calculated to evaluate the quality of the every iteration. In particular the time histories/PSDs of the responses and the targets can be overlapped, and the RMS of the error for each channel is evaluated according to equation (5) [6]. Generally the iteration can be accepted while ε <10%.

$$\varepsilon = \frac{RMS(e(t))}{RMS(T(t))} \tag{5}$$

2.3 Application

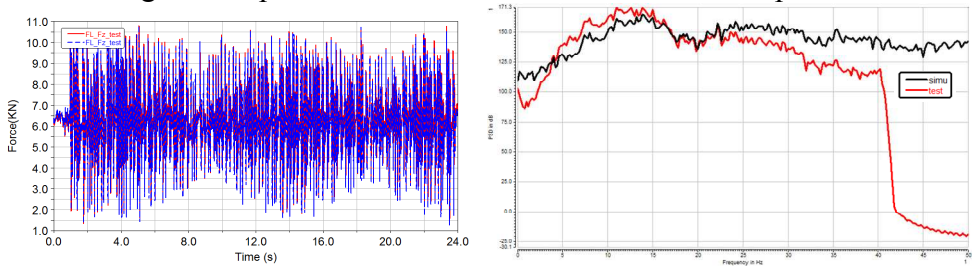
The fatigue loads prediction process has been carried on a light vehicle. The spindle vertical accelerations are regarded as the target signal that we want to reproduce and that has been measured experimentally. Also, the WFT vertical forces and the vertical accelerations at the body interface are the monitors. Take Belgian road as example, we can get the results after several iterations have been completed. Fig. 4 is the targets RMS at the every iteration.

At the last iteration, we can obtain the comparison between the experimental signals and the responses in time or frequency domain, as shown in Fig. 5, Fig. 6 and Fig. 7.



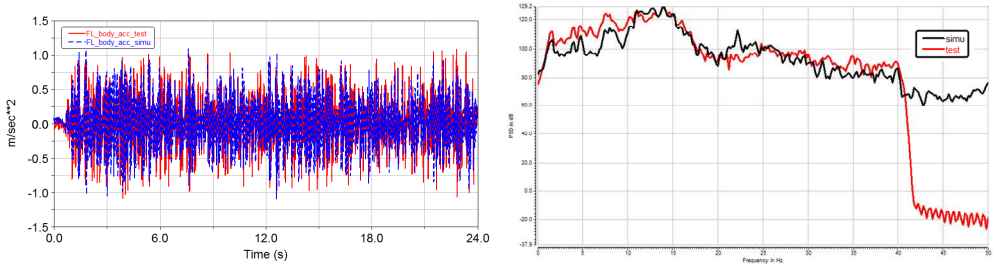
a) time domain b)frequency domain

Fig. 5 Comparison of vertical acceleration at front spindle



a) time domain b)frequency domain

Fig. 6 Comparison of vertical force at front spindle



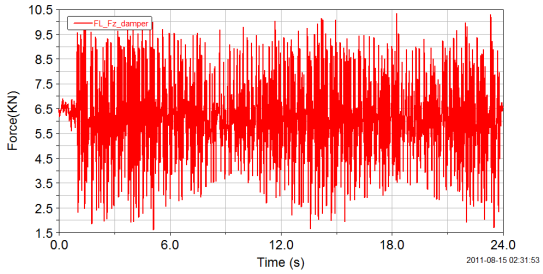
a) time domain b)frequency domain

Fig. 7 Comparison of vertical acceleration at body interface point

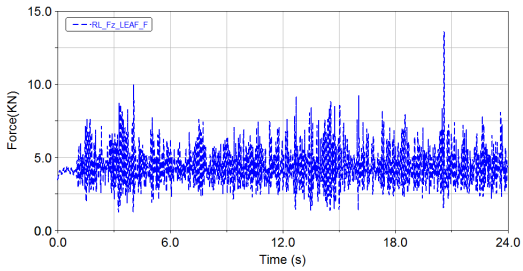
As shown in the above figures, the RMS value is acceptable. The response signals is in consistent with the experimental signals both in time and frequency domain. In particular, the vertical forces at

the spindle that is the responses of the model at the last iteration is same as the signals measured from the WFT. As a result, the experimental signals are replicated in high quality, which ensure the loads prediction accuracy.

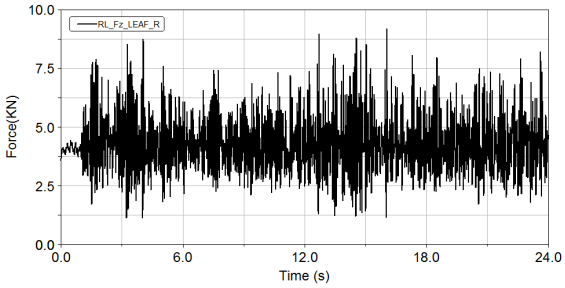
The hybrid road profiles back-calculated at the last iteration, also called the last drive signals, is used to drive the model to predict the fatigue loads at the interface points. The vertical load spectrums at some interface points are shown in Fig. 8.



a) left-front damper point



b) leafspring front point



c) leafspring rear point

Fig. 8 Vertical force signals

Summary

A procedure for fatigue loads prediction has been implemented successfully. The road test data on the proving ground multiplied by the MBS is used to back-calculate the hybrid road profile through the proposed method. The hybrid profile applied on the model can replicate the experiment targets accurately, which is validated by the comparison between the response and the target. More, the hybrid road profile that can transfer to a new vehicle for its invariability is applied to the multi-body model to obtain the body interface load.

Keywords: Data envelopment analysis; Partial least-squares regression; Outliers; Utility harmonic impedance; harmonic emission level

Abstract. A novel method is used for assessing the harmonic emission level, which is based on the partial least-squares(PLS) regression with data envelopment analysis(DEA). Based on measuring the harmonic voltage and current at the point of common coupling(PCC) and removing the inefficiency data with DEA, regression coefficients are worked out through partial least-squares algorithm. Consequently the harmonic emission level of customer is calculated.The proposed approach removes the effect of outlying data points and gets accurate estimation results. The simulation results prove that the proposed method is more effective than PLS.

Introduction

In recent years harmonic problems in power systems have been considerable increasing due to the widespread use of power electronic loads. In order to ensure good power quality, incentive-based schemes[1] were proposed to encourage the utility and the customer side to retain harmonic distortion between the limits. And the scheme must be based on determining the contribution of both sides to harmonic distortion accurately and effectively.

Various techniques have already been presented to quantify customer and utility share of harmonics at PCC. According to the IEC 61000-3-6 Technical Report, the existing approaches are mostly based on calculation of the utility harmonic impedance including invasive methods and non-invasive methods. The invasive methods[2] accurately estimate utilities and customers parameters by injecting the harmonic (or interharmonic) current to utilities or switching on (or off) any loads. These methods may be harmful to utilities. The non-invasive methods compute the utility harmonic impedance by measuring harmonic voltage and current at PCC, which mainly include the utility harmonic impedance linear regression method[3,4,5] and the fluctuation method[6]. The fluctuation method may induce big errors for evaluation results because of the harmonic parameters variation of the utility side and measurement noise. The latest linear regression method-PLS regression can model to obtain accurate results under the condition of independent variables with serious correlation.

However, the modeling data may contain some outliers in practical project. Although PLS regression has high estimation precision, the estimated results are severely affected by the presence of outliers. PLS with DEA[7] is proposed to overcome the defect. The simulation results prove that PLS with DEA is accurate and has engineering application value.

DEA model and PLS with DEA

Assume that there are n decision making units(*DMUs*)—DMU_1, DMU_2…DUM_n, each *DMU* has m types of inputs and s types of outputs

Assume $x_j=(x_{1j}, x_{2j},\ldots, x_{mj})^T$, $y_j=(y_{1j}, y_{2j}, \ldots, y_{sj})^T$, x_{ij}=the amount of the ith input to DMU_{-j}, y_{rj}=the amount of the rth output of DMU_{-j}, for $j=1, 2,\ldots,n$, $i=1, 2,\ldots, m$, and $r=1, 2,\ldots,s$. For convenience,

denote the inputs and outputs of DMU_{j0} by $x_0=x_{j0}$, $y_0=y_{j0}$, respectively. the DEA model(C^2R model) for evaluating DMU_{j0} is given by

$$\begin{cases} \max \dfrac{u^T y_0}{v^T x_0}, \\ \dfrac{u^T y_j}{v^T x_j} \le 1, \quad j = 1, 2, \cdots, \quad n, \\ v \ge 0, u \ge 0, \quad v \ne 0, u \ne 0. \end{cases} \tag{1}$$

In this model, $v=(v_1, v_2,\ldots, v_m)^T$, $u=(u_1, u_2,\ldots, u_s)^T$ are the weighting parameters for m inputs and s outputs respectively. Using Chames-Cooper transformation, the fractional programming is transferred into a linear programming problem. Let $t = \dfrac{1}{v^T x_0}, \omega = tu, \mu = tv.$ The corresponding linear rogramming problem of C^2R model and its dual programming are

$$\left(P_{C^2R}\right)\begin{cases} \max \mu^T y_0 = h_0, \\ \omega^T x_j - \mu^T y_j \ge 0, j = 1,2,...,n, \\ \omega^T x_0 = 1, \\ \omega \ge 0, \mu \ge 0. \end{cases} \tag{2}$$

$$\left(D_{C^2R}\right)\begin{cases} \min \theta. \\ \sum_{j=1}^{n} x_j \lambda_j \le \theta x_0, \\ \sum_{j=1}^{n} x_j \lambda_j \ge y_0, \\ \lambda_j \ge 0, j = 1,2,...,n. \end{cases} \tag{3}$$

Definition 1. If $\left(P_{C^2R}\right)$ has optimal objective value $h^0=1$, then DMU_{j0} is called weak DEA efficient h^0 is called efficiency index.

Definition 2. If $\left(P_{C^2R}\right)$ has an optimal solution $\left(\omega^0, \mu^0\right)$ such that $\omega^0>0$, $\mu^0>0$ and $\mu^0 y_0 = 1$, then DMU_{j0} is called DEA efficient.

The optimized PLS with DEA can detect the disturbed data and obtain accurate estimation results with right model. Analysis and modeling steps are as follows:

1) According to the theory of DEA and the C^2R model, it is convenient to evaluate the measured harmonic voltage and current information and remove the inefficiency data. Regression coefficients are worked out through PLS algorithm with the remained data.

2) Extract principal component t_1, $t_2,\ldots,t_r$ on the basis of independent and dependent variable matrix E_0 and F_0(centered and normalize). Determine the number of principal components with cross validation analysis.

3) Obtain the regression equation. According to Eq. (4) and the relationship between the principal component and independent variable, the regression equation of y and x are calculated.

$$\begin{cases} E_0 = t_1 \alpha_1^T + \cdots + t_r \alpha_r^T + E_r \\ F_0 = t_1 \beta_1^T + \cdots t_r \beta_r^T + F_r. \end{cases} \tag{4}$$

Harmonic Source detection Principle

In the IEC Techical Report 61000-3-6, the harmonic emission level is defined as the magnitude of the harmonic voltage vector at each harmonic frequency, which is caused by the considered installation at the point of evaluation.

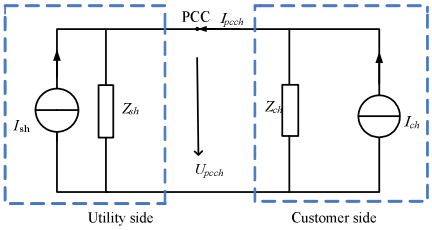

Fig.1 Harmonic source detection model

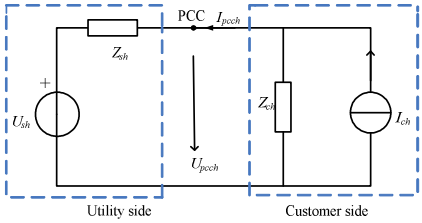

Fig.2 Thevenin-Norton model

In Fig.1, the disturbance sources are the customer harmonic source I_{ch} and the utility harmonic source I_{sh}; Z_{ch} and Z_{sh} are the harmonic impedances of the respective systems. The current phasor I_{pcch} and voltage phasor U_{pcch} are measured at PCC. According to Fig.1, Eq.5 and Eq.6 are obtained, where $U_{pcch\text{-}pre}$ and $U_{pcch\text{-}post}$ present the harmonic voltage at PCC before and after the customer is connected to the network.

$$U_{pcch\text{-}pre} = I_{sh} Z_{sh} \tag{5}$$

$$U_{pcch\text{-}post} = I_{sh} Z_{sh} + I_{pcch} Z_{sh} \tag{6}$$

The custom harmonic emission level E_{ch} can be calculated by subtracting Eq.5 from Eq.6.

$$E_{ch} = I_{pcch} Z_{sh} \tag{7}$$

According to Eq.7, system harmonic impedance calculation is the key to the harmonic emission responsibilities of utility and customer. PLS regression with DEA is presented to estimate the system harmonic impedance in this paper. Thevenin-Norton model is presented in Fig.2 to establish the regression model and Eq.8 and Eq.9 are obtained.

$$U_{shx} = U_{pccx} - I_{pccx} Z_{shx} + I_{pccy} Z_{shy} \tag{8}$$

$$U_{shy} = U_{pccy} - I_{pccx} Z_{shy} - I_{pccy} Z_{shx} \tag{9}$$

Regression coefficients U_{shx}, U_{shy}, Z_{shx}, Z_{shy} are worked out through PLS regression with DEA. Then the customer harmonic emission levels can be obtained by Eq.7.

Computer Simulation

The computer simulation based on the harmonic source detection model evaluates the *h*th harmonic voltage emission level using the software Matlab/Simulink, where $\dot{U}_{sh} = 50\angle 51^\circ$ V, $\dot{I}_{ch} = 6.36\angle 45^\circ$ A, the mean value of Z_{sh} and Z_{ch} are 15+j30 Ω and 25+j300 Ω respectively.

The harmonic voltage and current data measured at PCC are shown in Fig.3, which has 500 sample points.

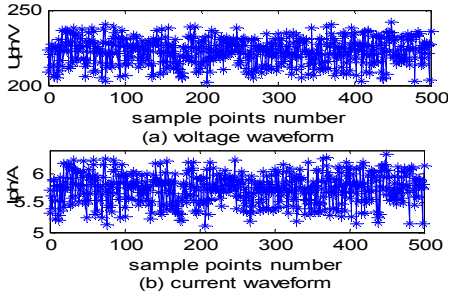

Fig.3 Magnitude waveforms of *h*-th current at PCC

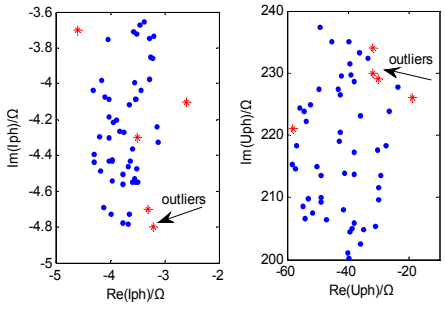

Fig.4 50 sample points of voltage and current at PCC and five outliers

The results of the Z_{sh} are estimated in three different cases(50 sample points as a subinterval). In case 1, the estimation results are computed based on PLS regression. In case 2 and 3, five outliers are

added in every 50 sample voltage and current points artificially. As shown in Fig.4, it is difficult to remove the outliers directly. The results of the Z_{sh} are estimated based on PLS and PLS with DEA, respectively. The results in three cases are shown in Table 1.

Tab.1 Comparison of errors of Z_{sh} in three cases

	Reference Value	Case 1	Case 2	Case 3
Error of Z_{shx}/%	15	0.847	19.98	1.133
Error of Z_{shy}/%	30	0.458	10.8	1.177

The relative errors of Z_{shx} and Z_{shy} estimated in case1,case2 and case 3 are shown in Table 1. From Table 1, we can see the estimation errors in case 2 are about ten times in case 1 and case 3. Estimation errors in case 1 and case 3 are both small. In comparison with the errors of the Z_{sh}, it demonstrates that PLS with DEA can get more precise results than PLS when modeling data contain outliers.

According to Eq.7, the customer harmonic emission level is 193.24V, about 87.01% of the harmonic voltage at PCC. The assessment result agreed in the theoretical calculation result indicates that the proposed method is valid.

Conclusion

This paper presents a new approach to evaluate the harmonic emission level of the utility and customer side, which is based on partial least-squares regression with data envelopment analysis. Due to the power system fluctuation or measurement error, the modeling data may contain some outliers. And PLS regression is very sensitive to abnormal data. This method retains the advantages of PLS and avoids the effect of erroneous data. The laboratory results indicate that the proposed method is effective and accurate.

Keywords: Micromouse Maze dash motion command

Abstract. Micromouse is a small autonomous robot, which must navigate itself through an unknown maze from the start to the destination, the main challenge for micromouse is to solve the maze and find the optimum path. Detailed design of best-path finder was given. According to the different dash mode combination, dash path of micromouse in complex maze was analyzed. Motion command generator is developed to generate list of the motion commands in order to guide the robot dash from the start to its destination.

Introduction

For micromouse system, it is mainly controlled by a microcontroller (MCU) and a field-programmable gate array (FPGA). All of the calculations and decision makings will be executed by the MCU and the FPGA will handle the pulse-width modulation (PWM) and I/Os address mapping. Besides that, the system also has 6 pairs of infrared sensors for the obstacle detection[1-4].

Micromouse is able to navigate through an unknown maze in search for a faster path from the start to the finish point[5-8].The maze is configured by placing walls along the grid-points formed by multiples of 18cm square, the squares are arranged in a 16 x 16 row-column matrix, as shown in figure 1.

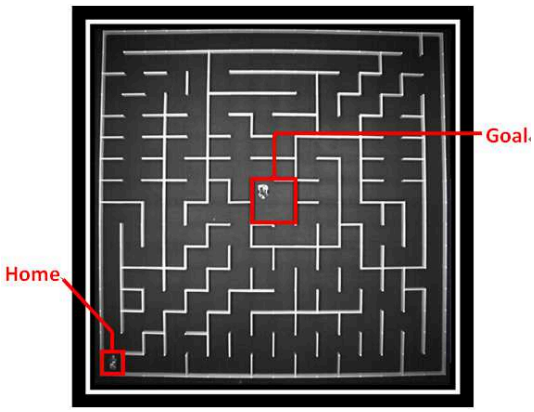

Fig.1 Mouse and maze

The main funciton for micromouse travelling in the maze under the help of sensors, then find the whole information of the maze, then the robot has to solve the maze and find the best path from home to desitnation, then micromouse dashes to destination according the best path in the shortest possible time.

Best-path finder (BPF)

After searching the maze, a best-path dinder is developed to determine the shortest path for the robot to run from the current position to the nearest goal.

Best-path finder will analysis the 4 cells of goal and mark the one with the smallest solving step number as the final destination for the future routing purpose. Then the best-path finder will start the checking from that goal back to the ‘current’ position. The finder will store the position of the cells in

the ‘best’ route into a special memory list. The finder will determine which the next suitable cell is by checking the solving step number in its surrounding cells. If there are few surrounding cells containing the same number, it will choose the cell in the same direction from the previous cell.

Fig.2 Maze solve

The graph shows that there are three surrounding cells containing the solving step number of 21, so the Best-Path finder will have to choose which one is the most suitable cell for it to form the most optimal route. Since the previous cell of 23 is on the ‘north’ side of the cell, so the finder should choose the cell of 21 on the ‘south’ side in order to form a straight path to save the travelling time as running a straight path will spend less time than making few turns.

Figure 3 shows the flowchart of best-path finder.

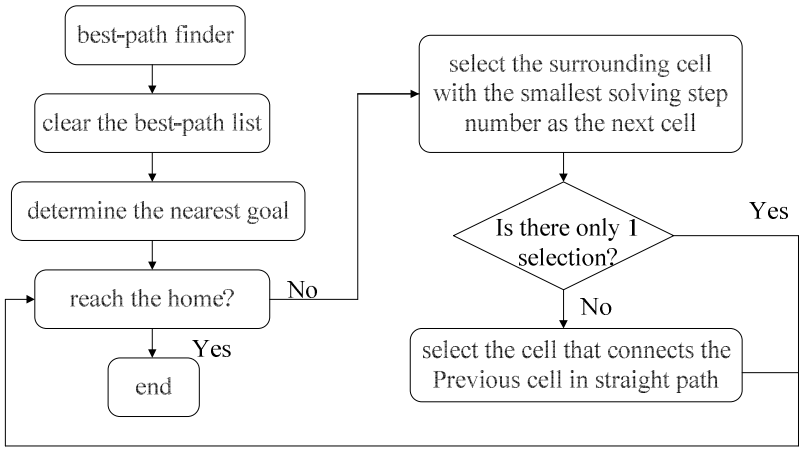

Fig.3 The flowchart of best-path finder

Dash mode

In general, micromouse dashes along the straight dash, or make a 90 degree left or right turn, but in special circumstances, the mouse will dash into below maze as shwon in , in order to save time, the best way is dahing along diagonal path, as shown in fiugue 4.

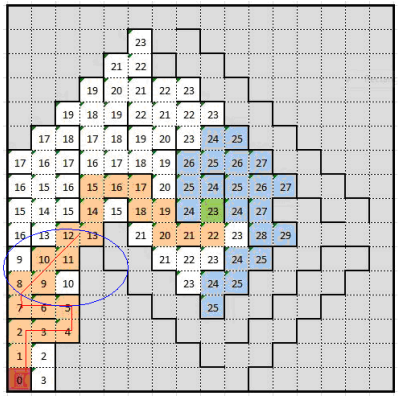

Fig.4 Maze for dash in diagonal

According to the different dash combination, dash mode of micromouse in complex maze as shown in figure 5.

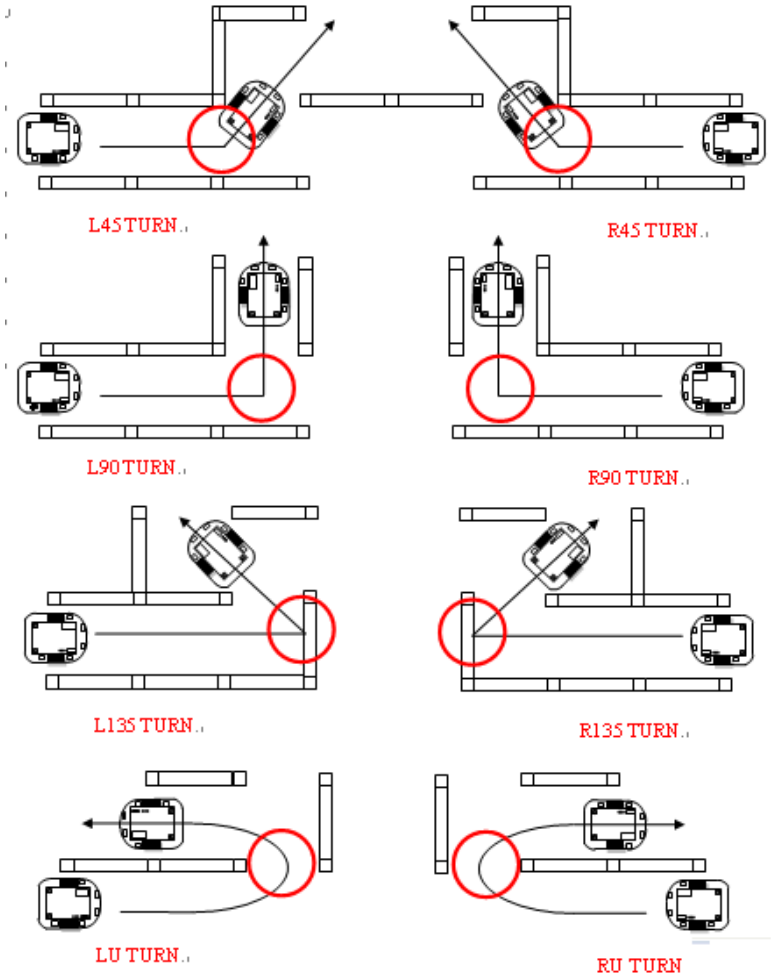

Fig.5 Normal dtraight-diagonal dash

Motion command generator (MCG)

After analysis the possible dash path of micromouse , a motion command generator is developed to generate another list of the motion commands in order to guide the robot dash from the start to its destination.

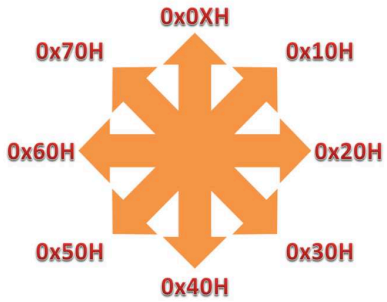

Fig.6 The Star chart of motion direction

The graph above shows the relation between robot's directions and motion commands. The robot will move forward or turn left or right according to the motion command. A motion command is an 8-bit data and can be represented as two digits in hexadecimal format which can be from 0x00 to 0xFF.

The first digit is used to represent the moving direction while the second digit represents the number of blocks that the robot is going to move for. So if the robot is going to move forward for X blocks, then the command will be 0X in hexadecimal format. If the command is 0x60H, then the robot will try to perform a left turn.

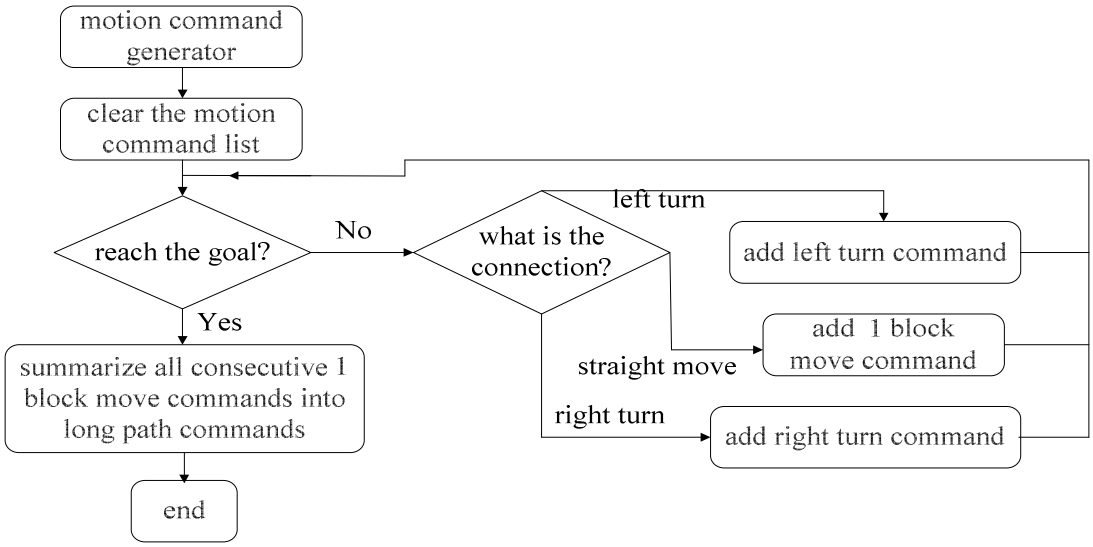

Fig.7 The flowchart of Motion Command Generator for dash

Summary

One of main challenges for micromouse is to solve the maze after searching and find the optimum path. Detailed design of best-path finder based on flood-fill was given. According to the different dash mode combination, dash path of micromouse in complex maze was analyzed. Motion command generator is developed to generate list of the motion commands.

Double DSP communication based on CAN Bus Interface

Hongde DENG [1, a], Zhian YAN [2, b]

[1,2]Science and Technology on UAV Laboratory, Northwestern Polytechnical University, Xi'an 710065, China

[a]email: denghongde@126.com, [b]email:zhian.yan@163.com

Keywords: DSP communication; CAN bus; double buffer

Abstract: In view of the problems on communication in double DSP systems, various communication methods are compared and advantages of CAN bus are also presented. This paper introduces hardware and software of communication using with CAN bus in DSP systems. The registers configuration of CAN is described in particular. Data are received by interrupt and stored double buffer. The scheme has been applied in a UAV flight control system which performs very

Introduction

Digital signal processor（DSP）plays an important role in industrial control because of its ample command systems, high-speed and high-precision computing ability, as well as its various peripherals. The C2000 serial DSPs of TI are widely used. With the increasing computing complexity and real time requirement, the single DSP can't provide the required peripheral interfaces and computing capacity, so multiple DSPs system is needed [1].

This scheme is designed to complete the communication between the double DPSs of a small UAV flight control system. In this system, one TMS320F28335(28335)DSP（DSP A）is in charge of attitude and navigation computations through collecting data from sensors including the angular rate gyroscopes, accelerometers, magnetometers and GPS; the other DSP（DSP B）is in charge of flight control and missions execution. These two DSPs should transfer 80 bytes to each other in 5ms, this requires the reliable and real time communication between these two DSPs.

1. DSP communication schemes compare

Generally, there are three interlink architectures among DSPs: parallel, serial and integrated operations. In parallel operation, CPU should support the parallel operation or public memory which is not included in C2000 serial DSPs [2]. In serial operation, the CPUs can communicate through DSP serial port, DMA channel, dual-port RAM, FIFO, or public memory. Using DSP serial port and DMA channel is convenient because they are integrated in DSP chip. But using dual-port RAM, FIFO or public memory is not so easy because they usually need to be expanded by operator and need extra hardware support.

The following serial peripherals can be used for DSP communication: SCI, SPI，I2C，CAN and McBSp. As TMS320F28335 for example, table 1 compared the performance among these peripherals, and shadow part s mean the highest performance.

The primary difficulties when using these peripherals: SPI interface could receive pseudo data; SCI data length is 8-bit, but DSP is a 16-bit system, so the high 8-bit data received are invalid. McBSP is the peripheral with highest speed, but the interfaces and software used are too complex. Through comparing, CAN module has the following advantages: 32 mailboxes of 32-bit data length for storing data; transferring data with strong anti-jamming capability and the biggest rate 1Mb/s only using 2 data wires. Most important, two CAN module interfaces can transmit or receive data simultaneously without considering the conflicts, and the program used is simple. So choosing CAN module is the most ideal communication scheme for small data exchange.

Table 1 Performance compare of peripherals

	SPI	SCI	I^2C	CAN	McBSP
Rate b/s	SYS[1]/4	SYS/16	400k	1M	>50M
FIFO level	16	16	16	32 mail-boxes	16
Data length	16	8	16	32	32
Interface number	1	3	1	2	1
Wire number	4	3	2	2	6
Anti-jamming	medium	medium	medium	strong	medium
Complex degree	medium	medium	simple	simple	complex

Note: 1. SYS means the system low-speed peripheral clock frequency

2. Hardware design of CAN communication interface

The CAN controller integrated in TMS320F28335 is a 32-bit peripheral module. This module is compatible with CAN2.0B agreement and provides 32 message mailboxes of 8−byte data length, a 29−bit identifier, and several control bits. The module also has the following features: programmable wake-up on bus activity, automatic reply to a remote request message, automatic retransmission of a frame in case of loss or error and self-test functions [3] [4].

Although CAN controller is integrated in DSP, the serial communication signal of DSP is not compatible with the standard CAN bus agreement, and after testing, simply connecting the TX and RX between two DSP CAN modules is not working. The signal must be converted to the standard CAN bus data through driver chip, then the two CAN modules can communicate properly.

The hardware design of CAN communication interface is shown in figure 1 (at the end of this paper). In this design, the driver chip SN65HVD230 from TI company is used. In order to match bus impedance, the resistances of 120Ω （R1 and R4）are added to the both ends of bus to improve the anti-jamming and reliability of data communication.

Although the mailbox of DSP eCAN module can be configured as a receive or send mailbox, and using the advantage of two eCAN modules in each DSP, this scheme configures one eCAN module as the receive module responsible for receiving data only and the other as the send module responsible for sending data only. This design can guarantee reliability and real time performance of the flight control system as well as support follow-up big data transfer.

3.Software design of CAN communication interface

The software design includes four parts: initialization module, mailbox configuration module, transmitting data module and receiving data module. Only 32-bit accesses are allowed to the eCAN module registers and these registers must be configured through defining shadow registers. As the mailbox enable register for example, the shadow register must be defined first before enabling some mailbox. For example, we can set Struct ECAN_REGS ECanaShadow as following:

```
ECanaShadow.CANME.all=ECanaRegs.CANME.all;
  ECanaShadow.CANME.bit.ME0 = 1;//enable mailbox 0
ECanaRegs.CANME.all=ECanaShadow.CANME.all;
```

Only through the above method, can the values of bits in the ECanRegs be setted properly. To be simple, in the following text, this step is omitted in all eCAN register setting.

3.1 Initialization module

Initialization must be done before using CAN module, including setting bit timing configuration register and communication baud rate, resetting mailbox control register and state register. The initialization process is shown in figure 2.

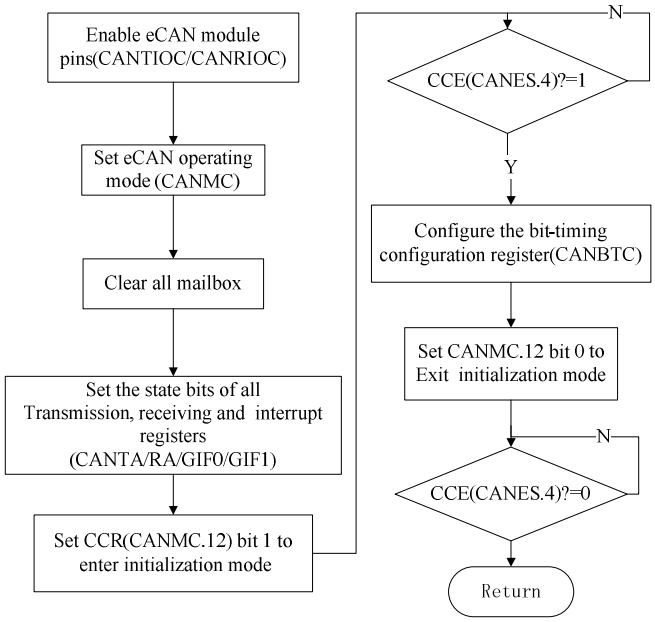

Figure 2 eCAN module initialization

Every step in the above process lists the name of register which should be configured. This process can refer to the TI document DSP2833x_ECan.c. This system sets CAN module operating in eCAN mode, mailboxes 16 to 31 can be used and the communication baud rate is 1Mbps.

3.2 Mailbox configuration module

This module is used primarily to set the mailbox function (transmitting or receiving), mailbox identifier and interrupts. Mailbox function is defined by the register CANMD: the value 0 means that this mailbox is defined as a transmit mailbox, the value 1 as a receive mailbox. For example, this setting CANMD.bit.MD0=0 means that mailbox 0 is defined as a transmit mailbox. 40 bytes should be transferred in 5 ms and each mailbox can store 4 bytes, so 10 mailboxes are needed for each transmitting and receiving module.

We configure the mailboxes eCANA0~9 as transmitting mailboxes and eCANB0~9 as receiving mailboxes. Registers MSGID and MSGCTRL determine the mailbox parameters [5]. To insure the real time performance in receiving data, the receive mailbox receives data in interrupt mode.

3.3 Receiving data module

The data is received in interrupt mode. In order to generate interrupt again, ISR needs to save the data received and clear the interrupt flag bit. This scheme uses double-buffer to make sure the data is received and saved correctly. The two buffers are uint64 cell array with 20 bytes data length. Each buffer can store 40 bytes data from mailboxes 0~9. The cycle of the interrupt received is determined by the transmitting cycle, and the cycle 5ms is defined in this design.

3.4 Transmitting data module

To start a transmission is simple. Just write the message data into the mailbox data field MDH and MDL, then set the corresponding flag in the transmit request register to start the transmission of the message. If the message is sent successfully, transmit-acknowledge flag of the corresponding

mailbox is set to 1. Generally, before next step, we should wait transmit-acknowledge flag is set. But if the data can't be transmitted successfully, the program will fall into infinite loop. To avoid this, we wait a little while after transmit-acknowledge flag is set. This design waits for 640us after transmitting 80 bytes with baud rate 1Mbps.

4. Conclusion

The scheme has been applied in a UAV double DSP flight control system for exchanging data and commands. After testing, this system performs very well. The CAN bus communication method between two DSPs introduced in this paper can also be used for communication between DSP and other system.

Keywords: Aerospace Test and Launch Process; Dynamic Management System; Network Di agram Method; Optimization.

Abstract. To manage and optimize aerospace test and launch process in real time and dynamically, the aerospace test and launch process dynamic management system based on network diagram method has been designed in this paper. Firstly, we summarize the research status of test process optimization in references to find the shortages in optimization and management. Secondly, we design the system from three aspects including the process design, data management and indexes evaluation, respectively. Subsequently, the software is introduced briefly. Finally, the deficiencies of the system and improvement goal are put forwarded.

0 Introduction

In order to guarantee the normal function, the good performance, safety, and on-time launch, comprehensive and integrated test and evaluation of the rockets before launch is necessary. At present, the optimization of the test process mainly finished by the department of aerospace industry and engineering, technical personnel in launching site. Because of their long-term engineering practice accumulated, they concentrate on quality assurance and technical feasibility to simplify test project or compress test process. In addition, the systemic theory and method has not been formed.

Therefore, increasing the test's effectiveness, optimizing test process fundamentally, and shortening the test time really effectively can adapt China's space launch to distance test and control, and high density launch mission.

1 Demand Analysis

1.1 Research Status of Test Process Optimization and the Enlightenment

Aiming at the insufficiencies of test process, there are a lot of references optimize it. For instance, reference [2] analyzed that the constraints to shorten the test time are the reliability of the components, single, system and the rockets' bus structure problems. Reference [3] presents two kinds of ideas of spacecraft test process reengineering. The first one is the optimization and improvement for the current model and the second one is the process reengineering pattern. Reference [4] is in the light of the problem of launch site test process reengineering, some basic conceptions were put forwarded. Reference [5] optimizes the test process using the process optimization matrix.

In space launch task, it is necessary to establish task flow chart. While using computer software system instead of artificial hand is a wise choice. Not only because it can save a lot of manpower, material and financial resources, but also to facilitate partial adjustment for flow chart in real-time without affecting the whole process, so as to achieve the purpose of optimizing the process. Therefore, it is necessary to design and develop a software system which is dedicated to draw flow chart of aerospace test and launch. This paper tries to build a software system, manage the establishment and optimization of process in a real-time dynamic way.

1.2 Research Ideas and Methods

This article plans to study from the following three aspects. First one is the design of the process. We choose network diagram method to design the test and launch process. Second one is the data management. We use SQL SERVER 2005 database system as data support. Besides, we use Microsoft Visual Studio as the programming environment to develop the software. The third one is the process index evaluation. There are many evaluation methods. Improved analytic hierarchy process which is the combination of qualitative and quantitative analysis is used to evaluate the process scheme.

2 Integrated Technical Program

2.1 System Functions and Composition

Aerospace Test and Launch Process Dynamic Management System can make optimization design for the different test and launch processes of the Aerospace task. Moreover, it can take effective management of each project node in the test launch processes. According to the input and constraints, use the process configuration and evaluation algorithms, it can make comprehensive evaluation of the implementation effect of the various stages of the mission. In this way it can provide related business personnel training support for the task processes design, optimization and dynamic configuration. The main functions are as follows.

Table 1 Functions of the Process Dynamic Management System

System functions	Details
1. Design and display of the Process	multiple process designs in once test mission, display each process, task node and the relationship of them graphically
2. Management of the task nodes	display and edit various input conditions and constraint information of each node, including task name, node name, key equipment information and ,etc.
3. Dynamic configuration of task nodes	dynamically configure the input and output parameters and constraints which can synchronized with the actual work tasks
4. Assess of the process and task node	Real-time assessment of the current task node is allowed in the task implementation process to provide guidance for the next phase of task orientation.
5. Data and Information Management	To store tasks, equipments, processes, task nodes, etc. Application software can read the previous task processes information and do graphical reduction

Aerospace Test and Launch Process Dynamic Management System is made of the following four parts:

(1) Application Files: HTCPM；

(2) Application Extension Files: KERNEL32.DLL, MFC42D.DLL, MFCO42D.DLL, MSVCRTD.DLL；

(3) Access Database File: HTCPMDB；

(4) Custom Document Library Files.

3 The System Software

To make the development of the Aerospace testing and launching Process Dynamic Management System(A), we first to consider about the implementation and integration of software functions, then optimize the interactive and practicality of the interface. We use Microsoft Visual Studio as the programming environment, and the SQL SERVER 2005 database system as data support. System software includes three modules, named Process Design and Configuration, Process Database Management and Evaluation of the Process indexes, respectively.

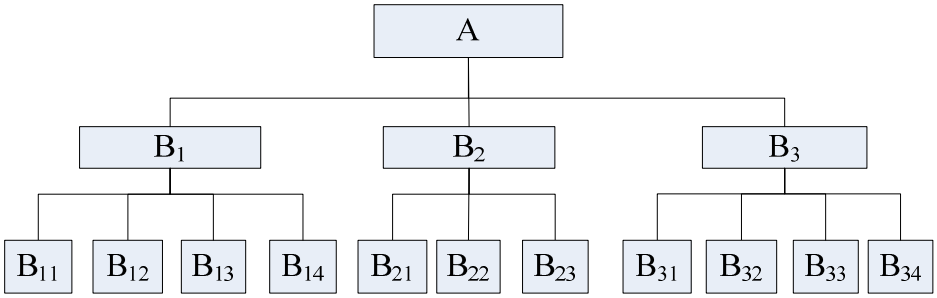

Figure 1 System Software Composition

Process Design and Configuration (B_1): Display and edit various input conditions and constraint information of each task node in the process, including the task model, the task name, job name, job content, time consumption, energy resource consumption, reliability, the device key information, the priority, importance, and operating direction and so on. Nodes can be combined edit to complete multiple process designs in once test mission. The multiple processes including four modules, which are the Flowchart Element Editing Module (B_{11}), the Process Document Management Module (B_{12}), the Process Parameter Calculation Module (B_{13}) and the Process Output Module (B_{14}), respectively.

Process Database Management (B_2): Relational database table format are included to store and manage tasks, equipment, project node and other information. Process file format is formulated and file storage of the process information is achieved. Reading the previous stored process files to restore files and graphical reduction is supported, which is ease of analysis, comparison and printing output. Good interactively method can be considered and utilized to graphically edit and display each process, task node and the relationship of them which help to the comparative analysis. Include the Process Import and Export Modules(B_{21}), the Process Query Module (B_{22}) and the Process Relations Display Module (B_{23}).

Evaluation of the Process Indexes (B_3): Main to complete the evaluation of the node or the whole process in one project, provide guidance for the next phase of task orientation. Four modules named the Evaluation Index Management Module (B_{31}), the Expert Information Management Module (B_{32}), the Assess Event Management Module (B_{33}) and the Assessment Calculation Module (B_{34}) are included.

4 Conclusion

Design of aerospace test and launch process dynamic management system not only improves the efficiency of the flow chart drawing and facilitate adjustment and improvement, but also provides important technical means for process optimization. However, the system we proposed still exist some shortcomings. In the future system operation interface can be enriched to make the operation easier. In addition, in the future real time optimization based on personnel, equipment, the weather element can be increased for key nodes, so that the optimization of the process is not only limited to the optimization based on time.

Research to the Development of Network-anticipated Controlled System based on Arbitrary Bounded Packet Loss

LIU Guanqun[1, a]

[1]HuNan Radio&TV University, Changsha 410004,China

[a]LIUGuanqun05@yeah.net

Keywords: Networked Control Systems; Packet Loss；Linear Matrix; BP Neural Network

Abstract. In recent years, due to the rapid development of computer technology and the expanding of its controlling scale, people pay more and more attention to the study of network control system. Network control system is closed loop control system connecting the communication network connect sensor, controller, actuator etc. At the same time, the introduction of the communication network control system brings a lot of problems, such as data transmission delay, network packet loss and so on, which make the analysis of the network control system become very complicated. This paper analyzes background of the topic, significance and research status, and review the network control system.

1. Description of the network control system

Normally we does not consider network, thinking actuators, controlled object and sensors are together. The three objects can be seen as discrete time system. Between sensor and controller, the controller and actuators it is the network connection, which form a closed loop control. Sometimes in order to study it conveniently, we consider only one of the networks. [1]The traditional control problem considers system itself has a disturbance, parameter uncertainty and so on. After network's join the state can not reach to or can not completely reach to the controller. In the case of this kind of random, we have to study other control problem including the stability of the system and its performance. Network control system structure diagram is shown in figure 1.

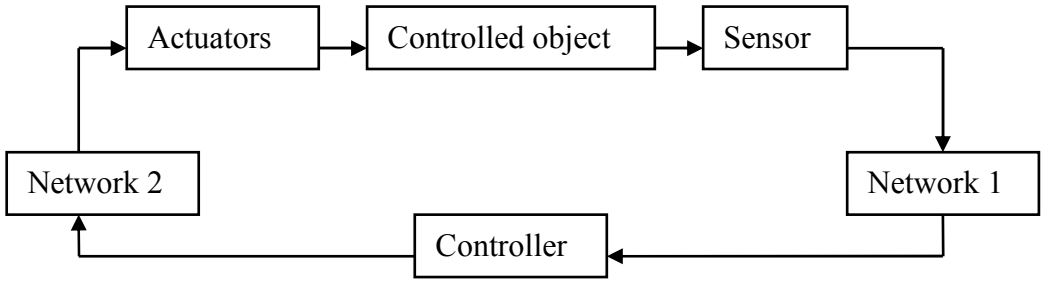

Fig1. The Configuration of the Networked Control System

1.1 Network structure

Topology structure of control network must be able to make each network node in networked control systems (such as sensors, controllers and actuators, etc.) easy to interconnect, and save connection as much as possible and easy to maintain. [2] This structure must be able to assign the system processing function and calculate load to as many smaller computational network unit as possible. In the central control system, once a single controller node fails, the system will be paralyzed; in contrast, network control system of the control network must be able to implement multiple distributed controls, the controller node so as to enhance the system robustness.

1.2 Network communication protocol

According to the different levels of network application, currently a variety of communication protocols has been put forward; these protocols are mostly follow seven layer open system interface of ISO standards issued by the OSI.

Considering the particularity of control network, the communication protocol used in the control network is not necessarily in accordance with the standard of the seven layer model.

1.3 Network performance

Performance indicators of a network system about evaluation of whether to meet the demand of real-time control mainly include: Access latency, Transmission Time, Response Time, Message Collision, Message Throughput, Packet Size, network utilization, and some other certain industry, etc. For control system, the ideal control network must satisfy at least the following two principles: bounded delay and guaranteed transmission. [3]That is to say, in the control of network information there have to achieve success in bounded time of transmission. Unsuccessful information transmission or too-long transmission delay may degrade the performance of the network control system, and even destroy its stability.

2. Packet loss characteristic of network control system

There are always many data transmits at the same time, it may lead to collision between different data transmission, or an individual node failure in competition, as a result, packet loss born. In order to avoid the happening of this kind of situation, a lot of network has set retransmission mechanism, but due to being influenced by time, retransmission may fail, resulting in the loss of packets. However, not network packet loss will cause the loss of system stability, instead as long as in a certain range, the system remains stable. Therefore, the effect of data packet loss on the stability of the system is still an issue.

2.1 Analysis of packet loss in NCS

In national communicative system, the packet loss mainly includes the passive and active packet loss. Active packet loss refers to the measures network control system take in order to achieve a certain purpose. [4] Passive packet loss is caused by data communication mechanism and network bandwidth restrictions. In this case, the packet loss is harmful for the performance of networked control systems.

At present, three methods are commonly used to describe the data packets lost. The first one is statistical method, as well as the probability distribution of the data packet; the second one is the total amount of packet loss, the last one is to see it as the connection channel. It will have a packet loss of replication as dynamic switch system.

2.2 Impact of packet loss on the stability of the system

Usually, in the process of study, we separately consider the network induced delay and packet loss. Due to the unreliability of the network transmission path, in the process of transmission, it may lead to transmission delay, even the packet loss.

An asynchronous dynamic system structure is shown in figure 2.

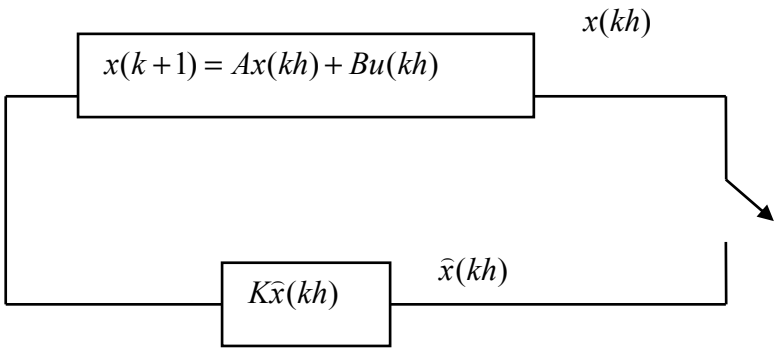

Fig.2 Structure of asynchronous dynamical system

A dynamic characteristic of system is as follows:

$$\begin{cases} S_1 = \hat{x}(kT) = x(kT) \\ S_2 = \hat{x}(kT) = x((k-1)T) \end{cases} \tag{1}$$

If the system's augmented matrix is $z(kT) = \left[x^T(kT), \hat{x}^T(kT)\right]^T$, then closed loop system of the network with the existence of packet loss can be expressed as the following type:

$$z((k+1)T) = A_i z(kT), i = 1,2 \tag{2}$$

When the switch is in position 1, $A_1 = \begin{bmatrix} A & BK \\ 0 & BK \end{bmatrix}$, when the switch is in position 2, $A_2 = \begin{bmatrix} A & BK \\ 0 & I \end{bmatrix}$.

Usually, in the case of a certain packet loss the network control system still can guarantee the stability of the system. In this case, the inferences were as follows:

Corollary 3.1: suppose closure rate of system switch r. If exists Lyapunov function $v(x(kT)) = x^T(kT)Px(kT)$ and scalar factor α_1 and α_2 alpha in the system that satisfy the following conditions: $\alpha_1^r \alpha_2^{1-r} > 1$, $A_1^T P A_1 \le \alpha_1^{-2}$, $A_2^T P A_2 \le \alpha_2^{-2} P$, then the index of the closed-loop system is asymptotically stable.

Theorem 3.1: if the open-loop system is critical stable, so for $0 < r \le 1$, the index of the closed-loop system is asymptotically stable. If open loop system is not stable, then for $r_x < r \le 1$, the index of the closed-loop system is asymptotically stable.

$$r_x = \frac{1}{1 - r_1 / r_2} r_1 = \log[\lambda_{\max}^2 (A + BK)], \lambda_2 = \log[\lambda_{\max}^2 (A)] \tag{3}$$

3. Generalized prediction principle

With the development and application of MAC and DMC, Clarke and some others put forward Generalized Predictive Control (GPC) based on the parameter model of in 1984. This algorithm's controlled object model uses CARIMA model introduces the multi-step optimization performance index on the basis of generalized minimum variance Control, which can effectively overcome the influence of random disturbance and random noise.

3.1 Object model

Different from MAC, the GPC adopted minimized model. [5]It takes discrete difference equation with step non-stationary random noise disturbance to describe the generalized predictive control of the controlled object:

$$A(z^{-1}) y(k) = B(z^{-1}) u(k-1) + C(z^{-1}) \xi(k) / \Delta \tag{4}$$

Multiply both sides respectively by the difference operator Δ:

$$\overline{A}(z^{-1}) y(k) = B(z^{-1}) \Delta u(k-1) + C(z^{-1}) \xi(k) \tag{5}$$

In the type, $\overline{A}(z^{-1}) = A(z^{-1})\Delta = 1 + \sum_{i=1}^{n_\alpha + 1} \overline{a}_i z^{-i}$

By the two types, we can see that through mathematical processing, the mathematical model of controlled object has become the system with control increment and integral action and stationary random noise. Unlike previous CARMA model, this model is called the Controlled Auto-Regressive Integrated Moving-Average), namely the CARIMA model.

Summary

Aiming at the networked control systems with arbitrary bounded lost package, this paper proposes a feasible guarantee, network predictive controller design method of a smaller amount of calculation. Extended state space model is used to describe the network control system; the condition of using state feedback controller of the system stability was obtained. Through endless time domain control parameters into a free control function and a state feedback control law, satisfied the system state constraints and input constraint network predictive controller.

Keywords: feed-forward control, rolling force fluctuations, feed-forward adjustment amount, regulatory agencies, neural networks

Abstract. The influence on the shape of the strip from rolling force fluctuations has been analyzed. The combination of intermediate roll bending and work roll bending has been adopted. The principle of rolling force feed-forward control has been analyzed. The feed-forward control model has been established on the basis of neural networks. The model has been successfully applied to a rolling mill and a good effect has been achieved.

Introduction

Plate-shaped automatic detection and automatic control board is the only way to improve the quality level of the strip shape[1]. Theoretical research and production have proved that incoming steel crown with volatility is one of the largest factors affecting the quality of the finished strip shape, especially in the lead with the tail section[2]. In tandem cold mill flatness control, rack control to achieve zero bias alone is difficult. The steel profiles according to the principle of equal proportions of crown should be adopted to control flatness. If the front of the rack plate shape can be controlled, finished rack can be easier to good quality control strip shape. In the study of cold tandem rolling unit, cold rolling mill plate-shaped feed-forward control method has been developed on the basis of neural networks. Existing automatic flatness control model has been improved and feed-forward control strip between the plate-shaped rack has been achieved in the front plate-shaped feed-forward control link. The disadvantage of the closed-loop feedback control has been remedied. The shape control accuracy has been increased further. In cold rolling process, rolling force fluctuations shapes a deep impact on flatness. The combination of work roll bending and intermediate roll bending is adopted in feed-forward control.

Impact on flatness from rolling force fluctuation

Rolling force is affected by many factors, such as the geometric characteristics of the strip[3], the deformation resistance, friction coefficient, the roller diameter reduction, rolling speed, the tensile stress distribution and so on. In the rolling process, not only incoming thickness and hardness of the crown will change, but also friction coefficient, the rolling speed and the tension will change, which can lead to rolling force constantly changing during the rolling process. The rolling force variation caused elastic deformation of the roll change. Load roll gap shape changes, and ultimately the strip shape is affected.

Regulatory agencies of feed-forward control

The impact of hydraulic bending on exports strip thickness is small[4]. Since the control response time of hydraulic bending roller and hydraulic pressure are similar, the bending force is adopted to compensate for changes in the rolling force. The shape feed-forward control strategy is essentially to compensate rolling force. Compared with closed loop control system, there is no hysteretic problem. So it is called feed-forward control. According to shape control efficiency coefficient, influence on the shape of the rolling force is similar with bending control. The bending rolling force control is adopted to offset the impact of fluctuations on the plate-shaped.

Principle of feed-forward control

The front plate-shaped overall compensation principle feed-forward control is to compensate impact on flatness from rolling force changes. The rolling force per unit width change amount is adopted to solve corresponding bending force compensation amount:

$$\Delta F_{\mathrm{W}} = \zeta \cdot \frac{\Delta P}{W} \tag{1}$$

$$\zeta = -\frac{K_{\mathrm{PB}}}{K_{\mathrm{FW}}} \tag{2}$$

Where, ζ is impact on strip crown from rolling force per unit width and unit bending force. K_{PB} is rolling force per unit width of the impact on the strip crown ratio. K_{FW} is roll bending force of the impact on the strip crown ratio.

When the roll diameter is constants, increasing the rolling force can lead to increase deflection roll and strip crown. Influence on the rolling force of the strip crown is:

$$K_{\mathrm{PB}} = \frac{\Delta C}{\Delta p} = \frac{C - C_0}{p - p_0} \tag{3}$$

Where, Δp is the rolling force per unit width change amount.

In order to avoid appearing adjusting the oscillation, rolling force fluctuation compensation dead zone is set up. When rolling force fluctuation is in compensation dead zone, feed-forward control is closed. When rolling force fluctuation exceeds compensation dead zone, feed-forward control is open.

Feed-forward adjustment amount model

The change of rolling force can lead to change in the distribution of the pressure of the roll gap. Elastic deformation of the roll is changed[5]. The extensional deformation is inconsistent along the width direction. The cont trol of work roll bending and intermediate roll bending on the shape is to change the load distribution within the seam roller pressure.

$$J = \sum_{i=1}^{\mathrm{N}} \left[\Delta P_i - \alpha_{\mathrm{W}} f_{\mathrm{W}i} - \alpha_{\mathrm{I}} f_{\mathrm{I}i} \right]^2 \tag{4}$$

Where, J is objective function. α_{W} is feed-forward correction work roll bending force. α_{I} is feed-forward correction intermediate roll bending force. $f_{\mathrm{W}i}$ is work roll bending force on the load factor in the regulation of the seam roller pressure distribution. $f_{\mathrm{I}i}$ is intermediate roll bending force on the load factor in the regulation of the seam roller pressure distribution. ΔP_i is measured rolling force variation.

In neural networks[6], there are N neurons in network input layer, Q neurons in competitive layer and M neurons in network output layer. The connection weight vector from network input layer to competitive layer is W_J. The connection weight vector from competitive layer to network output layer is V_l

(1) Initialize W_J and V_l. Choose value from 0 to 1. Normalize A_k as follows:

$$a_i^k - \frac{a_i^k}{\left\| A_k \right\|} \tag{5}$$

$$\left\| A_k \right\| = \sqrt{\sum_{i=1}^{N} a_i^k} \tag{6}$$

(2) Give k-th input pattern to the input layer of the network.

(3) Normalize W_J as follows:

$$w_p = \frac{w_i}{\|W\|} \tag{7}$$

$$\|w_p\| - \sqrt{\sum_{i=1}^{N} w_i^2} \tag{8}$$

(4) Sum each neurons in competitive layer as follows:

$$S_j - \sum_{i=\tau}^{N} a_i^k w_j \tag{9}$$

(5) Solve W_R as follows:

$$W_R = \max_{i=1}^{Q} \sum_{i=1}^{N} a_t^2 w = \max_{i=1}^{Q} s_i \tag{10}$$

(6) Adjust as follows:

$$w_R(t+1) = w_{R'}(t) + \alpha[a_t^2 - w_R(t)] \tag{11}$$

(7) Solve weighted input in network input layer as follows:

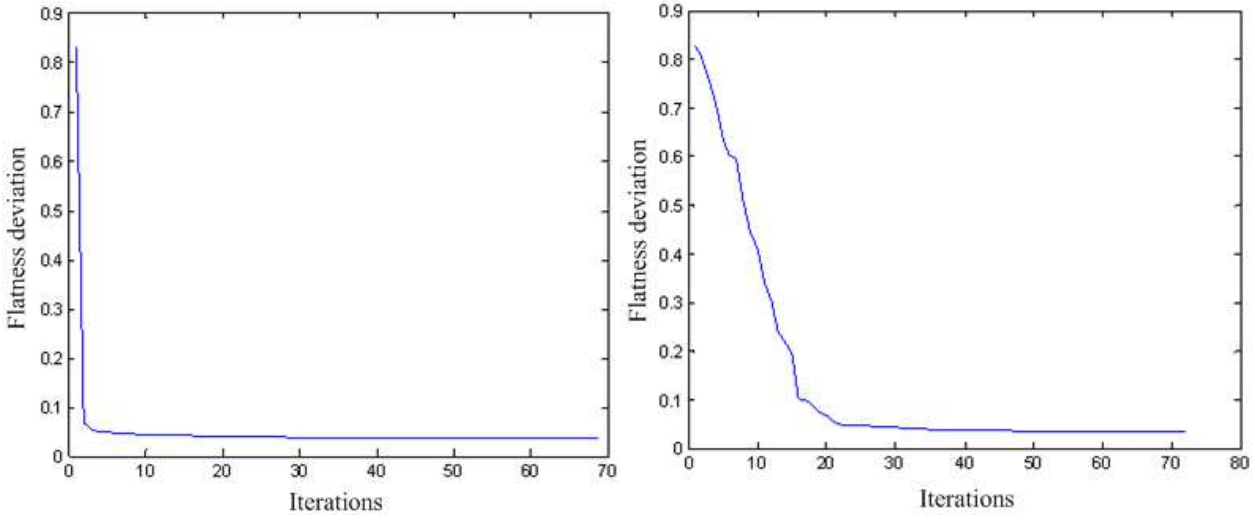
$$c_t' = \sum_{j=1}^{Q} b_j v_{ij} \tag{12}$$

(8) Return (2) until all input mode is given to the network.

(9) Set $t = t+1$. Assign value again.

Application results

The proposed flatness feed-forward control mathematical model has been successfully applied to a 1450mm five-stand cold rolling process control system. In order to verify its application results, the application results with flatness feed-forward control mathematical model is compared to the application results without flatness feed-forward control mathematical model. When the flatness feed-forward control mathematical model is not adopted, the deviation of strip flatness control is large. When the flatness feed-forward control mathematical model is adopted, the deviation of strip flatness control is decreased. Therefore, flatness feed-forward control mathematical model can increase flatness control accuracy.



a) with flatness feed-forward control model b) without flatness feed-forward control model

Fig.1 Variation of deviation of flatness

In fig.1, when the flatness feed-forward control mathematical model is adopted, we can see that the flatness is good in strip. When the flatness feed-forward control mathematical model is adopted, we can see that it appears flatness defection.

Conclusions

(1) The impact of roll temperature to flatness is analyzed and the roll temperature field model is established.

(2) The flatness feed-forward control mathematical model is established. The neural networks is adopted by the model to solve the feed-forward adjustment amount and the feed-forward adjustment amount of model can decrease deviation of strip flatness control, and the flatness quality has been increased greatly.

The Design of Greenhouse Environment Monitoring System Based on ZigBee

Chen Guoshao，Wang Zhongsheng ，Shang Xiao

Department of Computer Science & Engineering, Xi'an Technological University, Xi'an 710021, P.R.China,

Keywords: ZigBee; Serial communication; Wireless sensor network; Real-time monitoring

Abstract. The internet is widely used in daily life, of course, also be applied in agriculture. This paper is focus on the technology of ZigBee and serial communication. The ZigBee communication module transfers the data from greenhouse to the monitoring system. Growers can get the data timely, and according to the received data to control greenhouse environment. The monitor computer program is based on VB.NET. ZigBee module gets the data from sensor, through serial ports the information is transferred to the monitor computer. The monitoring software stores the data and displays it on the user interface. If the data beyond the threshold value, the system will give an alarm sounds.

Introduction

Greenhouse environment monitoring system detects greenhouse temperature, humidity and other environmental parameters, reducing workload of plant personnel. Records the data on time, convenient growers to control greenhouse environment, facilitate to the growth of crops. At present, the signal propagation mode in most of the greenhouse control systems are wire transmission, a large number of wiring is inevitable. It has many disadvantages, such as high cost, routing is complex, maintaining is difficult. However, the wireless transmission method can effectively solve the above problems.

The system designed in this paper, the data acquisition node is consists of single-chip computer, temperature sensor and humidity sensor, applies radio frequency technology for data transmission. The wireless node is to collect information and monitor computer displays it to the system interface.

ZigBee Technology Introduction

ZigBee is a low-power, cheap and short-range wireless network communication technology, it is used in almost all industries of low rate and short-range wireless communication, such as home furnishing, traffic, and building etc. Significant features of it are the low rate, low power, low cost, self configuration and flexible network topology structure. Due to in non working mode, the ZigBee node is in a dormant state. Because the ZigBee protocol stack is much simpler than others, reduces requirements of the controller, so we can use single-chip computer and a small amount of memory, to reduce the cost greatly. In the communication distance, it through the network coordinator setting network automatically, using the CSMA-CA methods for channel access; and the node device is free to join and leave, is a self-organizing network configuration.

System Structure Design

The system is composed of terminal node, coordinator (also known as the ZigBee gateway) and database management system. As shown in Fig 1, the terminal node is consist of temperature sensor and humidity sensor, collects data in real-time, the data through the C51 single-chip computer uploaded to the ZigBee wireless network. Each ZigBee module also has relay function, so as to avoid too far distance to transfer. The module is responsible for wireless transmission. Database management system applies VB.NET develop human machine interface. The terminal node is to collect and send data, database management system is to analysis and storage data. The coordinator

is responsible for collecting information through RS232 transmit to the host computer, and the system is responsible for realizing real-time display data, and to realize data storage, query, delete and other functions.

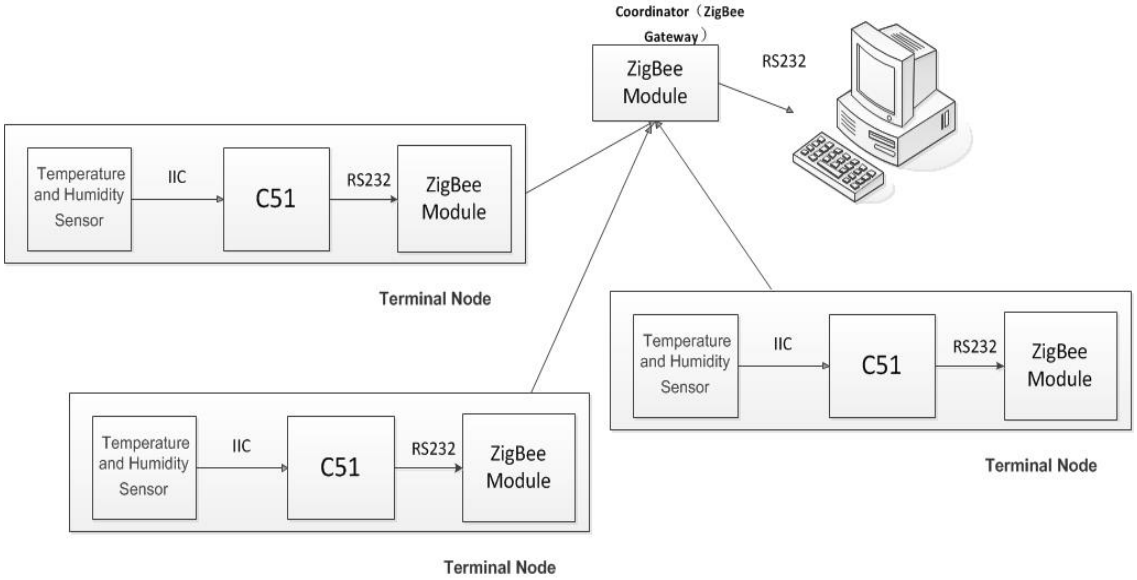

Fig.1 Structure diagram of system

System Hardware Designing

Environmental monitoring system hardware device is composed of terminal node and coordinator, as shown in fig 2. coordinator, it mainly includes microcontroller, RF sending-receiving unit, wireless node and power module and interface unit. From the system hardware, we should mainly consider the accuracy of the temperature and humidity, the detecting range and economic aspects. In this paper, the ZigBee module includes the integrated temperature and humidity sensor and CC2530.

The terminal node includes the temperature sensor and the humidity sensor, MCU and ZigBee module. The terminal nodes are placed in the greenhouse, the temperature sensor and the humidity sensor gets the information. Through the IIC bus MCU transfers the data to ZigBee network, then the coordinator transfer the information to database management system through the RS232 serial port. When distance the terminal node to coordinator is too long to transfer information directly, the data can be transfer to other terminal node, and then transfer to the coordinator.

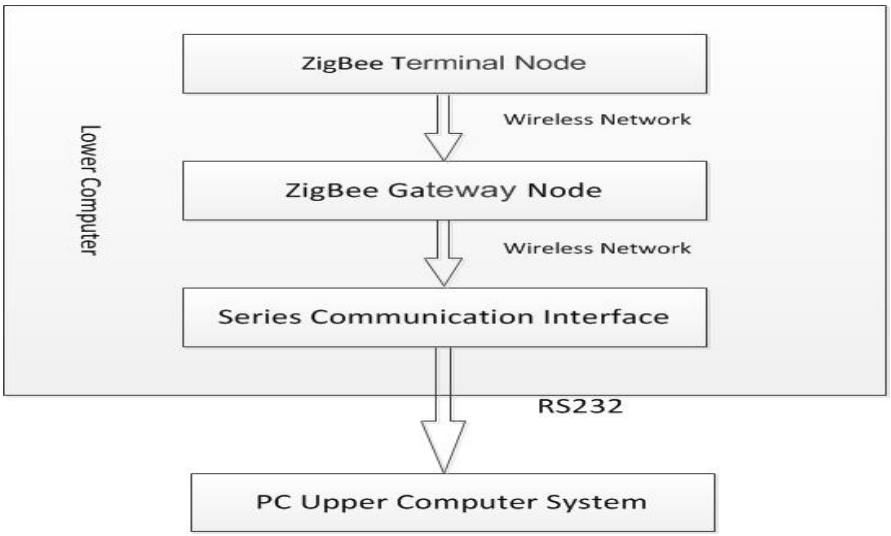

Fig.2 Structure diagram of lower computer system

System Software Design

The monitoring software is developed in Microsoft Visual Studio 2008 environment, the system transfers the data which is collected by terminal node to access database. Growers can through computer monitoring software query the history data, through monitoring interface monitor the data changes in real time, and can set the alarm threshold and the matching parameters etc.

Data Receiving Module

To transfers the data to database management system. The software is programmed In Microsoft Visual 2008, generally, we uses communication control of Microsoft Communication Control (MSComm).

Step follows:

(1) open the serial port connection (2) determine whether the terminal node parameters are correctly chosen (3) set the serial parameters according to the machine parameters (4) establish serial port communication events (5) receive data information.

Section code follows:

```
Private Sub SerialPort1_DataReceived(ByVal sender As System.Object, ByVal e As
System.IO.Ports.SerialDataReceivedEventArgs) Handles SerialPort1.DataReceived
        'introduce SerialPort class, receive data HOneData（the humidity of first node）three
group of six data
  Dim byteToRead As Int16 = SerialPort1.BytesToRead( )
        If byte To Read = 21 Then
            Dim ch(byte To Read) As Byte
            Dim bytesRead As Int16 = 0
            bytesRead = SerialPort1.Read(ch, 0, byteToRead)    'store the received data
  If ch(0) = 170 And ch(1) = 85 Then    ' judge whether the length of data is effective
              HOneData = CLng("&H" & Hex(ch(2) & ch(3))) / 10
              ……' transform hexadecimal into decimal（front），decimal point moves
single bit to the left(divided by 10）.
```

Data Processing Module

When the computer receives the data, the data be decomposed into three parts, the node number, values of temperature and humidity data, then the data will be transform hexadecimal data into decimal data, at last save to the database. Flow chart of data processing module is as shown in fig 4.

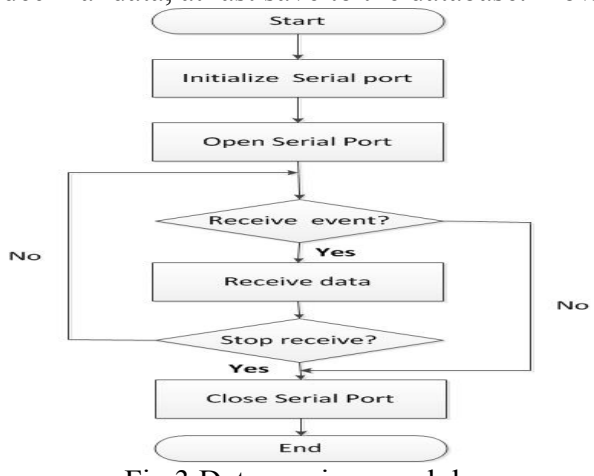

Fig.3 Data receiver module

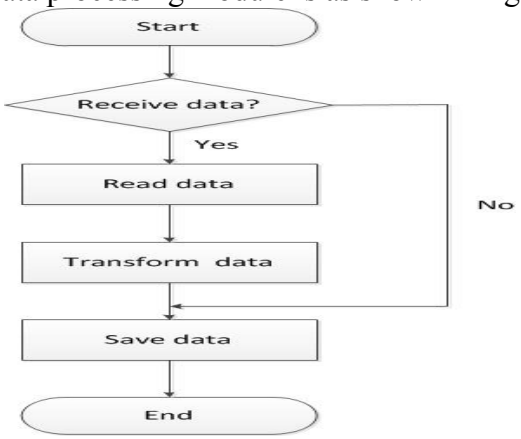

Fig.4 Data processing module

Section code follows：

```
Imports System.Data.OleDb 'apply access control
Public LHGconn As New OleDb.OleDbConnection("provider=microsoft.jet.oledb.4.0;" & "data source=" & My.Application.Info.DirectoryPath & "\NewData.mdb;") 'open database，relative path
    Public Sub LHconnopen( )
        Try
            If LHGconn.State < > ConnectionState.Closed Then LHGconn.Close( )
            LHGconn.Open( )
            Call RAlarm( )'database connection，alarm if error
```

Data Display Module

The data display module is the most important module in the system, GDI+ which is provided by.NET Framework converts the data to a picture, and displays it to growers. The system interface has two axes which are used to display the temperature and humidity data, through mathematical calculation to determine the coordinate value of the data on the axis. Connect adjacent coordinate points together to form a real time display curve. Use the Bitmap class to package GDI+ bitmap. Bitmap is used for processing image which is defined by the pixel data. The Graphics.FromImage can create a new Graphics from specified Image, at last using the PictureBox control to display the graphics and images.

Conclusion

The system detects temperature and humidity data based on ZigBee, it has many advantages, such as reliable, simple, flexible, low cost etc. The system can collect real-time data and transfer it to the user, the user can timely grasp the greenhouse environment, so as to adjust and control the environment, and there are values of application.

The design of portable granary thermometer

Gang Qin[a], Dequan Cui[b]

Xi'an Technological University, Electronic-Information Engineering College Xi'an, China

[a]494524028@qq.com; [b]Cdq061002@163.com

Keywords: msp430f149; temperature collection; portable; low power consumption

Abstract. This article designed a portable granary thermometer to solve the shortcomings of present similar products ,such as complex structures , high performance price ratio and lack of flexibility , this thermometer used ultra-low power microcontroller MSP430F149 and programmable temperature sensor DS18B20 as the main components, it can collect, display and store the temperature on a real-time basis . Based on actual use, this apparatus possess the advantage of complete function, low power consumption, easy to operate, low price, portable and wide occasions of application etc.

Introduction

Granary thermometer an instrument of detecting grain temperature in the granary. With the development in science and technology, our domestic granary temperature measurement system develops greatly. In ordinary, the system adopts classification structure made of measuring host machine and slave machine. Main machines are placed in the side of the computer to collect and store the data, and then transmit the temperature data to the computer through serial ports; Measuring extension machines are installed in the warehouses of the granary, the extension number is corresponded with warehouse number. Therefore, the temperature signal processor is indispensable in the granary which also should be supplied power by utility power. The temperature measuring cable generally made of several connecting wires which connected to signal processor, the complicated structure with many signal cables and power cables, so that it is hard to install, maintain and with high cost. Some small granaries are not suitable to install the equipment said above for the sake of technology and funds. According to above problems, one kind of portable granary thermometer was designed which is convenient to measure the temperature, so that granary keepers could be more intuitive to know the change of the temperature in the granary. It has following features high measurement accuracy, small volume, low price, portability etc. It is mainly applied in small and medium granaries to realize the monitor of granaries through measuring and storing temperature.

System Hardware Composition

Portable thermometers mainly consist of microcontroller modules, data acquisition modules, data storage modules, display modules, clock modules and power modules. Hardware structure is shown in figure 1.

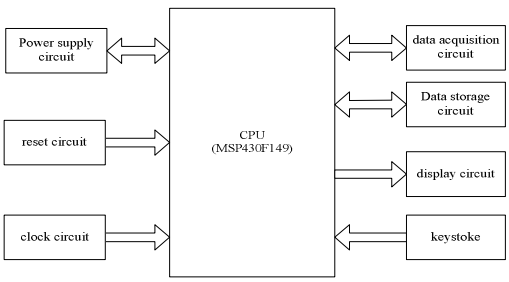

Fig.1 Hardware block diagram

A. Microcontroller Modules

Low power consumption is most important in the design of portable equipments. On promise of the design, Microcontroller should not only work in low voltage but also has lowest power consumption for power. Supplying with battery reason. In addition the anti-interference ability should be also considered in system design, especially for portable system design, so choosing the suitable system core devices is the key to finish the design successfully, and microcontroller is the most important as the core of acquisition system. This text is to study a portable granary temperature measuring system which is convenient to detect in the field, display and store the data, and then send the data to upper computer terminal for analyzing when needed. Considering hardware resources, development tools, and power of microcontroller, ultra-low power consumption microcontroller MSP430F149 of TI is applied in this design as the core controller of the portable thermometer.

B. Data Acquisition Module

Using sensors to collect temperature data of the grain. Early temperature sensors usually use copper resistance, thermal resistance or thermocouple as sensor elements, which reflect the changes of grain temperature through examining the variation of resistance value, but it is inefficient, inaccurate, and insensitive to carry out the work bit by bit by manual operation. Considering measuring accuracy, range, economy efficiency and other factors, DALLAS DSl8B20 is chosen as the thermometric element which is the unibus digital temperature sensor made by DALLAS with the features of simple structure, operation flexibility, and no need of external circuit. DSl8B20 interface is shown in figure 2.

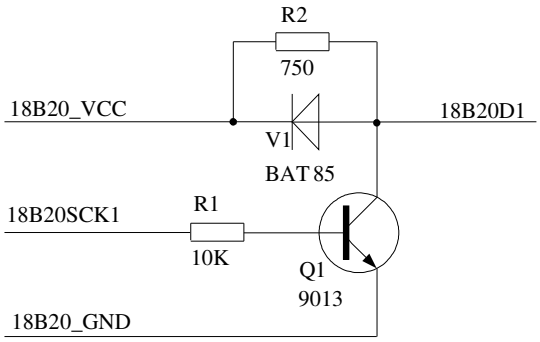

Fig.2 DS18B20 interface circuit

C. Data Storage Module

The main advantages of this kind of thermometer are portability and convenience so that the data measured is easy to store and transfer. Therefore we should consider the portability and dismountable performance of the data storage medium. Because the system does not belong to fixed real-time measurement, when there is a need to measure the temperature of the granary, the system will collect the data, after finishing the measurement, workmen could take the data away for further research and analysis. Since SD memory card could meet the above requirements, we choose SD memory card as data storage.

SD cards mainly store the measured temperature and humidity data. When the SD card works, it needs to be drived and managed by a control chip CH376, which is used to connect SD card with the microcontroller, and manages the data transmission between them. SD card interface circuit is shown in the figure 3 :

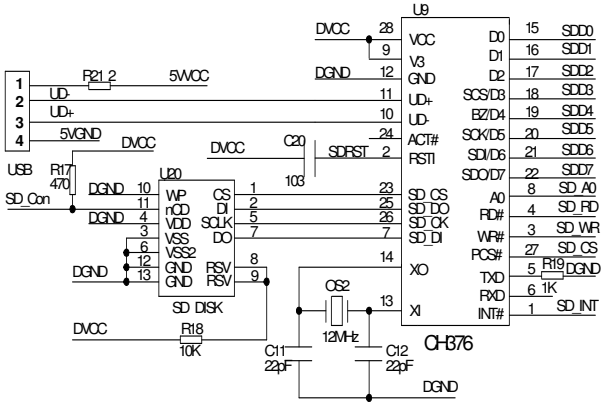

Fig.3 SD card interface circuit

It adopts directcurrent supply 3.3Vas the power supply source, so V3 terminal and VCC should be connected to DVCC together. UD- and UD+ are used to be the data input and output for the spare U Disk socket. Two 22pF in 12MHz crystal oscillator are used for oscillation starting and frequency stabilization. The pin SD_CS, SD_CK, SD_DO, SD_DI connect with SD card slots as chip selection, clock, data input and output terminal

D. Display Module

Common used LCD module mainly has physic and dot-matrix types. The design uses dot-matrix LCD module YM12864C. It mainly drives by adopting the dynamic driving principle -- controller and segment driver make a 128 (column) x 64 (lines) full dot-matrix LCD display. The display monitor adopts COB soft packaging mode, to connect LCD through conductive rubber and pressure box connection which makes its long life and reliable connection.

Due to the low data and control signal voltage outputted from microcontroller parallel ports, display module needs to increase drive chip to enlarge signals, enhance load capacity, which could make YM12864C work normally. Drive chip adopts TTL 74LS245 chip. The microcontroller could enhance the load capacity through this chip to control the LCD module data. Interface circuit is shown in figure 4.

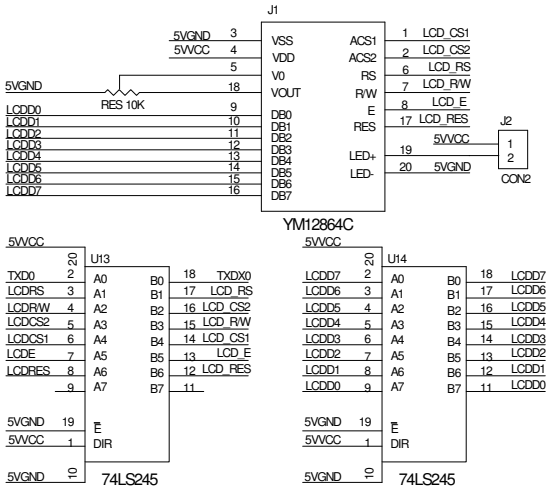

Fig.4. LCD interface circuit

E. Clock Module

The clock modules in granary temperature measuring system are to provide workmen with the time and data. The microcontroller configures the chosen chip to finish the display and data remark after measuring data. The clock chip is PCF8653 which is a low power consumption CMOS made by PHILIPS. It provides a programmable clock output, interrupt output and power down detector.

F. Power Module

Power supply is the system dynamics in the granary temperature measuring system. The reliable power is the guarantee of the normal work of the system. The thermometer adapts 3 V button batteries which doesn't need utility electric. This also shows portable features. Since various elements may need different working voltage, power supply should be regulated. Using stabilivolt L6920 and SP6201 and relative external circuit could get 5V and 3.3V voltage.

3.3V voltage is mainly used for 430 microcontroller, I^2C storage, SD card, four-key keyboard, JTAG programming interface power. These parts need much reliable voltage, or the core of the system could not work normally.

5V voltage is mainly used for temperature sensors, LCD display module, clock chip, external benchmark source power supply. These parts also need reliable voltage or the system time will disorder, sensors and LCD screen doesn't work normally.

System Function and technical indexes

System function is shown in the figure 5.

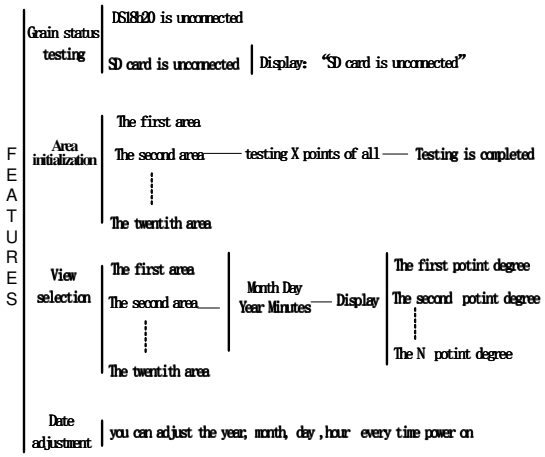

Fig.5. System function diagram

- Grain status testing function : First display area, scroll by up/down keys, choose area by clicking "ok" to collect real-time data of grain temperature, warehouse temperature, and warehouse humidity. It shows "spare" at the time of no value, and shows "finish detection"if nomal（automatic storage）.
- initialization function：First display area, scroll by up/down keys, choose area by clicking "ok ",then initialize to recognise the code with DS18B20, then click "ok", Don't need to initialize after a period of fixation.
- View function selection：First display area, scroll by up/down keys, choose area by clicking "ok" to show the time. croll by up/down keys, choose date by clicking "ok". Display according to DS18B20 sequence,four points（N, N+1, N+2, N+3）are a screen. Scroll by up/down keys to check by every screen and area.
- Date adjustment function：Show the latest year firt, scroll by up/down keys to choose year by clicking "ok". It is the same way to choose month, day, hour, sectond, and hour is responded with 24 hours.

Technical indexes Thermometer could achieve 0.1℃ resolution, less than ±0.1℃ measurement error. Working temperature is -40℃~ +85℃, 2.4V button battery power supply it could work more than 2 years with not changing the battery.

System Software Design

The main function of portable granary thermometer is to measure the temperature of grain in warehouse. The system uses microcontroller to program storage extension procedure and read or write extension chip, to finish the temperature measurement, LCD display and data storage.

Integral software flow chart of the system as shown in figure 6

Conclusion

The portable granary thermometer introduced in this text has many advantages such as small volume, simple operation, high accuracy and convenient detection. It could detect any granaries flexibly, the detected data is easy to store and transfer which could be taken away by workmen for further research and analysis. This system is much suitable for the small and medium granary. It has a great practical value and application prospect.

Research and design of light moisture tester

Yaping TANG

Hunan Railway Professional Technology College, Zhuzhou, 412001
398741983@qq.com

Keywords: Light moisture meter; The coal quality analysis; Through nitrogen drying; The heating rate

Abstract: This paper introduces the research and design of a light moisture tester. In the coal quality analysis field, moisture test most of the use of infrared heating pipe heating or drying box to measure, low heating rates, nitrogen through a single mode, before heating furnace uniform nitrogen filled with test conditions and have the test conditions, the same way caused by nitrogen, nitrogen waste. Based on this study, the heating pipe comprises an infrared tube into a light tube, the heating rate is improved; the general nitrogen control size flow switching mode using 2.5min before the experiment, large flow quick heating furnace filled with nitrogen, achieved through experimental conditions drying nitrogen, open a small flow, keep the atmosphere. The improved design of a light moisture meter analysis of water air drying method precision test, analysis of water air drying method accuracy experiments, 6 water - air drying method of precision experiment, 6 water - air drying method accuracy experiments, analysis of water through nitrogen drying method precision experiment, analysis of water. Nitrogen drying method accuracy experiments, ¢ 6 full water through nitrogen drying method precision experiment, ¢ 6 full water through nitrogen drying method accuracy experiments, results in line with national standard test, repeatability.

Introduction

Water is an important indicator of coal, which have an important role in the basic research of coal utilization and processing. Coal processing and utilization of its water, trade and storage and transportation has a significant impact. Generally high water is not a good thing. Combustion in the boiler, the water will affect the combustion stability and high thermal conductivity; in the coking industry, high moisture will reduce the coke yield, and because a lot of evaporation of moisture and heat away to extend the coking cycle; in coal trading, coal moisture is an important measure of the quality and count. In the coal analysis, coal moisture coal analysis is the basis of the results of different data base conversion. In the field of coal quality analysis, water testing most of the infrared heating tube to measure the blast oven or using a heating rate of low nitrogen-way single, uniform heating furnace filled with nitrogen test conditions before and after the test conditions have, through nitrogen same way, wasteful of nitrogen. In this paper, based on this study, infrared heating tube light tube to tube, increasing the heating rate; nitrogen is controlled by the size of the air flow through the switching mode, before the experiment 2.5min open large furnace filled with nitrogen flow so fast, to pass nitrogen drying experimental conditions, and then open a small flow, keeping the experimental atmosphere.

The principle of the test system

A certain amount of coal samples, placed in a furnace, coal water molecules under the action of heat, moisture evaporates quickly calculate total moisture or water based on mass loss analysis based coal samples after drying.

Instruments hardware system design

Overall block diagram of the hardware design. Entire hardware system includes the following main modules: SCM control module, light heating pipe heating module, thermocouple module, AD sampling module, over-temperature, burnout hardware protection module, nitrogen module, power module. The hardware block diagram shown in Fig. 1.

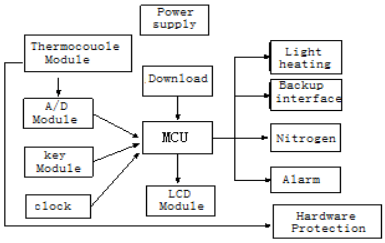

Fig. 1 Instrument calibration flow chart

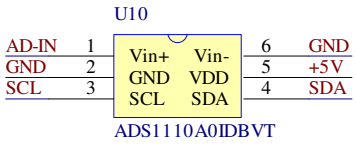

Fig. 3 AD sampling module

The main hardware circuit module design. Thermocouple Module: K-type thermocouple (consider the effect of a good loss prevention sheathed thermocouple), pre-amplifier AD620 op amp, amplifier taken magnification 50.4 times. Cold junction temperature measured by the temperature measurement chip LM75A. The design principle shown in Fig. 2.

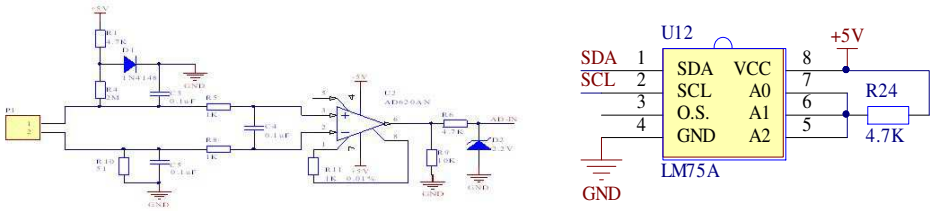

Fig. 2 Thermocouple module principle diagram

A-D sampling module: AD sampling chip ADS1110A0IDBVT, this lower chip prices, small size, fewer external components, high-precision (16-bit). The principle shown in Fig.3。

Light control circuit heating pipe: Using two heat pipes, each heat pipe 1.25KW. Modulated wave to the microcontroller output thyristor power regulator for heating pipes. 2 after heating tubes in parallel with the thyristor connected in series, while the over-temperature, Burnout series hardware protection relays, and then through the switch and fuse access AC220V grid (where a heating tube is connected in series with a relay, can disconnect the power supply itself alone). Using the heating tube 2 may be beneficial to fine temperature control, if the heat pipe 1 2.5KW same effect can be achieved, will consider only A heating pipe.

Instrument System Software

Instrument software system designed by CAN communication, laboratory module, Temperature module, AD converter, the abnormality detection of several parts. CAN communication is completed with the upper and lower bit machine data exchange, independent of the experimental module to complete the data acquisition components and related need to perform the entire experiment, monitoring, temperature module is mainly calculated by table look-up and calibration temperature, while the PID algorithm achieve temperature control. AD converter module is handled automatically by the SCM process, the software only on the relevant registers corresponding configuration; anomaly detection module is the main program loop timed to judge the state of the system-related, such as abnormal then upload exception message while locking the corresponding action parts until the fault is removed。

Test

Through hardware and software design of the light moisture tester meter air-drying method for analysis of water precision test, analysis of water and air dried Law accuracy of the experiment, ¢ 6 all-water air-drying method precision experiments, ¢ 6 all-water air-drying method accuracy experimental analysis of water through nitrogen drying method precision experiments, analysis of water through nitrogen drying accuracy experiment, ¢ 6 full water through nitrogen drying method precision experiments, ¢ 6 full water through nitrogen drying method to verify the accuracy of the experiment, the test data as follows.

Analysis of water drying method precision experiments									
Experimental conditions: heating time: First 480s, Second 360, Third 360s, 360s thermostat incremental point: 107 ℃

Summarizes the data analysis and experiments

This design light moisture tester entire disk with precision seed samples meet the national, standard requirements, no systematic bias. Selected for high, medium and low moisture coal sample experiment, the light moisture tester moisture analysis, experimental results ¢ 6 total moisture with infrared heating tube heating water meter, compared with higher efficiency characteristics, the test results we meet the national standard.

Keywords: USV, Software System, PCI8602, VB

Abstract. The design of software system for unmanned surface vehicle using PCI8602 is introduced. The software system includes the drive program of PCI8602, wireless transmission program and master controller program. Visual Basic is used to write programs, which doesn't write complicated communication protocols between each layers and integrating subsystem is easy. At last, the experiment results demonstrate that the control system for USV has a way to real-time acquisition data, sending data and accomplishing remote control.

Introduction

Unmanned Surface Vehicle (USV) is an intelligent and unmanned surface platform, which can navigate autonomously in the marine environment and complete various tasks such as environmental perception, target detection. At present, many countries have carried out relevant research in the unmanned vehicle, and U.S. and Israel stand at the forefront of study and application in USV fields. In civilian, it mainly includes USV[1] of Massachusetts Institute of Technology in USA, SESAMO USV[2] of National Antarctic program in Italy, DELFIM USV[3]of the Portuguese system and robotics institute, edredon USV[4] in Poland, Measuring Dolphin[5] in Germany and so on. In military, it is represented by Spartan USV[6] in USV and Protector USV in Israel. In China, USV technology is still in the conceptual starting phase.

USV has become new hot spot area of robotics research, to which extensive attention are paid from scholars at home and abroad. State oceanic administration subsidizes Shanghai ocean university, and Shanghai ocean university is studying the control system of USV, and draws some conclusions after many experiments. In the paper some phased objectives are presented as follows.

Introduction to Control System

The control system of USV in the project is divided into USV carrier, shore-based monitoring system and wireless transmission system. The way it works is that shore-based monitoring system is keeping the data, correcting the position of USV carrier and controlling the speed of USV carrier according to the way of comparing the data with expect data, and the data mainly includes longitude and latitude which comes from differential global positioning system which is installed on USC carrier while USV carrier is sending the data to shore-based monitoring system through wireless transmission system.

Fig. 1 The hardware system of the prototype

The hardware system of the prototype is shown as Fig. 1. USV carrier mainly includes: IPC, PCI8602 data acquisition card, differential global positioning system, propellers, battery and other

sensors. The master controller is an IPC and PCI8602 data acquisition card. IPC connects with debugging interface by TCP protocol and connects with differential global positioning system by serial ports of RS232. PCI8602 data acquisition card controls DC motor installed in propellers and collects the data which comes from other sensors. Shore-based monitoring system mainly includes PC computers, and it communicates with USV carrier by wireless transmission system.

So the work pattern of the control system is IPC of the bottom layer in USV carrier and PC computer of the top Layer in shore-based monitoring system. The manipulation is remote control and autonomous operation. The drive mode is two propellers, and two propellers produce speed difference to achieve swerve.

Software System of USV

The Drive Program of PCI8602. The advantage of PCI8602 data acquisition card is that the users do not care of hardware of control in detail but sampling frequency and so on. Then it collects and outputs the signal according to some simple functions in the software package of relevant drive program.

Table1 The explan of functions of drive

Name of function	Explain of function
CreateDevice	Create PCI device object (logical unit numbers)
CreateDeviceEx	Create PCI device object (physical device numbers)
ReleaseDevice	Close the device, and release the PCI bus device object
InitDeviceProAD	Initialize the device of AD，and be ready to transmit
SetDevFrequencyAD	Dynamically change the sampling frequency of AD
StartDeviceProAD	Start the device of AD，and begin to switch
ReleaseDeviceProAD	Release the device of AD
InitDevProDA	Set the output range of the assigned channel of DA
WriteDevProDA	Write the data of DA
GetDeviceDI	Switch the input function
SetDeviceDO	Switch the output function
RetDeviceDo	Backward read the state of data output

In the project, VB is written to control the drive program of PCI8602. Because the drive program is object-oriented programming, a hDevice of object handles is created by a function of CreateDevice before all objects are used. If getting the hDevice, absolute control of the object will be got. Then the hDevice which is taken as the parameter transmits to some relevant drive program. At last, it is released by the function of ReleaseDevice. Table1 lists the main function of drive in the software package of relevant drive program.

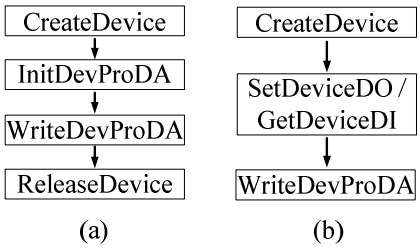

Fig. 2 The calling sequence of function

The master controller mainly uses the function of input and output of DA analog quantity and the function of input and output of DIO digital quantity in PCI8602 data acquisition card, and their calling sequence of function are shown as fig. 2(a) and fig. 2(b). According to figure 2 and the service regulations of PCI8602 drive program, the input and output of DA analog quantity and the input and output of DIO digital quantity are achieved.

Wireless Transmission Program. A pair of wireless transmit units connect with IPC on USV carrier and PC computer on the shore-based monitoring system by serial ports of RS232, and at the same time MSComm in VB reads and sends the data at RS232, so the data enters into serial ports of RS232 of IPC and PC computer, after determining series rate, transmitted power, radio frequency rate and so on, and then MSComm reads and sends the data of serial ports of RS232. At last achieve the wireless transmission.

As mentioned, the wireless technology has been mature and they are immediately applied to the project, so the key to the wireless transmission program lies reading from and sending to serial ports of RS232 in real time. Calling MSComm controls is more convenient than calling API function in practice, and it use less code to achieve the same function.

According to the under steps which call MSComm controls can read and send the data of serial ports of RS232.

(1) Add communication units that is MAComm project.

(2) Set numbers of communication port that is CommPort property.

(3) Set communications protocol that is HandShaking property.

(4) Set parameters such as speed of transmission and so on that is Setting property.

(5) Set other parameters, and add other properties in necessity.

(6) Open ports of communication, and set PortOpen to be true.

(7) Send or read character string, and use input and output property.

(8) Close ports of communication, and set PortOpen to be false.

Follow the steps above, which establishes the transmission system of serial data. Notice that step(2) to (5) is set in properties window of design environment and set in programs, and step(6) to (8) only set in VB.

Master Controller Program. After calling MSComm controls to read and send the data of serial ports of RS232, the VB function editors of character string are used, for instance, Instr function which cut out commands of data and then the master system responses according to commands. The relevant commands in the system are shown as table 2.

Table2 Commands of system and system responses

Command	Response
Start	Begin the command
Over	End the command
Right	USV turns right
Left	USV turns left
Forward	USV goes forward
Back	USV goes backward
Stop	USV stops
H_Sc_	Govern the speed of USV
H_Ch_	Govern the speed of USV
Value	The speed value of USV

Every command in the data starts with ‘ Start’, and ends with ‘Over’, so the system begins to cut out commands, when the system detect ‘Start’, and the commands end, when the system detect ‘ Over’. As above, on the basis of wireless transmission program, master controller program mainly consists of the VB function editors of character string which detect and response commands of data, and the system responses is mainly according to the drive program of PCI8602.

Water Experiments

The control system of USV in the project has made some experiments on the water, and the results of Z tests and rotary experiments have introduced as follows. The results of water experiments are shown as Fig. 3.

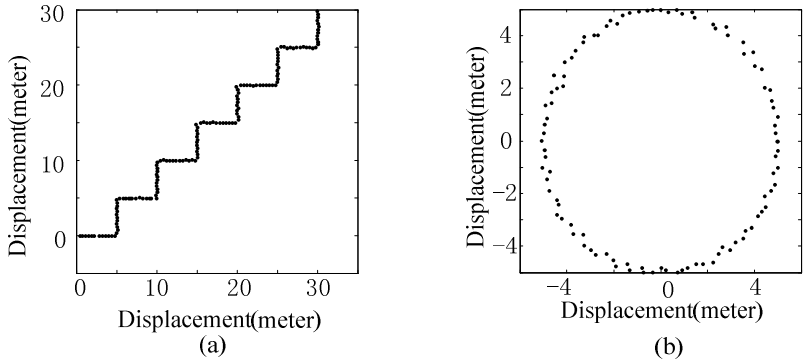

Fig. 3 Results of Water Experiments

USV carrier was remotely controlled to reach the center of lake, and the course was 0° at original state, and the rated speed of motors were 1370 (r/min). After the Z test began, the left motor turned positive direction of rotation at the rated speed and the right motor turned negative direction of rotation at the rated speed. Then, after USV carrier turned to the other side, the rated speed did not change, the left motor turned negative direction of rotation and the right motor turned right direction of rotation. Later, repeat the first step after USV carrier turned to the other side, and cycle all over again until the experiment ended. After the rotary experiment began, the left motor turned positive direction of rotation at the rated speed and the right motor stopped, until the rotary experiment ended. At last, the experiment results show that each systems were in good conditions, and the control system for USV has a way to real-time acquisition data, sending data and accomplishing remote control.

Conclusions

The key to the control system of USV in the project lies PCI8602 data acquisition card, and its advantage is described as follows. It does not need to write complex communication protocols among each layers, which reduces the difficulty of programme and it is easy to integrate each subsystems. At last the results of experiments demonstrate that the control of USV meets expectations, and the way of design is feasible.

Keywords: Multi-display, Mobile Terminal, Instrument

Abstract: Nowadays, the mobile display devices have become the most significant section of the mobile terminal. During nearly a decade development, lots of display technologies have been maturely applied in the mobile terminal instrument. This paper analysis the integrated application of several display technology utilized in mobile devices according to their characteristics, and predict the tendency of their development in the rapidly development stage of 3D display. Mobile terminal has become the mainstream of IT equipment, including intelligent mobile phone, pad computer and so on which is at a rapidly developing stage. On the other hand, currently technology on human machine interaction is concentrated in display devices, touch screen for instance.

Mobile Terminal Technology and Its Development

Multi-display technology has become the concentrated reflection of novel display technology, and the consisted technologies of this are:

Liquid Crystal Display (LCD) Technology

Since the LCD technology firstly emerged in the 1990s, with many technical evolution, as the result of different developing stage, many different products came out and each of them appeared various characteristics, shown in.

Table.1 Selected LCD Technology and Their Characteristics

STN	TFT	TFD	UFB
● Low energy consumption ● Mainly display light green and orange	● Short response delay ● Wider visual angle	● Less energy consumption than TFT ● Higher display quality	● Contrast radio is twice than STN

In terms of manufacturing methodology, two main processes are present below:

Low Temperature Poly Silicon (LTPS): Low temperature poly silicon (LTPS) enjoyed a significant statue in the development of LCD display technology. From the view of technical, LTPS could enhance the transmission capacity of panel so that some complex electric element could connect to the screen directly, which could realizing the function without being depended on the high cost individual parts and complex interfaces.

Continuous Grain Silicon (CGS): By contrast, Sharp's continuous granular crystalline silicon, by contrast, patent technology enables the company to develop than regular LTPS smaller screen size, higher resolution of the display screen, due to CGS could perform better than LTPS in Electron transfer properties.

Organic Light-Emitting Diode (OLED): OLED compared to the LCD manufacturing process is simpler, it only USES two thin film and glass or plastic substrate. Electricity enabled, layers of organic molecular materials will emit light, the display effect than LCD brighter and more exquisite, can also be very obviously save power consumption. Because of the OLED can our own light shine, so there is no used for LCD back light etc.

The laser projection

Using high power laser projection of red, green, blue (three primary colors) monochrome laser as the light source, there are many methods to realize scanning line and field, when the scanning speed

is larger than the critical flicker frequency imaging, can satisfy the requirement of human visual residue, the human eye can be observed clearly. Critical flicker frequency is observed periodic goal just can't feel the blinking frequency.

Due to the laser possesses the characteristics of high brightness, good directivity and the laser projection of long distance, large screen display advantage is unmatched by any other method:

(1) projection can be surface can also be a plane surface, can be a fog (smoke and steam fog), water, also can be metopic, curtain, or flat ground glass, so long as is light scattering material;

(2) By the three primary colors mixed into a rich color hue saturation;

(3) NO afterglow phosphor, background clean, high contrast;

(4) Owing to no need of big heavy screen, the whole system is small and light, easy to carry.

Integrated application of multi-display technology in mobile terminals

In the smartphone or tablet, mobile computing, to achieve different functions, the need to adopt different display technology integration application. In the future, a variety of display technologies to mobile terminals are the carrier play their role. Especially in the area of 3 d display related technology, mobile terminal has its unique advantages, such as can integrate all kinds of sensors, video collection equipment and the new type of display device miniaturization. Under the integrated application of many kinds of display technology, can create a lot of new applications.

The display and lighting related aspects

Mobile terminals such as smart phones in addition to the main display, also need to match other semaphores, message light, signal lights or rechargeable lights and flashing light. Part of the mobile computer keyboard backlighting is needed.

The attached show generally using LED light source, its advantage is that energy consumption is small, can play a prominent role at the same time.

3D Augmented Reality Network Game

3D game refers to give a person with a 3D game feeling. Conceptually, 3D game is using 3D model to make the characters in the game, such as the scene, allowing players to experience in the game three high three dimensions, from different angles for the game. This will greatly increase the degrees of freedom, fun and authenticity of the game. The current 3D game has become the market mainstream type of game.

Combined with the real scene shooting 3D online games can use the 4G era of large bandwidth, bring brand-new feeling, can largely reduce the distance of the people at the same time. Make the game is not only a man and machine communication, more become the carrier of communication between people.

3D Augmented Reality Electronic Commerce

At present, e-commerce site, product distribution and display are mostly based on hypertext links and two-dimensional image, the limitations of the technology more or less restricting the development of electronic commerce.3D with 3D technology as the core of e-commerce, shopping environment and shopping behavior simulation of reality, and through the merchants "face to face" communication interaction with customers, to create a consistent with the reality of the virtual network commercial shopping environment. It not only can show the appearance of the product, quality, comprehensive features, automatic demonstration function and operation method, under certain circumstances may even be able to open the shell to check the internal information. For one commodity, consumers can use their own virtual model fitting; In addition, you can actively match product components, customize their favorite style. 3D augmented reality reflects the e-commerce network economic characteristics of the consumer demand oriented.

Mobile Internet 3D video

Network video is a popular application of the Internet in recent years, the birth of many listed companies such as Youtube and youku potatoes. At home, the network video industry relative good momentum of development, is China's netizens after instant messaging, search, music, news of the fifth largest applications. With the development of the market, users of network video content and

quality also put forward higher requirements; with the rapid development of 3D film and television works, network video industry is gradually introduced into 3 d content.

3D Augmented Reality Mobile Navigation Service

The popularization and application of intelligent terminal, APP development market, make the development of mobile Internet business of 3 d and augmented reality also ushered in the opportunity. Enterprise can with the aid of augmented reality, and make full use of the advantages of apps, on the basis of 3 d display, overlay virtual information, achieve the enhancement purpose to the field of vision, present a more comprehensive navigation information to users, to make up for the current most of the two-dimensional information is not comprehensive.

Mobile terminal display technology development direction

Can a new type of three dimensional display applications on mobile devices at present main direction are based on the plane of 3 d display technology. Based on the plane of 3 d display technology has the following several main developing direction.

Double viewpoint double LCD system

Sharp, one of the design of a single light source by the beam splitter can be divided into two beams, respectively, after both sides mirror reflection as two sides of the LCD background light, to illuminate two LCD, again through the beam splitter can be divided into two beams of light. If the two sides about a pair of 3 d image of LCD, is in the figure shows the eye will see stereo images. This method has the advantages of high brightness, high resolution, but can only be seen in a specific location stereo effect

Double viewpoint single LCD system

Barrier Gate System: In the barrier gate stereo display system, barrier gate can be placed in front or rear of the observer LCD, studies have shown that front grating can be made to observe the visual areas achieve good observation of light intensity uniformity and observe the effective width, and then set about grating can make the image of interference is smaller. Usually adopt the front barrier gate to achieve stereo display.

Micro Lens Array Design: Micro lens array is similar to barrier gate, also have a stagger around view sequences were projected to the left and right eyes visual function. Besides have the characteristics of principle of barrier gate, Polaroid stereo display can also adjust the Polaroid polarization direction of the transition of 2 d and 3 d display mode, which is one of the advantage of its application prospect is good.

Multi-view System: In order to realize many different angles to watch different image at the same time closer to reality. The PHILIPS Company of stereo display technology research is based on the traditional method of micro cylindrical lens. The company auto stereoscopic LCD monitor is in front of the LCD screen, add a layer of micro cylindrical lens make LCD screen like plane on the focal plane of the lens. Under each column lens are divided into several sub pixel, pixels of the image that can be in a different direction projection lens each pixel, eyes watch display, from different angles to see different sub pixel.

Four perspective stereo display device

Japanese Sanyo in 2004 put forward a four Angle of stereo display device, this method is similar to PHILIPS method on the basis of the principle of micro lens. Through four cameras placed side by side, 4 parallax image of target is obtained through format conversion, the four picture pixel level and horizontal staggered to flat display device, which can be seen in the three visual areas target different perspective of the three-dimensional images. It draws on multi-view stereo display method of the PHILIPS company could realize in the barrier gate, this method also has the same border stripe down and image deformation reduced proportion.

NEC LCD Technology HDDP Three-Dimensional Display

Announced in October 2008, NEC LCD technology, successfully developed the naked eye can see the three-dimensional image 31 cm (1211) in amorphous silicon TFT LCD screen, 800 @ 600 pixels (SVGA), mainly used for movies and games and other entertainment, Digital Signage

(Digital Signage), and industrial use CAD and resolution of images for medical use of industrial equipment and so on.

The integration of a variety of display technology in the Pudong new area

A variety of display technology in the Pudong new area has been part of relevant enterprises, how to promote the enterprise application and technology integration development, the relation between the whole display industry and mobile Internet industry is very important. With the advantages in the Pudong new area, existing relevant enterprises and economic development, the integration of a variety of display technology development is in the following aspects worthy of attention.

3D display technology is to be active and to the naked eye 3D. From a technical point of view, glasses-free 3D technology is the trend of the development of the 3D; And from the perspective of the consumer need to wear special glasses in order to appreciate the elegant demeanor of 3 d technology, there is the inconvenience of use. And 3D content is also the important driving force of the 3 d technology, the advance of the Pudong new area, including science and technology museum, the exhibition group such as exhibition could combine related 3 d content, the popular science activities, should be able to promote the promotion of new display.

As the 4G mobile communication standards and the development of the three-dimensional Internet business, mobile terminal hardware platform put forward higher request to the user. Pudong new area of the application of various IT leading enterprise for a variety of display technology even more consideration to the new hardware and software combination of the audience.

Facing the challenges of the battery, introduction and use of all kinds of new business need durable high capacity battery, 3G, the big screen, data interaction and the future of open 3D technology puts forward higher demands on batteries. Now is still the mainstream of the market, lithium-ion batteries in the battery itself under the condition of performance is not strong, mobile phones more and more thin, more and more light, the battery will only become more and more small room to play. With the development of battery technology, in addition to lithium batteries, lithium polymer battery, fuel cells, biological cells, solar cells, such as technology also in development, but do not have it in mobile terminal to realize the commercial scale. How to provide more sufficient power for mobile phones, so as to prolong the life time of the mobile phone, will be a worth studying for a long time.

Design of remote monitoring system of temperature and humidity based on Internet of things technology

Lei Wang*

School of Jianqiao University, Shanghai 201319, China

*gench_wl009@126.com

Keywords: The Internet of things, Sensor, The AVR kernel, RS485 bus.

Abstract. Design a things related technology based on remote monitoring system of temperature and humidity, sampling using SHT10 digital temperature and humidity sensors, temperature and humidity variables, and data transmission through the RS485 serial bus interface, using AVR kernel 8 bit chip for processing, resulting in a host computer display temperature and humidity changes, the indoor multi node the environment through the test, system has stable function, good display data change, relatively low cost advantages.

Introduction

Temperature and humidity monitoring production industry in the people's home life,, has great application prospect in agricultural planting and other aspects, the traditional application in the monitoring of temperature and humidity is mainly depend on the mercury thermometer and hygrometer for observing and recording, the disadvantage is the interpretation of data are inaccurate, can not be real-time monitoring, and the data cannot be automatic electronic processing. Through the use of Internet technology, the system integrates the embedded technology, sensor technology and remote transmission technology, to achieve the larger space humidity automatic monitoring, real-time display of curves, and corresponding control functions.

The sensor system design for digital temperature and humidity sensor [1], type SHT10, this kind of digital temperature and humidity sensor can be directly detected data is output using the digital quantity, check on the sensor before they leave the factory, the user does not need to check operation.

System composition

This system mainly consists of four parts, one is the information collecting part, use SHT10 digital temperature and humidity sensor of indoor temperature and humidity data acquisition, and data processing unit, used by the Atmel Corp's ATMEGA48PA as the main chip, the data transmission part, uses the RS485 serial bus standard, the fourth is the result of display unit, display and graphical display using the PC software for temperature and humidity. The system according to the environmental space size selection of node set series network structure, to realize the automatic monitoring of operating temperature and humidity multi node.

The hardware design

The main chip. In this system the main chip selected 8 bit AVR processor produced by Atmel Corp, this processor is the AVR enhanced RICS structure for low power 8 bit micro controller based on CMOS, AVR kernel has a rich instruction set with 32 general-purpose working registers, all registers are directly connected to the arithmetic logic unit, so that an instruction can be two independent registers to be accessed in one clock cycle, the system circuit diagram is shown in figure 1.

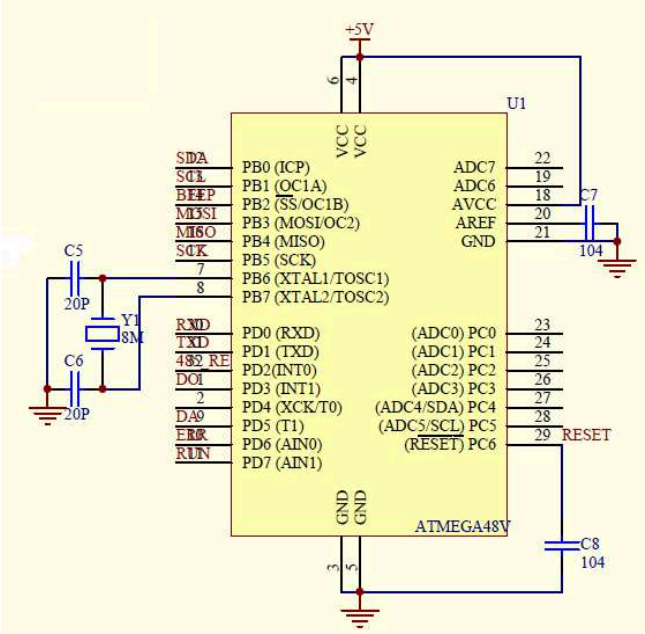

Fig. 1 The circuit diagram of the main chip

Temperature and humidity sensor. This system adopts the SHT10 digital temperature and humidity sensor as signal acquisition unit, the sensor has a free debugging, calibration free, the measurement resolution can be programmed, the ultra small package size etc.. The sensor and integrated temperature and humidity sensors, humidity measurement operation can be used for temperature compensation, and can provide high quality of dew point calculation function, high measuring accuracy, is a preferred equipment [2] a variety of temperature and humidity testing applications. The typical application circuit diagram is shown in figure 2.

The power supply voltage of the sensor is 2.4 to 5.5V. Sensor after power on, wait for the 11ms to cross the dormant state. No need to send during any instruction. Power supply pins (VDD, GND) can increase the capacitance of a 100nF, for decoupling.

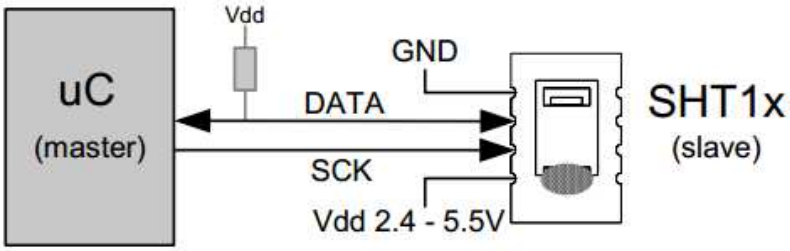

Fig. 2 Typical application circuit diagram

RS485 serial bus. Because the system needs to carry on the real-time monitoring of each node in a large space, the communication distance is long, therefore the RS485 bus mode for data transmission, RS485 a balance to send and receive difference, therefore has the ability to reject the common mode interference. RS485 uses half duplex mode, any time there can be only one point in the sending state, therefore, sending circuit required by the enable control signal. And RS485 can network constitutes a distributed system, the theory allows up to 32 parallel drive and 32 receiver, to ensure the reliability of data transmission, generally only connect the 8-16 node [3]. For temperature and humidity monitoring system of multi node, the node number is enough, circuit diagram is shown in figure 3.

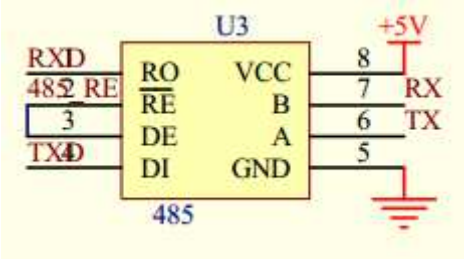

Fig. 3 RS485 circuit

Software design

Software design of temperature and humidity monitoring system mainly refers to the design of PC, the PC software for RS485 bus address settings, real-time changes and to monitor the indoor temperature and humidity through the graph, showing the effect of Figure 4 is shown in figure.

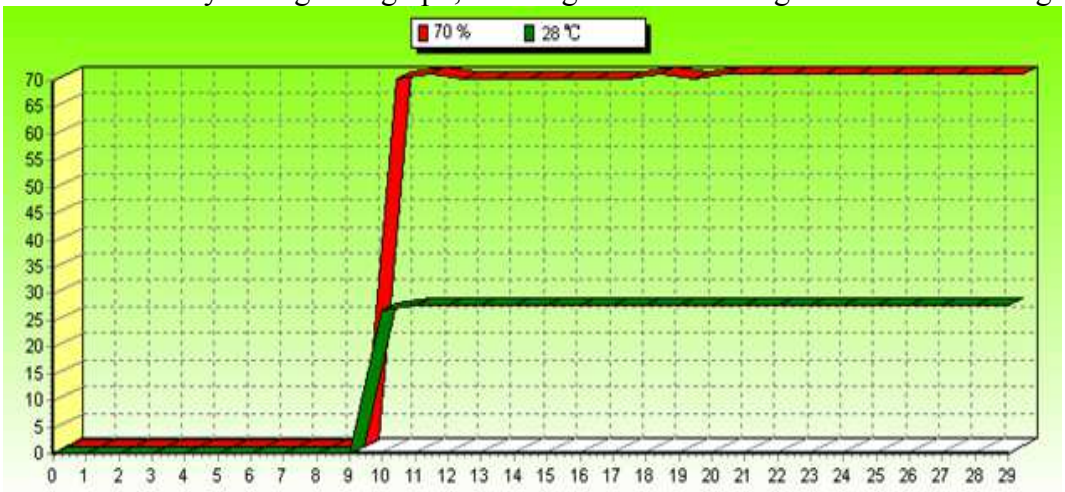

Fig. 4 Temperature and humidity state curve

The actual test result values in the software design program needs, by formula conversion mode is converted into real values, and displayed in the graph, the conversion code is as follows:

```
void SHT10_Cal(void)
{
   float RH_Lin;
   float RH_True;
   float Temp_C;
   Temp_C = -40.1 + 0.01 * temp;
   RH_Lin = -2.0468 +0.0367* duty + -0.0000015955 * duty *duty;
   RH_True = (Temp_C - 25) * (0.01 + 0.00008 * duty) + RH_Lin;
   if( RH_True > 100 ) RH_True = 100;
   if( RH_True < 0.01) RH_True = 0.01;
   temp = 10*Temp_C;
   duty = 10*RH_True;

}
```

Conclusion

This system after several tests, the operation performance of normal and stable, can view real-time temperature and humidity information of different nodes through the PC software, the humidity range from 20% to 90%, the precision is 0.3%, the temperature range of - 55 ° C to +125 ° C, precision is 0.1 ° C, system features such as:

(1) through the use of RS485 serial bus mode monitoring distance increases, can set the number of monitoring nodes in different regional indoor, so as to ensure the full monitoring of the environment.

(2) the system more flexible, only need according to the actual demand of new monitoring nodes, and the nodes can be connected in series by mode of access system.

(3) the system uses digital temperature and humidity sensor, improves the temperature and humidity monitoring accuracy, and can accurately display real-time curve.

(4) the PC software has the advantages of simple operation, the changes of temperature and humidity conditions can each node real-time monitoring, and display it in the most intuitive diagrams.

(5) the AVR kernel chip, 8 bit, low cost, system scalability.

The design of intelligent Home Furnishing system of Internet of things

Lei Wang*

School of Jianqiao University, Shanghai 201319, China

*gench_wl009@126.com

Keywords: The Internet of things, intelligent Home Furnishing, CC2530 chip, GPRS, ZigBee.

Abstract. Through the market investigation was designed based on the environmental monitoring system, intelligent control system and simulation system of security system, intelligent Home Furnishing system, this system uses CC2530 and sensors to build a ZigBee network, and realizes the remote monitoring through GPRS module, configuration of the PC software for the system, realized the function of intelligent furniture system through the actual test, that, the system is stable and reliable, practical.

Introduction

The Internet of things is called following the computer, the Internet, the third wave of global information industry. At present, many countries have spent vast sums of in-depth study, the Internet of things is a new technology system is composed of the fusion of several information technology into.

The so-called Internet by means of radio frequency identification (RFID), infrared sensors, GPS, laser scanners and other information sensing device, as agreed in the agreement, any objects connected to the Internet, the exchange of information and communication, to realize intelligent identification of objects in a network positioning, tracking, monitoring, don't and management [1] .

The key technology of things including RFID technology, sensor technology, wireless sensor network technology, intelligent technology and network communication technology etc.. RFID technology, also known as electronic tags, radio frequency identification, is a kind of communication technology, through the specific target radio signal recognition and to read and write data, between without recognition system with specific target to establish mechanical or optical contact. Commonly used with low frequency, high frequency, ultra high frequency, passive technology, RFID reader is divided into fixed and portable, the application of RFID technology is very broad, such as: library, access control system, food safety traceability [2].

Sensor technology is one of the basic technology of the Internet of things, perception layer in the IOT architecture [3]. As the basic unit of IOT, sensors in the network information collection level, can complete the data acquisition, has become the key to the success or failure of the physical network. Sensor is one kind of the signal measured specific, according to certain rules to convert a signal output device or devices available, to meet the information transmission, processing, recording, display and control requirements. The types of sensors and expansion, there is a common temperature sensor, humidity sensor, a pressure sensor, a light sensor, displacement sensor, ultrasonic sensor, gas sensor etc..

System architecture

Intelligent Home Furnishing called wisdom Home Furnishing or intelligent residential, said Smart Home in foreign countries. Approximate and intelligent Home Furnishing meaning of home automation (Home Automation), electronic family (Electronic Home, E-home), digital home (Digital Family), the home network (Networks for Home), intelligent home/building (Intelligent Home/Building), in China Hongkong and Taiwan areas, and digital home, digital Home Furnishing known method .

Generally speaking, intelligent Home Furnishing or intelligent residential (Smart Home), is based on the family home as a platform, the use of advanced computer technology, Internet technology, wireless communication technology, sensor technology and modern control technology, will be associated with Home Furnishing life of household electronic equipment (such as lighting, security, network appliances, information exchange) and other organic combined together, and the control and management of centralized on it, so as to create efficient, comfortable, safe, convenient, environmentally friendly living environment [4].

This system through the variety of the intelligent products and systems available on the market are analyzed, combined with the relevant systems have advantages and disadvantages, puts forward a solution of intelligent Home Furnishing system, the program will focus on four major subsystems, and the modular approach to the design and production of the whole, consists of four subsystems specific (1) environmental monitoring system; (2) the intelligent control system; (3) intelligent security system; (4) subsystem scene simulation. The so-called modular approach refers to the scheme will be intelligent Home Furnishing system as a pineapple, each intelligent Home Furnishing equipment as one of the pieces, the backbone of the four subsystem modules can be installed in accordance with the requirements based on the random selection of users, so you can Home Furnishing flexible intelligent system design according to the different needs of different users, in order to improve the system of intelligent Home Furnishing audience and user acceptance.

Four subsystems of intelligent Home Furnishing system is at the core of the program, the content of the relevant environmental monitoring system is introduced, based mainly is carries on the real-time monitoring of the home environment, the monitoring content can include temperature, humidity, light monitoring, dust monitoring, voice monitoring, and related monitoring may include single point monitoring and multi-point monitoring, can use a single sensor or multiple sensors for environmental monitoring data real-time statistics, and ultimately can conduct real-time broadcast by voice.

Intelligent security system is security, mainly refers to the use of the Internet of things technology security configuration on the family, to prevent theft, fire and other incidents, the specific prevention include fingerprint access control, door sensor, vibration sensor alarm, gas, fire, smoke alarm, infrared sensor, a human body induction, infrared curtain alarm, surveillance camera, voice control etc..

Intelligent control system mainly refers to the use of various control of all kinds of household appliances in Home Furnishing, specific control mode can include a universal remote control, Webpage mode control, mobile phone text messages and voice control etc..

Scene simulation system mainly refers to the joint operation of multiple functions, to realize the simulation of the scene, such as home mode, automatic turn off all lights, close the curtains when the user home; home mode, when the user back home, automatically open the curtains opened, lighting, background music etc..

Through the matching of the four subsystems, combined with pineapple Modular Intelligent Home Furnishing system model, the Internet of things technology applied to the intelligent Home Furnishing system, which provides a convenient, comfortable, intelligent living environment for users.

The hardware design

The main chip selection : This system takes into account the actual demand and cost when designing, we select STM32F103VCT6 as the micro controller, the chip is STM32F103 enhanced series, the use of high performance ARM Cortex-M3 32 bit RISC kernel, the frequency of 72MHz, built-in 256K cache, enhanced I/O port and connected to the two APB bus. Rich. STM32F103VCT6 can be connected with the two oscillator provides clock source for internal system, one is the external clock frequency for high speed, provide accurate for the system, because the chip of STM32F103 enhanced series, so the clock frequency is 72MHZ, the most typical of 8MHZ crystal, the frequency of the mode reached 9 the frequency of the requirements; second is the low external clock, the frequency of quartz crystal 32.768MHZ, used to provide precise calendar clock function for the system, and in the design

of the crystal is equipped with a battery, even if the accuracy of power down still can ensure the system clock. In addition, when designing the pin on the chip part was redefined.Chip design installation of reset circuit, the circuit design of the 14 pins of the chip is connected to a 10K resistor and a 104 capacitor complete reset circuit mainly by.

ZigBee wireless transmission module : ZigBee wireless transmission module in the intelligent Home Furnishing application widely, due to its advantages of flexibility, low power consumption and is widely used in the ZigBee chip, the CC2530 chip, the chip uses a system of the new generation SOC 2.4GHz, and also with the TI TI yellow gold unit ZigBee protocol stack and the Remo TI, you can supports the IEEE 802.15.4 standard, can provide a powerful and complete solutions in the ZigBee and ZigBee RF4CE remote control applications.

The GPRS module： The system requires the use of Short Message mode in the design of real-time information query and Short Message alarm, so the design increases the GPRS module, then chose Shenzhen Fangyuan company production of GU900D models, the model contains the DTU (data terminal equipment) function, and use the AT command to control, send for example use the AT+CMGS command can be Short Message. Circuit diagram is shown in figure1.

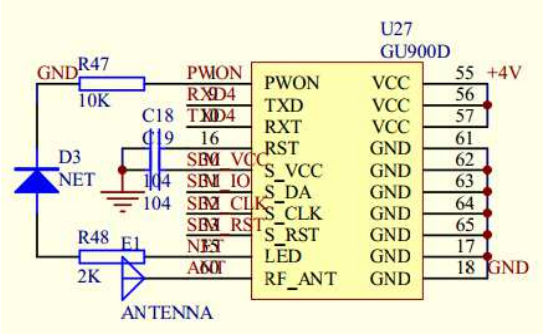

Figure 1. GPRS circuit

RS-485 bus module circuit design: This system when designing, system requirements of communication distance, so give up the traditional RS-232 bus interface and the RS-485 bus interface, the interface a balance to send and receive difference, therefore has the ability to reject the common mode interference. Bus transceiver coupled with high sensitivity, can detect voltage as low as 200mV, so the transmission signal can be recovered in kilometers. The RS-485 bus interface using half duplex mode, any time there can be only one point in the sending state, therefore, sending circuit shall be determined by the enable signal to control. RS-485 is used for the multipoint interconnections is very convenient, can save a lot of signal lines. The system uses the MAX3485 chip in RS-485 bus circuit design, the chip is required to power the 3.3V, transmission bandwidth is 10Mbps. Circuit diagram is shown in figure2.

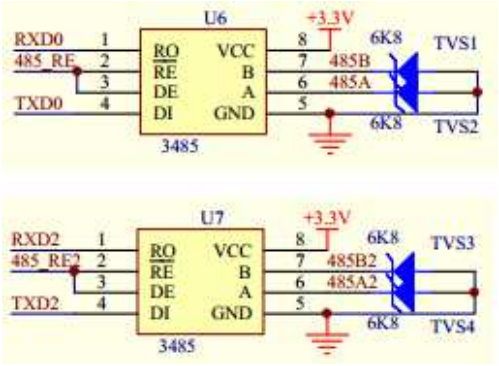

Figure 2. RS-485 bus module circuit diagram

Software design

The design of the control software of GPRS : Remote control in this system using the GPRS module of the system, through the use of Shenzhen GU900D model GPRS module and a radius of the

company production to complete the send and receive Short Message, first set the GPRS to Short Message mode must be in Short Message query, then the mobile phone SIM card into the GPRS module supporting the card slot, card send a message to the SIM through Short Message, specific code is as follows:

```
void send_sms(char * dh,char * smstxt) {
if (sms_from[0]==0) return;
      sprintf(send_buf5,"AT+CMGS=\"%s\"\r",dh);
      send_len5=strlen(send_buf5);
      mysend5();
   Delay(300000);
      sprintf(send_buf5,"%s\x1A",smstxt);
      send_len5=strlen(send_buf5);
      mysend5();
   Delay(300000);
}
```

The design of PC： The PC software mainly realizes the functions including real-time intelligent query Home Furnishing environmental information, including indoor temperature, humidity, brightness, and can change curve view environment, such as the opening and closing of the curtain by the control of the relay, the light open and close, and all kinds of home appliance control operation, and also can realize personalized customization by PC software, simulated operation of different users to achieve a different scene, the test results show that, the system can meet the demand of real-time monitoring and remote control of intelligent Home Furnishing system, realize the perfect combination of GPRS and ZigBee technology.

Conclusion

Through the analysis and Research on the networking intelligence Home Furnishing system, puts forward a set of intelligent Home Furnishing system based on four basic subsystem, the main control board, ZigBee module, GPRS module, various types of sensors as a basic hardware and software system design, PC, perfect control function of intelligent Home Furnishing system, after the completion of system development, through the long time experiment show that the system is running stable, easy operation, strong practicability, has higher application value.

Keywords: Delay Monitoring, Transmission, Intelligent substation

Abstract. In view of the current situation of the development of smart substation, this paper analyses the standing domain information sharing, information network transmission delay effects on substation protection system. Based on above, advances the information transmission time delay of the solution. This paper uses the accurate computing information packet switches reside within the delay ΔT and into the sampling value (SV) message, giving to protection device. Protection device dependent on local time benchmark, the use of MU inherent latency and link to reside the total delay ΔT reduction received multiple interval sampling data of the moment, on the basis of implementing protection control function.

Introduction

In Intelligent substation, the protection and control equipment are in need of the amount of multiple communication collected information, to complete the accident analysis, monitoring, control, data analysis, etc. Therefore, MU, protection and control equipment in substation requires accurate clock synchronization and accurate absolute time scale. MU output data synchronization in intelligent substation quality mainly depends on the following link: (1) master clock satellite signal; (2) the clock signal extension equipment; (3) MU synchronous signal connection; (4) to protect the sync signal connection

Ethernet communication technology due to its low cost, good openness, easy interface etc, obtained the rapid development in the field of network communication, more and more business data transmission based on Ethernet communication technology load. Based on Ethernet communications network layer adopts Ethernet switches as a general network transmission equipment, but as a result of general Ethernet switch based on store and forward exchange principle, theoretical analysis, the transmission delay of precise monitoring more difficult. So for the application of intelligent substation difficult.

Transmission delay in intelligent substation

The intelligent substation relay protection adopts the model of "network mining network jump" the biggest obstacle lies in the fact that span intervals protection must rely on external clock, to ensure the synchronization of sampling data, when loss of external clock or external clock malfunction, across space protection will run out. So have to delay uncertainty analysis.

Analog samples values cooperation unit and phase compensation and synchronous sampling, to the process bus transmission through Ethernet frame format SV, message transmission time delay in the transmission process of Td, namely the sending node application sends a message to the receiving node application receives the packet interval, involving different physical devices (such as Ethernet switches) communication processor working time delay and network transmission delay, packet delay t1 and t2 processing. Delay of message handling, mainly including the sending node communication processor protocol package delay t1 and receiving node communication processor to unpack the delay t2, associated with the software and hardware design and performance of communication processor, use appropriate microprocessor, real-time operating systems and protocols for efficient

encoding/decoding algorithm ensures the t1 / t2 values of certainty. Switches, for example, the delay of message handling, t1, fixed size depends on the switch chip processing media access control address table, virtual local area network (LAN), priority functions such as speed, general industrial Ethernet switch message processing delay no more than 10 mu s.

2）Delay the TSM message sent. Switches use a store-and-forward mechanism, after receive the complete data packet to forward data packets, and to support different rates port between the exchange of data message, keep high speed between the port and low-speed port work together. Store and forward the data packet delay caused by the TSM related to data packet length, data rate r L, can be said for the TSM = L/r.

3）Message transmission delay of tp. Physical device between the data message to close to the speed of light propagation in optical fiber links the time required for the tp, WAN (wide area network, WAN) cosco distance propagation delay of ms, and LAN (local area network, LAN) in the propagation delay, generally only several or dozens of mu mu s s, the proportion of the whole communication delay is small. Tp physical properties depend on the size of the link and the propagation distance, has nothing to do with the transmission of information, assuming that the physical distance between source port and destination port for D, the speed of light is c, transmission medium correction coefficient for k (about 0.65 k) in the coaxial cable, propagation delay can be represented as tp = D/(kc).

Delay calculation

"Network mining network jump" mode, the sampling data packet transmission depend on the switch, and the message transmission delay is uncertain in the switch, so when the external clock loses, protective device cannot judge whether the sampling data synchronization.

Through exchange report transmission time delay method can solve this problem, principle is the precise resides within the message on the switch delay Δ T and into the SV message, protection device dependent on local time benchmark, use MU inherent latency and link to reside the total delay Δ T reduction received multiple interval sampling data of the time, complete the sampling values of synchronous processing.

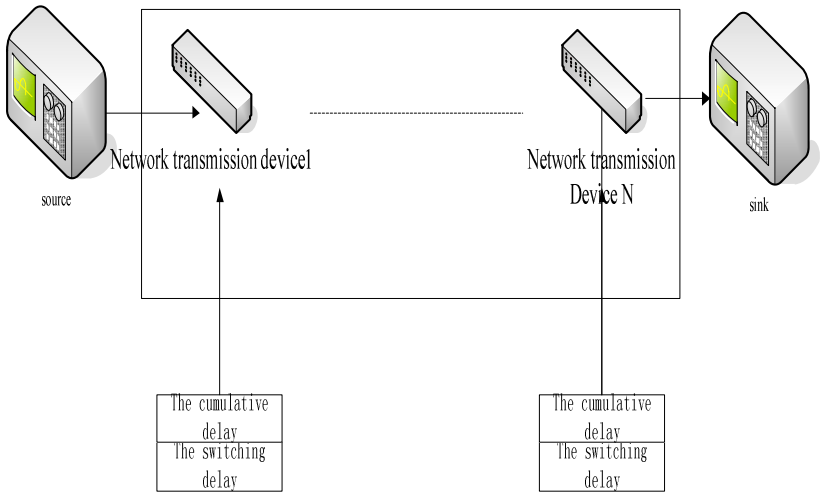

Fig. 1 Transmission system

Based on switched Ethernet network technology, application of the link layer communication mode, and there is higher demand for real-time data transmission of business data transmission system, as shown in figure 1, including source equipment, among a number of network transmission equipment and obtaining-information equipment, from the source device from the carrier Ethernet data frame message through all levels of the middle layer network transmission equipment, network transmission carrier equipment using Ethernet data frame packet link layer reserved bytes of storage

when extension store-and-forward delay at all levels, and obtaining-information end equipment through to get the information from the source to the obtaining-information accurate delay, so as to realize switched Ethernet in the link layer communication of accurate delay monitoring.

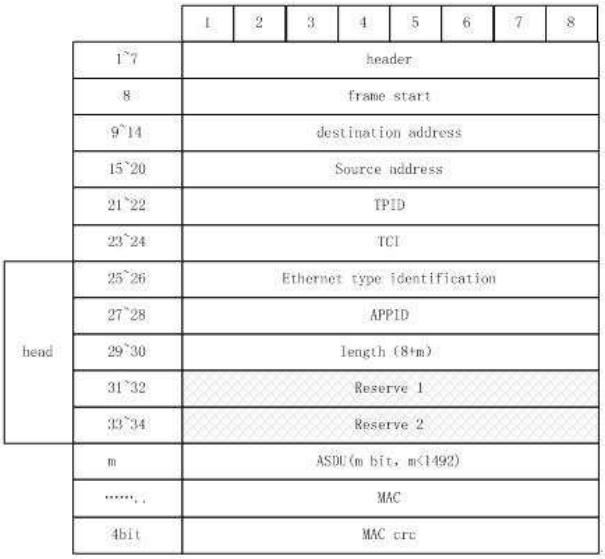

Fig. 2 Frame format

Ethernet link layer communication data frame format shown in figure 2, the 31 ~ 32 bytes and 33 ~ 34 for the Ethernet packet header reserved four bytes, in specific business applications, in do not break general definition, compatible with ordinary Ethernet, on the basis of data frame format, message to achieve accurate monitoring of transmission delay information, can be the proprietary defines four bytes, this is also one of the key points of this invention.

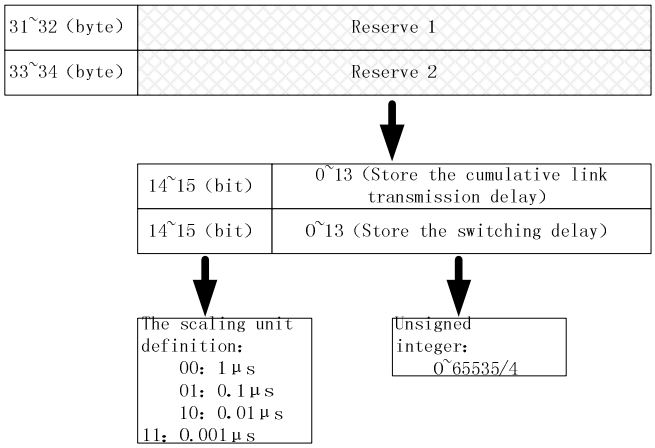

Fig. 3 Cumulative link transmission delay

Four bytes can be divided into two groups, respectively for MouJi/jump to store intermediate network transmission equipment of the cumulative link transmission delay (from the source to the level/jump all transmission delay between the transmission equipment accumulation) and dance at the corresponding level/transmission equipment switching delay (this value depends on the transmission equipment's data exchange mechanism, such as store and forward, or address passthrough, etc.), a detailed description is shown in figure 3.

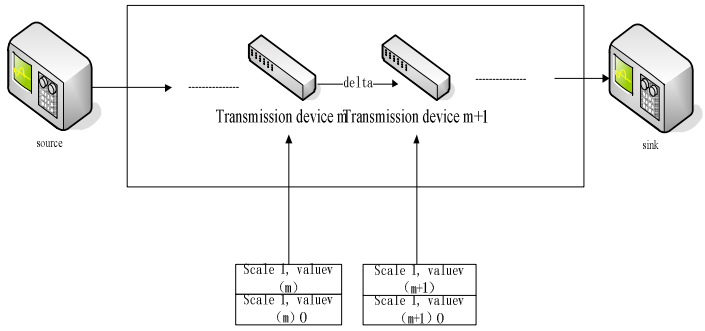

Fig. 4 Application system

In order to ensure the accuracy of transmission delay of storage, the invention adopts scale mode of two time delay of the deposit, concrete is: double byte high two type definition for scale, is divided into four kinds, representing 1 microsecond, 0.1 microseconds, 0.01 microseconds, 0.001 microseconds. After the double byte 14 for deposit after the scale of values, use unsigned integer way, value range of 0 ~ 65535/4.

Conclusion

In this paper, the information delay solution. This paper uses the accurate computing information packet switches reside within the delay Δ T and into the SV message, giving to protection device. Protection device dependent on local time benchmark, the use of MU inherent latency and link to reside the total delay Δ T reduction received multiple interval sampling data of the moment, on the basis of implementing protection control function.

Based on the information described in this article, therefore, delay the solution can be in a new generation of intelligent substation system application. According to station domain sharing information, realizes the fault points of fast, accurate and reliable isolation. Improve the performance of relay protection, in order to meet the requirement of large complex power grid safe and stable operation.

Keywords: Maximum power point tracking, Neural network, Photovoltaic cells

Abstract. detailed analysis of mathematical model, expounded maximum power point tracking (MPPT) control principle, then a improved constant voltage tracking of maximum power point tracking control based on GRNN neural network is proposed, this control strategy uses predicted voltage of GRNN neural network to instead of constant voltage, has be simulated in Matlab /Simulink, and result is this MPPT method can be more accurate compared to traditional control strategy.

Preface

Energy is a shield of our Social stability and economic development, and improves the quality of our lives. With the rapid population growth and urban modernization, meeting the energy demands of a big city becomes a formidable task. The world relies on oil, coal and gas for about 80 percent of its energy, but these non-renewable energy resources produce considerable pollution in process of using. More and more people are concerned about Solar energy due to its vast and easily accessible reserves, Study of MPPT control has become research hotspots in order to achieved higher conversion rate for turning light into electricity.

Analysis of Solar cell output characteristics

Photovoltaic cell is core research content of photovoltaic power generation system, the output characteristic of photovoltaic cells is nonlinear, this is because photovoltaic cell is greatly affected by the external factors such as strength of illumination and temperature, the following is the equivalent circuit diagram of photovoltaic cells[2].

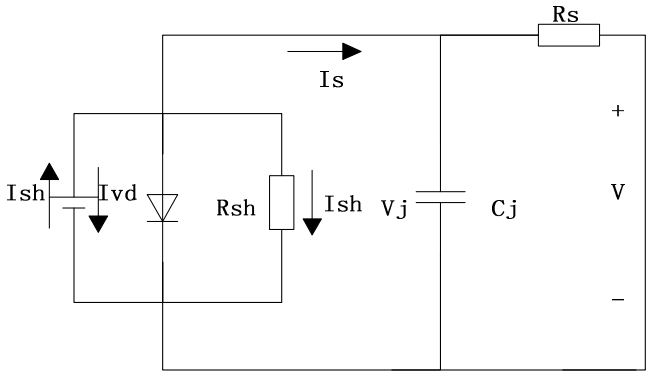

Fig. 1 PV equivalent circuit

In this figure, Rs is series resistor of circuit, its resistance is less than 1Ω, Rsh is parallel resistance of thyristor, it has bigger resistance value, Cj is junction capacitance, resistance of Rsh and Rs can be ignored in the simplified circuit. The simulation model is built in Matlab /Simulink and get output curve of photovoltaic cells through the simulation[1].

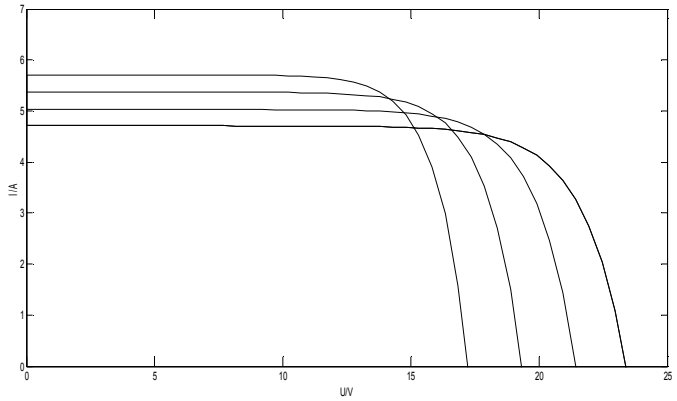

Fig. 2 I-V characteristic curve

I-V characteristic curve as shown in Fig.2, the working current of photovoltaic cells is stable at first, when the output voltage increases, output current is decreased and become zero eventually.

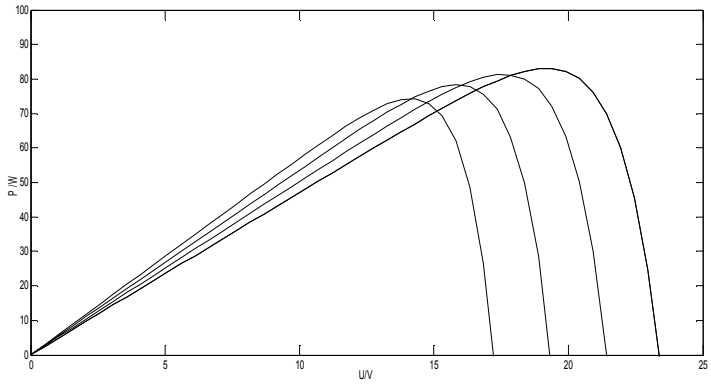

Fig. 3 P-V characteristic curve

P-V characteristic curve as shown in Fig.3, the output power increases as the voltage increases, and reaches a maximum value at a fixed voltage value, then output power is reduced when voltage increases continuously.

Based on the analysis above, we can conclude that the maximum power point of photovoltaic cells exists. In order to improve the efficiency of photovoltaic power generation, photovoltaic power generation always working at maximum power point is important[3].

Principle of MPPT

The output characteristic of photovoltaic cells is nonlinear, short-circuit current and open-circuit voltage are significantly affected by strength of illumination and temperature, the output power of photovoltaic system is unstable due to this reason. As is known to all, the external environment of photovoltaic cells changes quickly, in order to reduce the power loss and improve energy conversion rate, making adjustments according to this change is necessary. Even if strength of illumination and temperature remain unchanged, the output power will change as well due to variation in load, for this reason, to ensure photovoltaic power generation works at maximum power point, photovoltaic system and load cannot be directly connected.

According to relevant conclusion of circuit, when the output resistance of photovoltaic cells is equal to equivalent resistance, photovoltaic cells output maximum power. In real terms, equivalent resistance of household appliances is random, and internal resistance of inverter and storage battery will change in the process of using, these reasons account for load change of photovoltaic cells, so the principle of MPPT as follows:

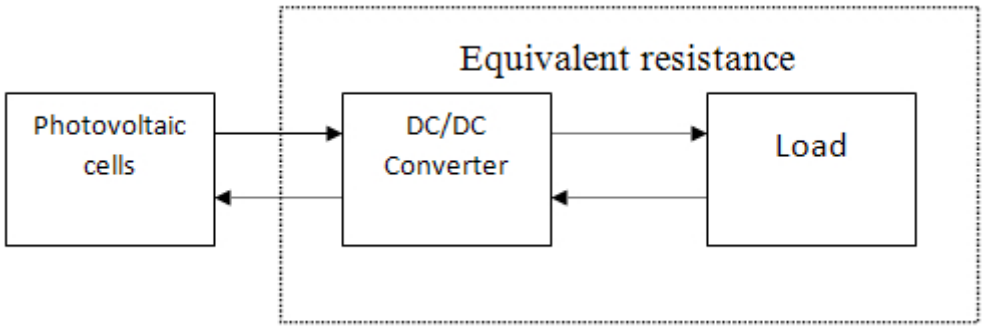

Fig. 4 PV system structure diagram

In Fig. 4, if DC/DC converter and load of photovoltaic cells is equivalent to resistance, according to theory of power electronics, output impedance can be changed by adjusting DC/DC converter duty ratio. The key of MPPT is adjusting DC/DC converter duty ratio by control strategy, when output impedance of photovoltaic cells and equivalent impedance are equal, photovoltaic power generation system works at maximum power point

MPPT control based on GRNN neural network

With the development of artificial intelligence, learning ability and predictive ability of artificial neuron was found, inputs and outputs of nonlinear system can be simulated by artificial neuron. So this paper presents MPPT control algorithm based on GRNN neural network, utilizes GRNN neural network to predict working voltage of the maximum power point. Using this predicted value to instead of the fixed voltage of constant Voltage Tracking will improve control accuracy.

Principle of GRNN neural network. GRNN is shorted for General Regression Neural Network, it is a new neuron structure proposed by Donald • F • Specht and based on nonlinear regression theory. GRNN neural network has fast learning speed and better predictive ability compared with BP Neural Network and RBF Neural Network. This neural network has only one adjustable parameter and less thresholds, and learns relying on sample in the whole learning process, so the influence of human factors is slight.

GRNN neural network and RBF neural network are similar in network structure, includes input layer, pattern layer, summation layer and output layer.

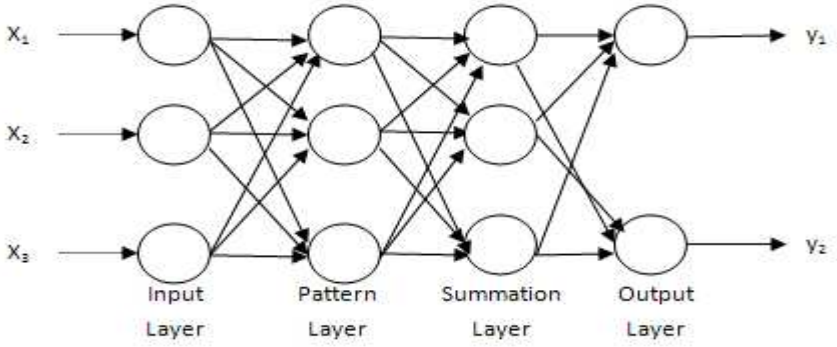

Fig. 4 Structure of generalized regression neural network

The number of input units is equal to the number of input variables, the control strategy mentioned in this paper has two input variables, one is temperature and the other is strength of illumination.

The number of pattern layer units is step with the number of learning samples, transfer function of pattern layer is as follow:

$$p_i = \exp[-\frac{(x-x_i)^T(x-x_i)}{2\sigma^2}] \quad (1)$$

In this formula, i=1,2,3……, x is input quantity, xi are learning samples of neural network.

There are two neurons in the summation layer, one is the sum of the output variable of pattern layer, and the formula is as follow:

$$S_1 = \sum_{i=1}^{n} p_i \quad (2)$$

The second neuron in the summation layer is the weighted sum of the output variable of pattern layer, and the formula is as follow:

$$S_2 = \sum_{i=1}^{n} p_i y_{ij} \quad (3)$$

The number of output units is equal to the number of output variables, there are only one output variable that working voltage of the maximum power point in this paper, transfer function of output layer is as follow:

$$y_j = \frac{S_2}{S_1} \quad (4)$$

Principle of MPPT control based on GRNN neural network. Here are several key steps to MPPT control based on GRNN neural network:1, Finding out the output voltage corresponds to different temperature and strength of illumination by the simulation waveform;2, Training GRNN neural network with the data obtained in step 1; 3, To replace the fixed voltage of constant voltage tracking with the trained neurons. This method uses neural network to forecast the optimum operating voltage, in order to change the output voltage , takes the difference between predictive voltage and the actual output voltage of DC/DC conversion circuit as the signal to drive PWM device, this PV system keep the maximum power output finally. In this paper, DC/DC conversion circuit is BOOST circuit, because BOOST circuit conversion is more stable and less energy loss than BUCK circuit.

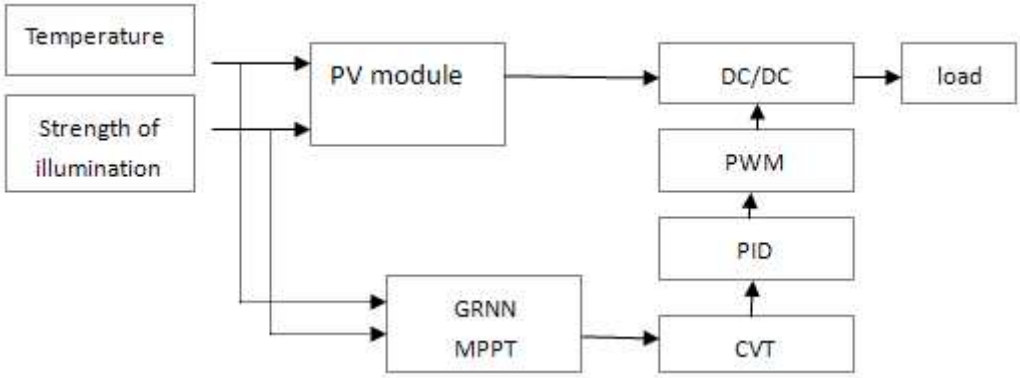

Fig. 6 Boost control principle with MPPT

Simulation analysis

Simulation research on MPPT control based on GRNN neural network, a simulation model was established in Matlab/Simulink, the simulation parameters are as follows: step is 0.01;the energy-storage capacitor is 0.005F; resistance R is 10Ω; inductance values of BOOST circuit are 6mH and 3mH ; spread value of GRNN module is 0.7.

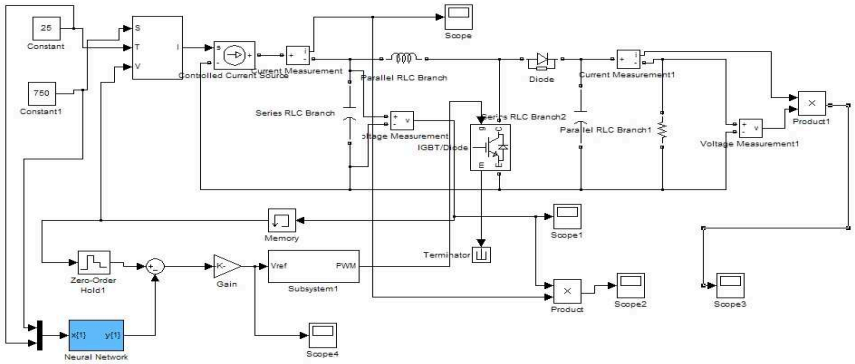

Fig. 7 Simulation model of MPPT based on GRNN

Ambient temperature is set to 20℃, simulation time is 2S; the input strength of illumination are 1000W/㎡ and 500W/㎡respectively, the output power curve of P&O is as follow:

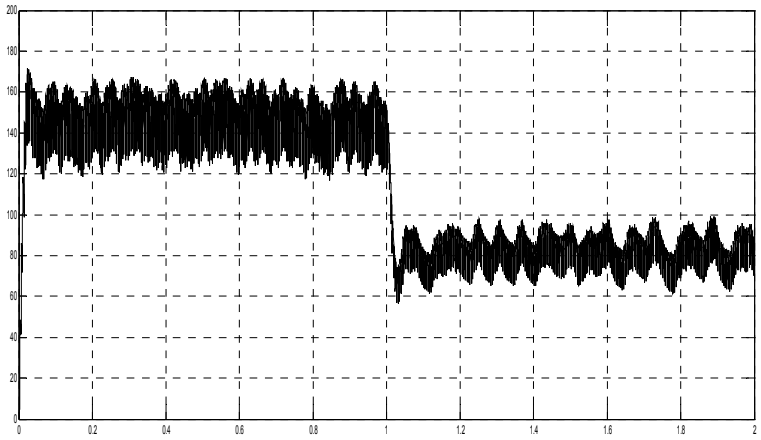

Fig. 8 Output power curve of P&O

Perturb & observe algorithm acts quickly, the time this control strategy spent on acting is less than 0.1s, but its shortcomings are obvious, the first one is waveform fluctuations in the whole control process, even action was completed. Fluctuations of output power waste a lot of energy and increases the burden of the hardware. Secondly, when external conditions change dramatically, MPPT cannot be finished quickly, as can be seen from the table, tracking performance of Perturb & observe algorithm is lower than the proposed control strategy.

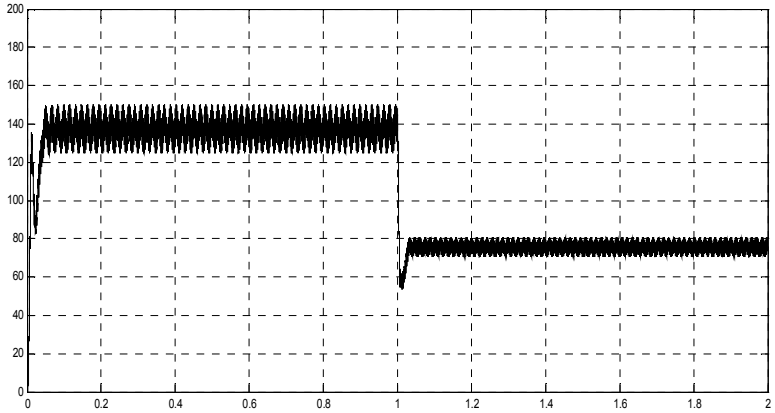

Fig. 9 Output power curve of MPPT based on GRNN

The above picture is the power output waveform of MPPT tracking control based on GRNN neural network, the power output waveform is more stable than Perturb & observe algorithm, and the efficiency of energy utilization is improved. When time is 1s, the strength of illumination changes, MPPT tracking control based on GRNN neural network can be fast-tracking, so the proposed control strategy is better than conventional MPPT control algorithm.

Conclusion

PV Simulation model was established in this paper, analysed output characteristic curve of PV cells, illustrated the principle of MPPT, proposed MPPT control based on GRNN neural network. At last through the simulation analysis, effectiveness of this Control strategy is proved. The proposed control algorithm has higher accuracy and stability, tracks quickly even the external conditions change.

Arrangement of sensor nodes for wireless sensor network in aquatic products breeding

Shi Bing, Xu Shoukun, Jiang Jianming

School of city rail transportation, Changzhou University, Changzhou, 213164, China

email: shibings@163.com

Keywords: sensor node; Data Analysis; Optimal arrangement

Abstract. In order to overcome the disadvantages of ccomplexity of monitoring systems, inconvenience of installation for equipment and wiring, high error rate of data transmission, the technology of wireless sensor network is adopted. Through analysis of pond water testing results on the space distribution of water environmental factors, and the number and location of the sensor nodes is determined based on the distribution law of key factors. Experiments show that the system has higher accuracy and stability.

Introduction

The scale aquaculture has become a major commercial aquaculture farming methods, and in aquaculture, accurate measure and control of dissolved oxygen, pH, salinity, temperature and other environmental factors are very important. Currently monitoring systems adopted in aquaculture mostly based on cable, all sensors are connected to the cable. The traditional way to build such a system will face many problems. While increasing the number of sensors, change of system parameters will be resulted in, and modifications of the upper application may even be brought. It will also lead to a large number of on-site connecting cable lines, increasing cost of installation and maintenance. The technology of wireless sensor network is introduced to replace traditional wired systems.The monitoring system is based on a new wireless multi-parameter sensor networks, the parameters data collecting by sensor nodes are sent to the sink node via wireless communication, and then the sink node share the data via a internet network. The arrangement of sensor nodes is the key to collecting the comprehensive and correct data. Study on the arrangement of sensor nodes will be valuable significantly.

System Structure

The system consists three parts: real-time monitoring unit, control and execution unit and wireless sensor network unit, system architecture is shown in Figure 1.

Real-time monitoring unit includes two grades: site monitoring center and remote monitoring center. There are three basic functions of site monitoring center: receiving transmission data from WSN sink nodes, processing data and controlling the work of execution unit, uploading data to remote monitoring center through GPRS. And there are also three basic functions of remote monitoring center: accepting data from site monitoring center through GPRS network, database support, providing WEB services. The upper and lower computers can both complete data inquire, data analysis and other work. And the unit can also provide messages to mobile phone users.

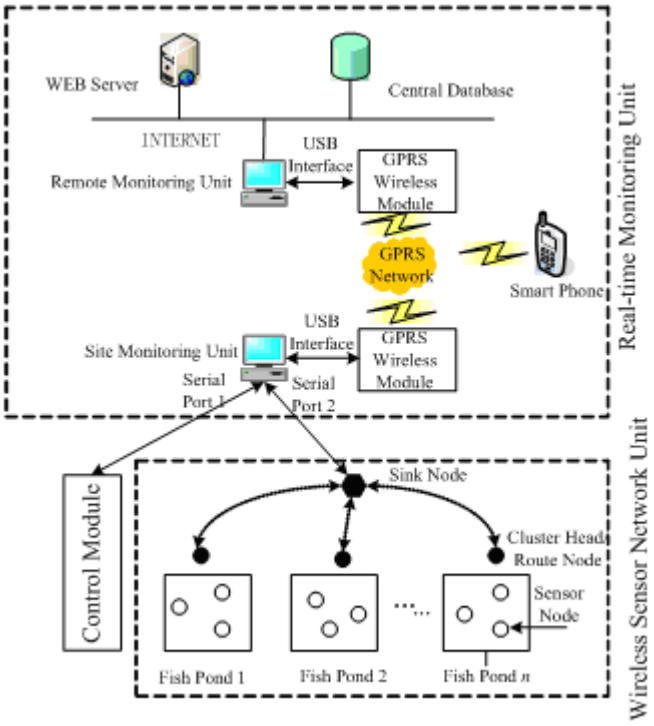

Fig.1. System structure

The upper computer of monitoring center can achieve functions such as data management, intelligent decision-making, statistical analysis of historical data, fault diagnosis, display, printing and output; and through image acquisition system, using computer image processing technology, the growth of fish in site aquaculture can be monitored real-timely, and beep in time when the fish die or in bad condition.

The control and execution unit is composed by actual hardware equipment, such as solenoid valves, transducers, relays and electrical switchgear. According to farmed fish species, growing season and other factors, the site monitoring computer determine the given values of optimal environmental factors through expert system, and send the values to the control unit processor via the serial port; the microprocessor will compare the values of environmental factors from site central computer with the given values, then give the corresponding control signals through appropriate treatment of control algorithm; control the execution unit such as frequency converters, solenoid valves, pump, pH pump; and complete the regulation tasks related to environmental factors; in order to achieve precise control of water quality parameters of the breeding pond.

Wireless sensor network unit is the basis of data transmission in this system, it is composed of a large number of sensor nodes, routing nodes and a cluster node. Sensor nodes are used to monitor the water environmental factors in each fish pond real-timely, and then convert the values collected by sensors to digital signals, and transmit these parameters to sink nodes in appropriate route traffic through wireless sending module, the values are such as temperature, dissolved oxygen content, pH, water level, and turbidity. At last, the data are transmitted to site monitoring computer by sink nodes through the serial port, and the uploading work is completed.

Sensor node arrangement

The arrangement for sensor node in crab pond has to take account of the actual size of the pond, water depth and construction materials. Therefore, spatial distribution of dissolved oxygen, temperature, and pH must be determined firstly at different location, and different depth. And then the arrangement for network nodes can be determined order to effectively achieve the purpose of optimization.

Environmental conditions:
Standard atmospheric pressure, ambient temperature 22 ~ 24 ℃, southeast wind 3 to 4;

Test Object:
Length of Pond: 150m, width of pond: 50m, depth of pond:1.5m;

Acquisition parameters:
Dissolved oxygen, temperature and pH value;

Sampling point:
Sampling points are shown in Figure 2.14, and each collection point away from the surface of the pond 0.3m, 0.6m, 0.9m, 1.2m and 1.5m at the sampling. The positions of sampling points are shown in Figure 2.

Test method:
Manually standard instruments are adopted.

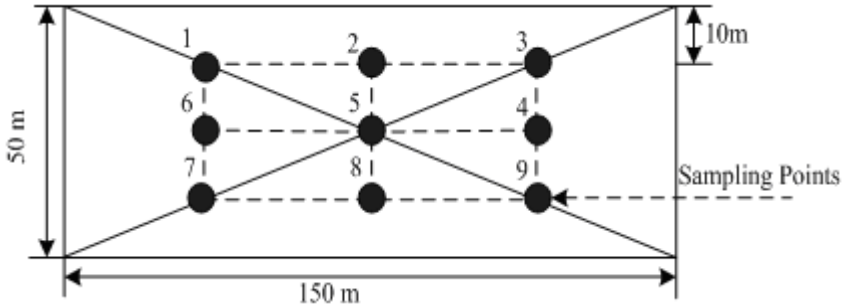

Fig.2. Distribution of sampling points

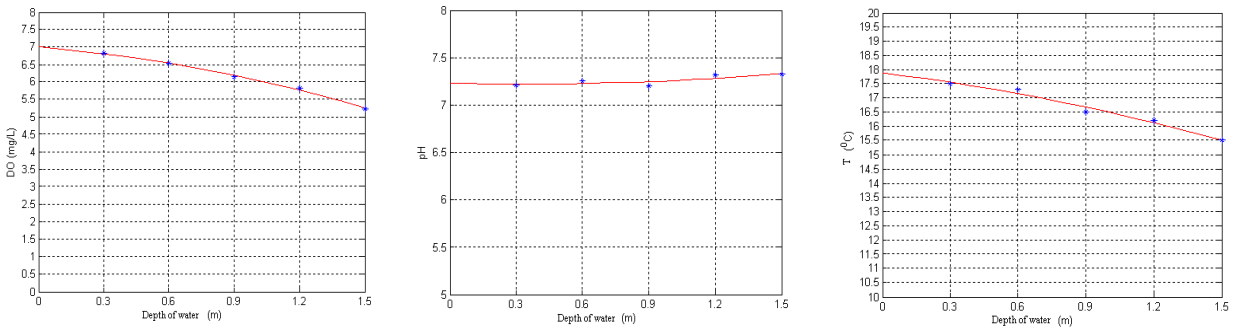
The data analysis from sampling points shows that: value changes of dissolved oxygen and temperature are little; however, in the horizontal direction the value changes are large. The value change of pH is significant both in the horizontal and vertical direction.

The curve of dissolved oxygen, temperature, pH and depth of water are show in figure 3.



(a) Curve of DO and depth (b) Cure of pH and depth (c) Cure of temperature and depth

Fig.3. Sampling curve

Test results

The test three ponds are three adjacent outdoor ponds with size of 150m × 50 m, and water depth of 1.5 m, standard atmospheric pressure, and ambient temperature 22 ~ 24 ℃. The sensor nodes work for collecting temperature data and sending then to the sink node, the sink node can display the data through its own extended LCD, and simultaneously upload the data to the control center computer via the RS232/RS485 circuit.

Table 2 Temperature testing data unit: ℃

Test Times	Standard Equipment Data	Sink Node		Computer On-site	Computer Remote	Error
		Data	Error	Data	Data	
1	21.0	20.8	-0.20	20.8	20.8	-0.20
2	23.5	23.4	-0.10	23.4	23.4	-0.10
3	27.0	27.1	+0.10	27.1	27.1	+0.10
4	30.0	30.3	+0.30	30.3	30.3	+0.30
5	33.0	32.8	-0.20	32.8	32.8	-0.20
Absolute Error			0.18			0.18

Table 2 shows that the data from node data center, on-site monitoring data and remote monitoring center are the same, and the error between data and data from standard equipment is within ± 0.3 ℃. The security and reliability of communications in the wireless sensor network are satisfied.

Conclusion

Through a lot of experimental results, the parameters characteristic of distribution in the horizontal direction and the vertical direction is determined and the sensor nodes are arranged appropriately based on the physical location.Experiments show that the system has higher accuracy and stability.

Keywords: Lightning protection business, Lightning protection devices(LPD) inspection, On-site data process, Mobile GIS technology

Abstract. As a most grievous meteorological disaster in the world, lighting calamity is destructive and could be inducement of fire explosion accidents. Lightning protection business mainly consists of lightning protection devices (LPD) inspection, lightning disasters authentication and lightning risk evaluation, for which on-site data gathering is indispensible, and the status in quo has common defects. Based on tablet-PC and mobile information technology, we developed a platform including such seven modules as system configuration, LPD inspection of existing buildings, LPD inspection of under-construction buildings, identification of lightning disasters, lightning risk assessment, location of inspected clients and location of inspectors. Mobil GIS technology and fast-developing method of forms were taken into use as key technologies. With its help, an promotion of facilitation, standardization and intellectualization of lightning protection business is achieved.

Introduction

As a most grievous meteorological disaster in the world, lighting calamity is destructive and could be inducement of fire explosion accidents. Society and the authority is laying higher attention on lightning protection and disaster reduction.

Inspection of lightning protection devices is indispensable especially for petroleum and chemical industry and places with high density of people. Evaluation of lightning-disaster risks is a growing business of lightning protection by assessing lightning risk of such places as major projects and hazardous areas, and by proposing rectification measures based on systematical analysis of lightning caused damages and casualty. Identification and investigation of lightning disasters is part of social management and important for settlement of insurance claim [1].

Maturity of tablet PC and WIFI make integrity, intelligence and standardization of business process above possible. As a result, utilization of intelligent terminal will improve lightning protection technical services quality and enhance authority supervision [2].

Status in Quo of Lightning Protection Business

Lightning protection business mainly consists of lightning protection devices(LPD) detection, lightning disasters authentication and lightning risk evaluation, for which on-site data gathering is indispensible, and the status in quo has common defects. Let's take SPD detection for example. It is undertaking growing responsibility and venture in attention of the society, and the problems are obvious as below. Firstly, randomness of detection items and technical process lead to lack of standardization, which is to say, an inspector may use different methods at different spots and even come to a converse conclusion for the same one inspected unit because of disparity of personal and subjective factors. Secondly, manual manipulation leads to lack of accuracy and quality control. For instance, the grounding resistance is usually the only value a detection report carries, while location, material and corrosion is not considered. In case of a lightning disaster, it is impossible to judge accurately the lightning protection devices are qualified or not, leading to a potential responsibility risk of SPD detection business. Finally, low efficiency of on-site inspections and inconvenience of documentary management come as a result of manual data input. On one hand, inspection data

inputting takes much time and repetitive hand work, on the other hand, carrying, handling and storage of massive paper documents is also a problem for quality control. Risk assessment and authentication of lightning disasters are facing the same dilemma. Unstandardization and randomness of business process comes up as an obstacle for efficiency improvement. Uniformity and automation of lightning business is in urgent need, and tablet-PC based system could solve the problem to a large extent.

Advantages of Tablet-PC

Application of tablet PC has exploded in recent years. Not just for casual use, tablets are also superbly powerful business tools, which is why more and more businesses are turning to tablets for their everyday IT needs. You can go places that normal computers can't, because they're as portable and accessible as clipboards, with integrated wireless networking. They're almost as light as clipboards too. Tablet PC could be well applied in lightning business for such reasons as below.

Firstly, lighter Than Laptops. The extremely lightweight and handy characteristics of tablet PCs as compared to laptops are definitely the biggest advantage. Tablet PCs can be easily tucked under the arm and moved from place to place even by teenagers [3]. Secondly, input personlization. As tablet PCs are functional with the help of the special digital pen or stylus like gadget, the handwriting of a person becomes the input [4]. This enables better personalization and value-addition to work-based input than possible with a touchpad or mouse. Thirdly, flat Working Surface. The form factor and convertible design characteristic of a tablet PC enables it to be laid flat on any working surface [3]. This facilitates better presentations, personalized interactions with people or ability to showcase work to others in any work setting.

Besides, multiple professional software and platforms are indispensible in lighting business. Tablet PC is competitive with ARCGIS(a professional geographic information system) , MATLAB(a professional scientific computation software) and alike in the environment of iOS, Windows or Android [5]. So that technical process could be smoothly carried out on-site.

Development of the platform and its key technology

System Structure

Data collecting & processing system based on tablet PC takes use of intelligent terminals for on-site data collection and process, and data collected is sent to lightning integrated business platform for further handling. Lightning protection technical service product is finally achieved and is distributed to regarding users in terms of internet or paper documents. Integration of mobile data collecting system and business platform is shown as Fig.1. Business tasks are downloaded from the platform by LAN or WIFI and technical and data support is guaranteed. After that, data collection, input and process is carried out via mobile terminal, which is sent back to the platform and filed in the database of lightning protection center. The database is stored in the demilitarized zone(DMZ) [6] [7], which builds a security area to protect the intranet. Intranet users could get access to such business as LPD inspection, risks assessment and lightning disasters analysis. Inspected users could also register and refer to business progress and technical support.

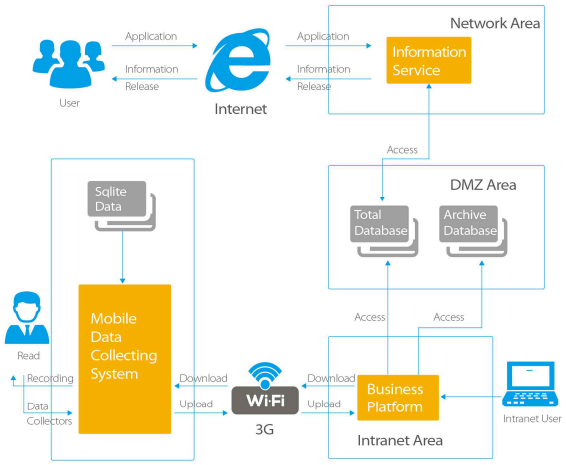

Figure 1. System structure

Key Technology

1) Mobil GIS technology: On-site inspection requires fast positioning and geographic information. Based on mobile internet and smart cellphones, mobile geographic information system(GIS) realizes offline maps, mobile positioning, mobile cartography and mobile office. It enjoys advantages as below.

a) Mobility: Installed on mobile terminals, mobile GIS could offer space information service by means of interaction with the server via WIFI communication anytime and anywhere.

b)Diversity of client terminals: Users have a wide range of terminals to choose, from laptops with strong calculation ability to PDA or smart phones of satisfying portability, which guarantee mobile GIS an open and Scalable platform.

c)Timeliness: Information could be processed and sent to clients without delay by help of positioning devices and internet [8].

2) Fast-developing method of forms: There are massive forms to handle in lightning business. Efficiency will be relatively low by use of traditional forms developing methods. However, based on the fast-developing method, different kinds of forms and menus could be generated automatically and visibly [9]. Patterns could also be deployed flexibly. Structure of the fast-developing method is shown as Fig.2.

The form designing module consists of the following four submodules: visual programming, forms mappings, XML release and Engine access interfaces. The form engine module includes such submodules as forms management, data process, O-RMapping and reports management. Reports output module is for forms inquiry, data statistics and forms display.

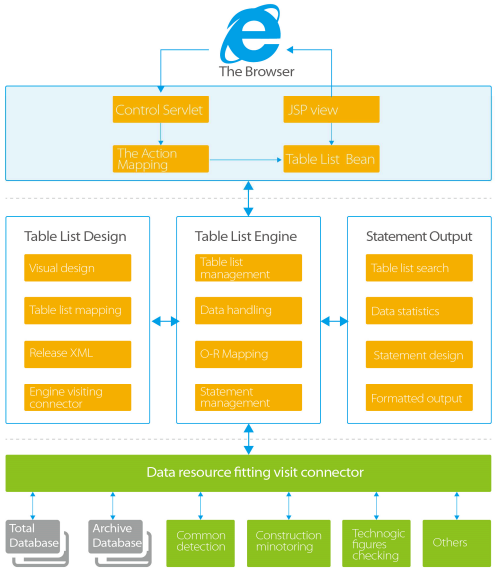

Figure 2. Structure of forms fast-developing method

Functional modules

Mobile LPD inspection system consists of the following seven modules: system configuration, LPD inspection of existing buildings, LPD inspection of under-construction buildings, identification of lightning disasters, lightning risk assessment, location of inspected clients and location of inspectors. Its functional structure is shown as Fig.3.

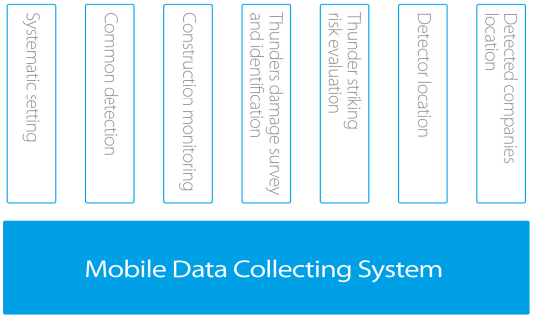

Figure 3. Functional modules of the platform

1) System configuration

System management is the main function of system configuration module, including parameters settings, personal management, authority settings, instruments management, standards documentation, clients' information and accessories, with which lightning protection rank, protection domain of a lightning rod, power resistance, impulse resistance, security distance, distribution of electro-magnetic field could be calculated.

2) On-site LPD inspection of existing buildings

According to the standard GB-50057(2010), lightning protection devices of existing buildings should be inspected annually, and semi-annually for explosion-hazard environment [10]. Meanwhile, surge protection devices (SPD) of low-voltage distribution system and signal system should also be inspected to avoid damage of electronic devices caused by lightning impulse and inductive surge.

This module includes such submodules as tasks download, current tasks, input of clients' information and on-site inspection data, auxiliary drawing, hand signature and inspection results upload. The process structure is shown as Fig.4.

First of all, an inspection task is downloaded via tablet PC, including inspection forms, clients' information and inspection history. Secondly, inspection information is completed in case of defective preliminary information. Thirdly, complete the inspection form and sketch map, marking location of the inspection spot, inspection value and further information alike. After that, lightning protection rank, protection domain of a lightning rod and electro-magnetic field intensity could be calculated based on data process and analysis. Then, the inspector will communicate with the client who will sign the report to guarantee validity of the inspection result. Finally, inspection forms and results will be uploaded to the server of lightning protection center.

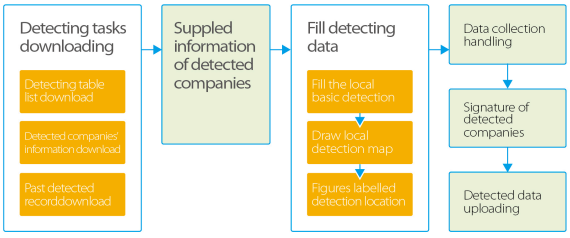

Figure 4. Process of On-site LPD inspection of existing buildings

3) On-site LPD inspection of under-construction buildings

LPD inspection of under-construction buildings is an approach of quality control of direct and inductive lightning-hit protection devices by inspecting each step during construction.

This module includes the following five submodules: tasks download, current tasks, input of clients' information and on-site inspection data, auxiliary drawing, hand signature and inspection results upload, which is similar to that of LPD inspection of existing buildings.

4) On-site inspection of lightning disasters authentication

The main function of On-site inspection of lightning disasters authentication is to analyze the reason of suffering lightning, conclude the main feature of lighting disaster and put forward effective protection instructions through the survey of lightning disaster site, lightning disaster monitoring analysis and late data reduction. The function of on-site inspection of lightning disasters authentication includes detection task downloading, detection information record, assistant drawing, detection recording uploading.

5) On-site inspection of Lightning Risk Assessment Site

The main function of lightning risk assessment business is a aggregate risk calculation in extent of casualties, property loss and injury according the analysis of lightning and disaster feature. At the same time, it is a evaluation methodology that offering constructive opinions for site selection of construction project, distribution of function division and determine of lightning category and protection measure.

The function of lightning risk assessment site detection includes detection task downloading, detection information record, assistant drawing, and record uploading. Lightning risk assessment site detection is mainly completing data gathering of lightning risk assessment site by using tablet PC.

6) Mobile positioning

Mobile positioning system consists of both inspectors positioning and clients positioning. The former one could be used to supervise inspectors' presence and the other one could be used for driving route guidance.

Functional modules

Let's take gas station as example of the application of lightning protection detection using mobile data collection system in tablet PC.Testers should download work tasks through a tablet computer first and query the current task. All of current tasks in the tablet PC should be shown in the calendar. Click on the calendar date, the detailed task for the day will be shown at the bottom of the screen in a table format. Click on a particular detection task inside the table, a detailed content will be shown. Detailed contents have three modules: the basic information about inspection unit, detection of basic information, detection of image information. Lastly, fill the detailed content in the corresponding module based on the situation.

As is shown in Fig.5, the sketch map is drawn according to the practical conditions. Detail abstracts and inspection values are added to the platform, and photos could also be taken on-site. Inspectors and administrators could have a comprehensive view of the inspection condition. Meanwhile, visualization input of inspection data offers an easy access to inspection value and other information.

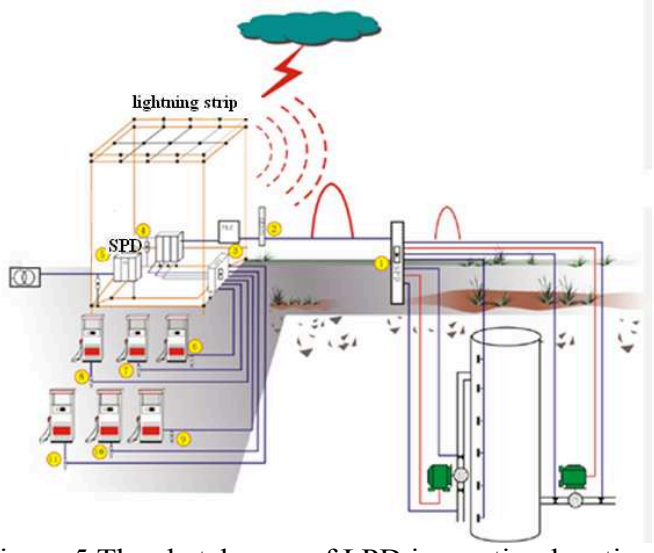

Figure 5.The sketch map of LPD inspection location

Conclusions

Based on tablet-PC and mobile information technology, we developed a platform including such seven modules as system configuration, LPD inspection of existing buildings, LPD inspection of under-construction buildings, identification of lightning disasters, lightning risk assessment, location of inspected clients and location of inspectors. Mobil GIS technology and fast-developing method of forms were taken into use as key technologies.

Mobile data collecting system contributes to standardization of LPD inspection business, avoiding massive repetitive input of original data. Besides, better efficiency could be achieved by promoting calculation and data process ability with help of tablet PC. Image manipulation and photographing function contributes to recapitulation of on-site inspection work, which could help monitoring service quality for administrators, and the sketch map generation module offers a much more convenient method to draw a sketch map on-site. Combination of LPD inspection business and information technology gives an promotion of its facilitation, standardization and intellectualization.

Keywords: GM (1, 1); accident; prediction; mining safety; MATLAB

Abstract. According to the grey theory, in order to predict and prevent accident effectively, the paper built a grey model and forecast the mine accidents in china in 2013 based on the statistics of mine accidents happened in China during period from 2007 to 2012. MATLAB was used to write procedure code of GM (1, 1) and empirical verification follows. The prediction results show that if high accuracy goes with the precision of the calculable model, which could be used to provide the basis for decision making to the safety production management practices in China. This case study indicates that GM (1, 1) plays an important role in mine safety management.

Introduction

Due to the high-risk of mining industries, the safety accident is easily to happen with serious consequences. Prediction and analysis of accidents will play a warning role on accident prevention work to improve energy industry. The GM (1, 1) model [1] was established on the grey system theory, which can be used to make a short period forecast line by a part clearly, part unclear with uncertainty sample. According to statistical data mining safety production accidents in China from 2007 to 2012, the total number of safety production accidents in mining industry is predicted by using the GM (1, 1) model and MATLAB software. It confirms that the GM (1, 1) model can be used to predict safety production accidents. And this provides a scientific theory basis for government, enterprises or relevant department to make a safe production management and decision.

The establish principle and method of the Grey GM (1, 1) model

The grey prediction theory. The grey system theory was created by Professor Deng Julong in China in 1982[1]. It has become a new cross discipline. In general, it is called the grey prediction which was predicted by the GM (1, 1) model. In particular, it must be predicted using the grey theory after the related test. The grey prediction test[2] includes: a. data inspection. b. The model test. c. Prediction test. The extrapolated reliability would be studied on the models.

Data feasibility test. The feasibility must be tested on the level of the original sequence by using data preprocessing method, including the translation method, the sqrt method, the logarithm method, the strengthening and weakening operator method.

A. Time series data consist of known accident data are represented by the formula. $x^{(0)}(\mathrm{n})$ is the accidents data in the annual year n.

$$\mathrm{x}^{(0)} = \left(x^{(0)}(1), x^{(0)}(2), \cdots, x^{(0)}(\mathrm{n})\right) \tag{1}$$

B. The accident number columns, $\sigma_x^{(0)}(k)$, is a accidents number ratio of between the previous year and the next year. as follows:

$$\sigma_x^{(0)}(k) = \frac{x^{(0)}(\mathrm{k}-1)}{x^{(0)}(k)}, \quad k = 2,3,\cdots, \quad n \tag{2}$$

$\sigma_x^{(0)}(k)$ is a level of the original accident sequence $\mathrm{x}^{(0)}$ in the annual year k.

The level sequence of the accident sequence was calculated by (1) (2):

$$\sigma^{(0)} = \left(\sigma^{(0)}(2), \sigma^{(0)}(3), \cdots, \sigma^{(0)}(n)\right) \tag{3}$$

C. It was tested whether all levels were belonging in the admissible covering area. If all levels were belonging to the admissible covering area, the accident sequence could be predicted by GM (1, 1) model. Otherwise, it needs a transform process to make the accident sequence belonging in.

$$\sigma_x^{(0)}(k) \in \left(e^{-\frac{2}{n+1}}, e^{\frac{2}{n+2}}\right) \tag{4}$$

D. Translation transformation: $y^{(0)}(k)$ is the accident data after transformation for the annual year k. c is a selected constant. $\sigma_y^{(0)}(k)$ would also be got. It should be satisfied to the requires of equation (4).

$$y^{(0)}(k) = x^{(0)}(k) + c, \quad k = 1,2,\cdots, \quad n \tag{5}$$

$$\sigma_y^{(0)}(k) = \frac{y^{(0)}(\mathrm{k}-1)}{y^{(0)}(k)}, \quad k = 2,3,\cdots, \quad n \tag{6}$$

The establish of the GM (1, 1) model [3]

A. $y^{(0)}$ was the initial sequence of the accident data.

$$\mathrm{y}^{(0)} = \left(y^{(0)}(1), y^{(0)}(2), \cdots, y^{(0)}(n)\right) \tag{7}$$

B. $y^{(1)}$ would be got by making one cumulative process on $y^{(0)}$.

$$\mathrm{y}^{(1)} = \left(y^{(1)}(1), y^{(1)}(2), \cdots, y^{(1)}(n)\right) \tag{8}$$

Above, $y^{(1)}(1) = y^{(0)}(1)$; $y^{(1)}(k) = \sum_{j=1}^{\mathrm{k}} y^{(0)}(j), k = 2,3,\cdots,n$.

C. $\mathrm{z}^{(1)}$ would be got by making a mean on $y^{(1)}$.

$$\mathrm{z}^{(1)} = \left(z^{(1)}(1), z^{(1)}(2), \cdots, z^{(1)}(n)\right) \tag{9}$$

Above, $z^{(1)}(k) = 0.5y^{(1)}(k) + 0.5y^{(1)}(k-1), k = 2,3,\cdots,n$, $y^{(1)}(1) = y^{(0)}(1)$.

D. The grey differential equation of the grey prediction model would be got. If the variable k is considered as a continuous time variable t, $y^{(1)}$ can be regarded as a function of the time t, as $y^{(1)} = y^{(1)}(t)$. Then the white differential equation of the grey GM (1, 1) also can be got.

$$y^{(0)}(k) + az^{(1)}(k) = b \tag{10}$$

$$\frac{dy^{(1)}}{dt} + ay^{(1)}(t) = b \tag{11}$$

E. The least square solution can be obtained by using the least square method. B is a data matrix. Y is a data vector.

$$u = (a,b)^T = \left(B^T B\right)^{-1} B^T Y \tag{12}$$

Above, $B = \begin{bmatrix} -z^{(1)}(2) & 1 \\ -z^{(1)}(3) & 1 \\ \vdots & \vdots \\ -z^{(1)}(n) & 1 \end{bmatrix}$ $\mathrm{Y} = \left(y^{(0)}(2), y^{(0)}(3), \cdots, y^{(0)}(n)\right)^T$.

F. The value of a and b could be obtained by using the solver of the grey differential equation (10). Then the prediction model equation would also be obtained.

$$\hat{y}^{(1)}(k+1)=\left(y^{(0)}(1)-\frac{b}{a}\right)e^{-ak}+\frac{b}{a};k=1,2,\cdots,n,\cdots \tag{13}$$

G. The estimate restore value of the original data, $\hat{y}^{(0)}(k+1)$, would be got by making a lago on $\hat{y}^{(1)}$. Finally, the simulation sequence can be obtained.

$$\hat{y}^{(0)}(k+1)=\hat{y}^{(1)}(k+1)-\hat{y}^{(1)}(k),k=1,2,\cdots,n,\cdots \tag{14}$$

Test on the accuracy of the model

The prediction model can be used, only if it passed the accuracy test. The quality of the model can be evaluated by using the model accuracy grade. It shows in table.1.

Table.1 The accuracy grade

Critical value	A	B	C	D
Relative error/ $\Delta 0$	0.01	0.05	0.10	0.20
Correlation degree/R0	0.90	0.80	0.70	0.60
The mean variance ratio/C0	0.35	0.50	0.65	0.80
Small error probability/P0	0.95	0.80	0.70	0.60
The evaluation result	Excellent	Qualified	Reluctantly qualified	Unqualified

Forecast applications

According to the state administration of work safety dispatch center statistics 2007-2012 domestic mine production safety accidents month distribution, distribution of accident year results is got and is shown in table.2. The number of domestic mine production safety accident for 2013 was forecasted.

Table.2 The annual distribution of domestic mine production safety accident in 2007-2012

Year	2007	2008	2009	2010	2011	2012
Accident	294	233	194	153	130	106

The predicted results were calculated by mathematics MATLAB programming and prediction model run data in table.3.

Table.3 The results of actual cases of GM (1, 1)

Year	$\mathbf{y^{(0)}}$	$\hat{y}^{(0)}$	ε	Δ	$\overline{\Delta}$	R	C	P
2007	294	294	0	0	0.0096	0.9985	0.0313	1
2008	233	232.7	0.3	0.0012				
2009	194	191	3	0.0155				
2010	153	156.6	-3.6	0.0235				
2011	130	128.5	1.5	0.0115				
2012	106	105.4	0.6	0.0057				
2013	—	86.5	—	—	—	—	—	—

Comparison with table.1, the model was tested, the relative error is less than 0.01, correlation is greater than 0.90, the mean square error is less than 0.35, a small error probability is greater than 0.95, the model determines the accuracy of grade level, excellent performance prediction, forecasting results with higher reliability. And the domestic mining production safety accidents predictive number is 86.5 in 2013, the actual number will be close to this data. The domestic mining production safety accidents decreasing trend, but the number of accidents is still at a high level.

Conclusion

The quantity of Safety production accidents reflects the level of safety operation. The total accidents were obtained by statistics. It is a typical Gray features. The accidents quantity could be highly predictive with less data by using the grey GM (1, 1) model.

The results show that security in our country is getting better; the safety production accident only is about 87 in mining industry in 2013. It has a great significance to the safety management work by using a scientific and reliable method to make an accurate prediction.

A production planning and scheduling process study based on dynamic information feedback

Qing Yang, Yanhua Ni

Industrial engineering and logistics engineering of Shanghai Jiaotong University, Shanghai 200240

Keywords: dynamic information feedback, multi-objective decision, scheduling rule, high resolution management

Abstract. Many factories usually can't use the production scheduling plan generated by some software directly, such as ERP and MES. Two main reasons are founded, one is the fixed parameter and data used in the planning and scheduling process; the other one is lack of Ability to respond to the dynamic production environment. This paper tries to improve the plan by using the dynamic information feedback and experience from workers, and a test states it is helpful in the daily work.

Introduction

Among all the production activities in the factories, making a good production plan is a critical step, because a good plan can not only satisfy the clients' requirement, but also ensure the production smoothly [1,2]. Nowadays most factories are using some software to make the production plan, such as ERP and MES. However, there are some shortages in the above two main software, the ERP system weaken the production scheduling module and the data monitoring and tracking module function in the shop floors[3], the MES system has made up the above two shortages of ERP systems, but the two software always can't work cooperatively[4,5].

This paper has done some research in some process industrial firms, two main typical problems are founded in their production plan. Firstly, some parameters in the software is relatively fixed (such as lead time, economic lot size and process route), which can't reflect the real dynamic production environment, the production plan generated by the software needs to be adjusted by experienced workers before used. Secondly, the actual production planning and scheduling process is a process of multi-objective constraint negotiation process, as the production environment changes, the objective and constraints of production plan is changing. The existing system can't adjust the objective and constraints according to the dynamic information. Finally, the result is that the workers have to collect the dynamic information they need from the shop floor, and adjust the production plan.

In order to make a good production plan, it is necessary to study how to improve the parameters and the production plan by using the dynamic information. In the latest researches, Professor Huang is doing the comprehensive research about using the RFID technology to improve the production, not only the material management, but also the production process in the shop floor [6,7,8,9]. By using this advanced technology, it is easy to obtain sufficient dynamic information. However few papers pay attention to improve the existing production planning methods by using the dynamic information feedback, Peter Cowling develop a general framework for using real time information to improve scheduling decisions [10]. So, Based on the situation of a real firm, this paper makes a further research to improve the parameters and the production plan by using the dynamic information. The following articles comes as five parts: part 1 illustrates the real problems founded in the firms; part 2 presents the new planning and scheduling framework; part 3 studies the method of dealing with the dynamic information; part 4 is a case study; finally the conclusions are presented in part 5.

Problem description

This paper makes an extensive investigation in a firm, which is producing the special lubrication oil. The existing planning and scheduling process are divided into three steps (Fig.1). Firstly, the ERP software generate monthly production plan by using some data, such as product demand, and economic production lot. Secondly, dealing with the monthly production plan and some fixed data, the MES software makes the weekly scheduling plan. Finally, the experienced workers adjust the plan according to the dynamic information and their experience, which is the most important.

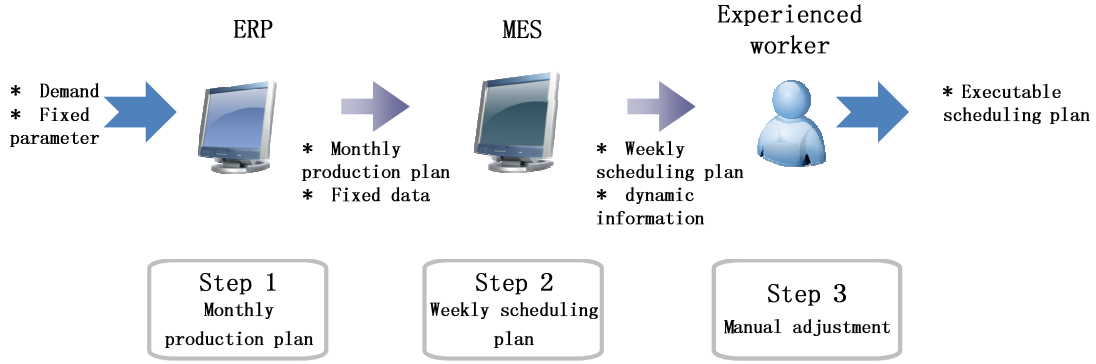

Fig.1 The existing production planning and scheduling process

The main problems in the existing process could be concluded into three aspects: Firstly, because of the fixed parameters (such as economic production lot), the monthly production plan generated by the ERP can't reflect the real production situation, and misleading production; Secondly, the fixed data (such as the processing time) may easily make the weekly scheduling plan fail in the execution phase; Thirdly, although experienced workers could adjust the plan, but they can't ensure that all the adjustment is the best.

Planning and scheduling framework

Given the above three main problems, A new planning and scheduling framework is proposed (Fig.2). As described in figure, the main Characteristics of the new framework are followed:

On the one hand, real time data are used to optimize the fixed parameters and data in the ERP and MES. For example, in the process of planning, the economic production lot (EPL) and processing time are the key factor for this firm. So, real time data should be used to optimize these two factors primarily. But different period of real time data is for different use. The EPL is used in the monthly production planning, and the relative long-time accumulation of real time data is more useful, however the processing time is varied according to the environment, workers, and other factors, the relative short-time accumulation of real time data is more useful. Part 3 study the key method in the real time information processing.

On the other hand, real time information could also help worker to handle the failed plan. In the real operation, different information could be processed with different rules, and these rules always can't be programmed into the software. So it is very necessary to build the clear or fuzzy connection between the real time information and the rules, when a certain activity is carried out, a relative responded rule could be picked immediately. Part4 presents the rules-based the scheduling process.

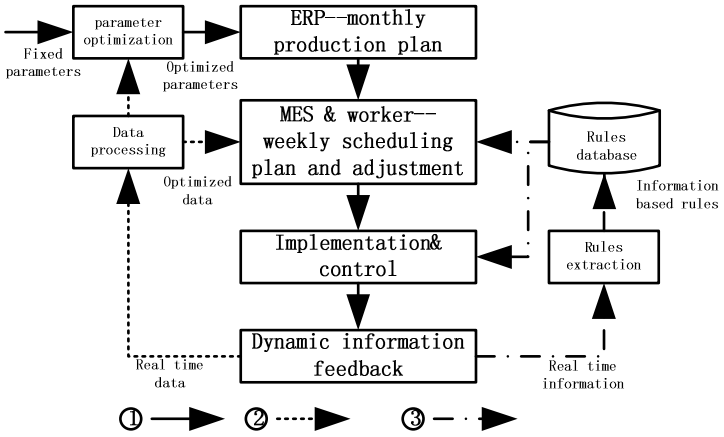

Fig.2 The new planning and scheduling framework

Dynamic information handling

For the best use of the real time information, different time-period of information should be processing with different method. Because the statistical methods are extensively used [11], so it is relatively easy to find the changing rules for the long-time accumulation of data, and the certain affecting factors in the short-time accumulation of data. This paper would not present the basic methods to process the data, and pay the main attention into how to use the processed data.

Building the connection between the data and rule is the key, a quadruple form $\langle S, A_t, V, R \rangle$ is proposed[12], $S = \{s_1, s_2, \ldots, s_n,\}$ is the finite set of production factors which can be collected data in the shop floor; $A_t = \{a_1, a_2, \ldots, a_m,\}$ is the finite set of attributes of production factors; $V = \{v_1, v_2, \ldots v_m,\}$ is the range of attributes, and v_i could be described by $\left[\underline{v}, \overline{v}\right]$; $R = \{r_1, r_2, \ldots r_l,\}$ is the corresponding rules according to varied attribute values.

According to the above definition, the attribute value could be presented by $U = (S, A_t, V)$, and the corresponding connection between R could be presented as:

$$U_1 \wedge U_2 \wedge U_3 \wedge \ldots U_m >= R(r_1 \wedge r_2 \wedge r_3 \wedge \ldots r_n) \quad (m \geq 1, n \geq 1) \tag{1}$$

For example, the processing time a_5 of the reaction kettle s_4 is extended to $\left[\underline{v_2}, \overline{v_2}\right]$ (which is also presented by $U_1 = \left(s_4, a_5, v_2 = \left[\underline{v_2}, \overline{v_2}\right]\right)$, and then the corresponding rules are r_1 (adjust the preparing activity of the follow-up process) and r_2 (raise the process priority). In a word, the final expression form is $U_1 = \left(s_4, a_5, v_2 = \left[\underline{v_2}, \overline{v_2}\right]\right) >= R(r_1 \wedge r_2)$.

This method is easy

Rule-based scheduling process

From the extensive study of the firms, a fact should be admitted that the scheduling process heavily rely on the experience worker. The software can't replace the worker, especially for the multi-objective scheduling and varied production environment. So, in order to make the scheduling plan more effective, experienced rules should be paid more attention.

For this firm, three main objectives are considered during the scheduling process: delivery date, capacity utilization rate and kettle cleaning frequency. And "production order" could be presented as $J = (v, d)$, $v = (v_1, v_2, v_3, \ldots, v_N)^T$ is the total number of the consumer order v_i, the delivery date of the consumer order is $d = (d_1, d_2, d_3, \ldots, d_N)^T$.

The main work of the scheduling is to sequence the production order $J=(v,d)$, and make sure that all the above three objective can get a relatively satisfied value. This paper tries to make a new scheduling process that not only can be easily used in the real production, but also consider the rules extracted from the experienced workers. The steps of the process are as followed:

Step one: export the weekly production order $J_j=(v_j,d_j)$ from the ERP;

Step two: export the optimized data (processing time, machine capacity), and information based rules.

Step three: sequence the production order $J_j=(v_j,d_j)$ under each of the above three objectives, and note three different result as $Q_{1,j}\left(\frac{D_j-t}{t_j}\right)$(delivery date), $Q_{2,j}\left(\min\{C_j\}\right)$(capacity utilization rate) and $Q_{3,j}\left(\min\{T_{clean}\}\right)$(kettle cleaning frequency).

Step four: coordinate the weekly changed weight $w_m(d)$ of the three objectives according to dynamic information feedback and information-based rules weekly, and determine the final sequence of the production orders $Q_j=\sum_{m=1,2,3}\left(w_m(d)\cdot Q_{m,j}\right)$ [13];

Step five: adjust the scheduling plan daily according to the daily information feedback. Two main rules are used, rule one is to split the production order according to the daily production situation; rule two is to increase the utilization rate of some automation machines.

Rule 1: IF ($C_j>d_i\{d_i\in J_j\}$) THEN ($reduce(V(J_j))$ AND ($split(J_j\rightarrow J_{j,l}+J_{j,k})$ (2)

Rule 2: IF ($(T_{D-finish}-T_{D-end})\geq T_{J_{j+1},d+1}\pm t_0$) THEN ($J_{j+1,D+1}\rightarrow J_{j+1,D}$) (3)

Case study

To examine the method proposed in this paper, a test has been done in the firms, three Index are compared between the methods used before and after. Just depicted in the table1, the on-time delivery rate and utilization rate of automation machines has been improved, but the kettle cleaning frequency is increased slightly, the true reason is that rule1 increases both on-time delivery rate and the kettle cleaning frequency.

Table1 Index comparison

Index	before	after
On-time delivery rate	85.5%	90.5%
kettle cleaning frequency	11.2/week	12.1/week
utilization rate of automation machines	55%	65%

What' more, this method makes it more effective for the production planner to cope with daily work and dynamic production environment.

Summary

This paper tries to use the dynamic information and experience from workers, to improve the existing planning and scheduling process, a test states that the method proposed in this paper is helpful in the production, but several parts are still needed to study, such as optimize the algorithm and establish perfect expert knowledge base.

Keywords: information acquisition, sensors, production environment, tropical crop

Abstract. The information of tropical crop production environment includes the wind velocity and direction data, light intensity, air humidity, air temperatures, soil moisture, concentration of carbon dioxide, rainfall and so on. These data will be of great reference value to environmental control and scientific field management. As the characteristics of tropical crop growth and tropical climate conditions, information acquisition and tracking about the environment of crop growth are quite behind the time. This research is precisely centers on this core question to launch, carrying on analysis on the key technology of intelligent sensor and monitoring about tropical crop production environment. We build a system on a tiny210 chip using android operating system. Sensors that will be linked include air humidity & temperature sensor, illumination sensor, soil moisture sensor, wind-direction sensor and wind power sensor. This research focuses on field information dynamic acquisition and management. This study can offer references for in field environmental control and further research work.

Introduction

Now the studies of intelligent sensor and monitoring technology on tropical crop production environment include mainly the following several aspects: (1) data acquired portable terminal device[1-3], (2) the data collection and processing techniques include GPS, GIS, RS, RFID, sensor, wireless network, crop production model and infrared radiation spectroscopy technologies[4-9], etc, (3) information gathering and monitoring system[10-11]. The research emphatically analyzes the information of soil nutrients and moisture[12], intelligent management of water and fertilizer[13], information acquisition including field geographical information, moisture, soil, light, facility agriculture[14,15], etc.

Tropical crops require an appropriate growth environment for successful germination and establishment, because environment will directly affect the quantities and quality of the products. This study focuses on the field environment requirements for information technology in tropical crop production.The paper studies the key technique of intelligent sensor and monitoring, using sensor technology, monolithic integrated circuit, database and control technology, to explore an information collection system with the advantages of strong practicability, simple and convenient operation and low cost. The system can realize the dynamic monitor of the field environment, improve the field management and offer reference data for manipulation of field environment.

Key Technology

Overall Design. We will build a system of intelligent sensor and monitoring technology about tropical crop production environment, using sensor technology, monolithic integrated circuit, database and control technology. Android development environment and JAVA programming language are used in the software design of the controlling system. The hardware of the system includes TINY210 development board and sensors. Data acquired from the system includes wind

velocity and direction, light intensity, air humidity, air temperatures and soil moisture. The functions of the system include data collection, field production and management, and environmental control. The overall design of the system is as shown in Figure 1.

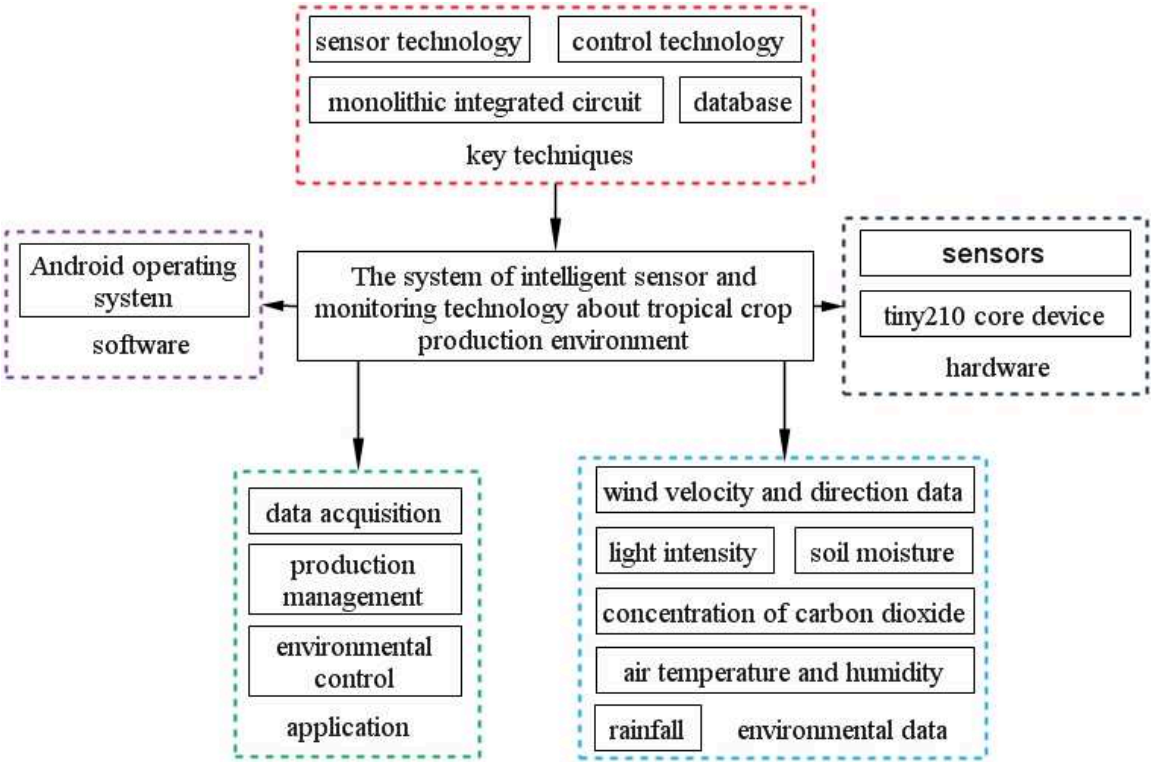

Fig.1 The overall design of the system

Software Design. Software Design uses eclipse programming tools, which is specialized for embedded systems based on android. The information acquisition system uses JAVA. The system design includes function require, datasheet design and interface code design. Background applications of the system operating interface is as shown in Figure 2.

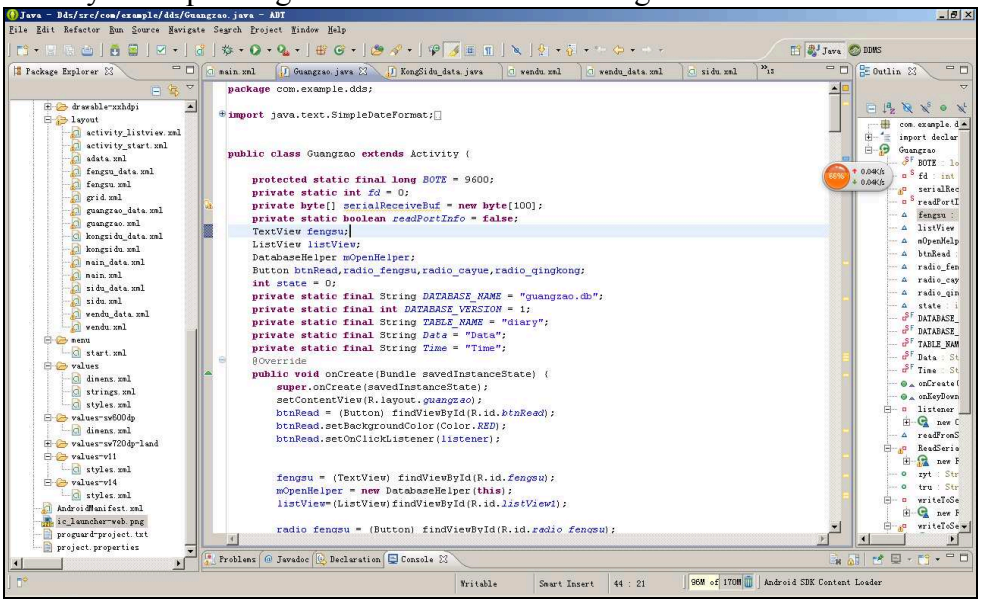

Fig.2 Background applications of the system operating interface

Main Interface of the System. Functions of the wind velocity and direction data, light intensity, air humidity, air temperatures, soil moisture, concentration of carbon dioxide, rainfall are designed in main interface in the system. The design of main interface of the system is as shown in Figure 3.

Fig.3 The design of main interface of the system

System Test. Precision test and dynamic application test have been done for the whole system experiment. Experiments showed that the system is feasible and practical. The test data of the system is as shown in Figure 4.

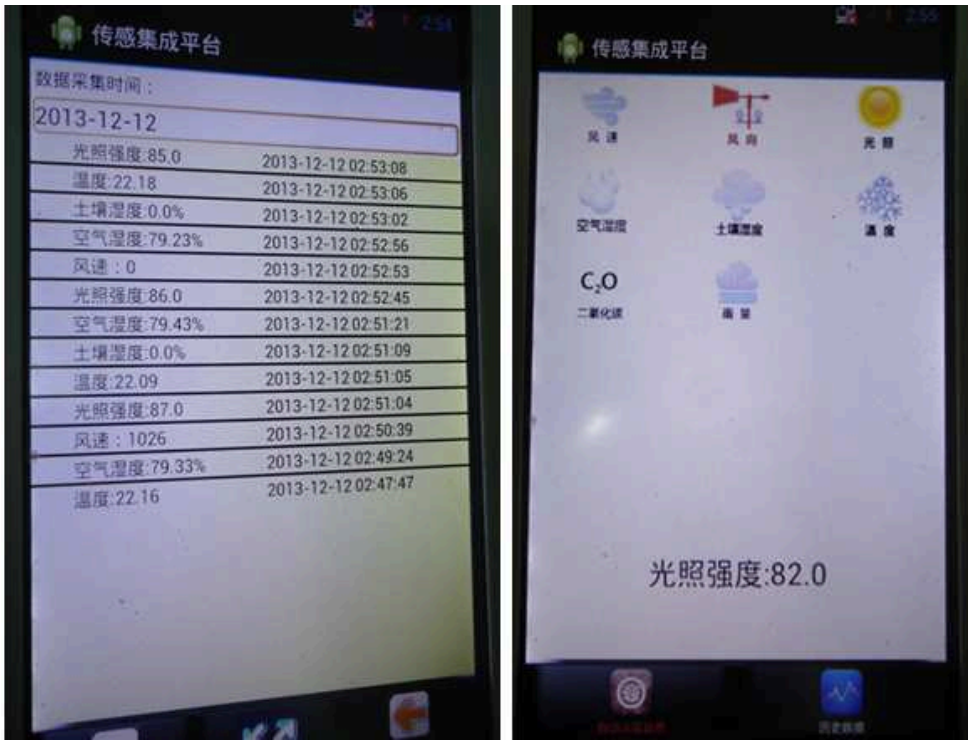

Fig.4 The test data of the system

Summary

With the development of information technology, it will realize intelligent and scientific management for tropical fields manegement. modern agricultural will be modernized and agricultural productivity will be raised.

Keywords: Explosion-Proof Diesel; exhaust purification; water-washing tank; numerical simulation; flow field

Abstract. In order to improve the cooling & purifying effect of exhaust, reducing the water-jetting phenomenon during working time, the waste-gas flow field simulation in water-washing tank of Explosion-Proof Diesel (*EPD*) was conducted through *ANSYS CFX*/*Fluent*. The results revealed the inner flow condition and outlet temperature of emissions in water-washing tank. It provided a reference for the future design and optimization of the water-washing tank of *EPD*.

Introduction

According to the Chinese Coal-mine industry safety standard, the waste gas of Explosion - Proof Diesel (*EPD*) must be cooled to the final exhaust temperature which is no higher than 70 ℃[1]. At present, from the perspective of safety and reliability, water-washing is the main cooling for the emissions of *EPD*. Taking the difference of output power and flame arrester grid layout into account, there are large variations in the shape and internal structure of the water-washing tanks. Through the washing process, the most carbon particles and NO_x from insufficient combustion will be coerced by water. For the obstruction of the stainless steel tank-walls, it is impossible to observe the gas-liquid flowing movement in tanks. It is also impossible to obtain the flow image even open an observation mouth on the tank-walls, because the observation mouth will soon be contaminated after the starting of diesel engine. Therefore, through the *ANSYS CFX/Fluent* module, the simulation of gas flowing in the exhaust water washing tank of *EPD* was conducted [2-9]. It is the only means to grasp the gas-liquid flowing condition inside the water-washing tank, and it will provide a reference for the future optimized design of water-washing tanks.

Simplifying and Setting of CFD Model for EPD

The water-washing tank consists of exhaust flame arrester, intake pipe, tank, partition board, diffuser, exhaust pipe and water-adding valve. All of them have great impact on the gas-liquid disturbing behavior during water-washing process. So it is necessary to take an interview to affect mechanism. In order to reduce the computing time, the un-important components, such as intake pipe, exhaust pipe, stiffener plates, flame arrester and float-ball valve chamber etc., were simplified away. Meanwhile, taking into account the symmetry of the model, as shown as in Figure 1, to further reduce the computational workload, the final analysis model is only 1/4 of the real water-washing tank. The model was meshed with free mesh method, and the model after meshing was shown in Figure 2.

In actually, the discharging velocity and flow capacity of *EPD* exhaust varied in a wide range. For the absence of exhaust data, this paper just provides a research method for the flow field interview of water-washing tank. So, in this simulation, the initial temperature of the gas-liquid two-phase flow equals 20 ℃, the surface tension coefficient equals 0.072 *N/m*, convection conduction heat transfer

coefficient equals 100 $W/m_2/K$. It is through the VOF method to track the interface and achieve the two-phase flow simulation field of water-washing tank. Taking one-way coupling method, the calculation time t equals 3 s, the time step $DELTA$ equals 0.01 s. Create a model with two non-buoyant fluid, air and water, and turn on Mesh Motion function, Thermal Conduction option set to Thermal Energy options. In the initial setup, it is required to set initial distribution and static pressure distribution with air and water VOF expressions. Meanwhile, set the inlet velocity Vinlet of 35.57 m/s, inlet temperature of 320 ℃, the exhaust pressure of 1 Atm.

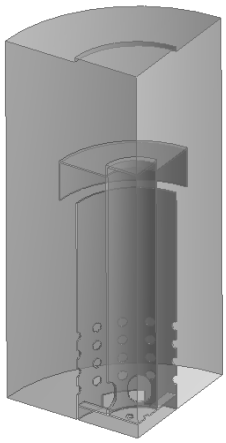

Fig.1 CFD model after simplification

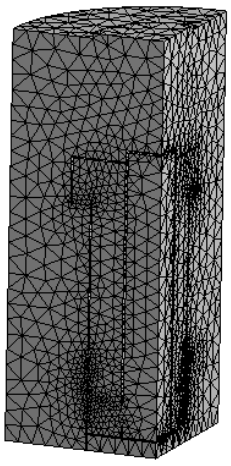

Fig.2 Mesh model of water-washing tank

Results of Simulation

Fig.3 is the serial photos of water volume fraction in water-washing tank at different time. From those photos, the changing processing of water volume fraction can be revealed, and the variation characteristics of water volume fraction can also be concluded. Before the 0.06 S, the interface between water and gas is clear. The 0.12 S was critical time, the water start to be coerced by exhaust and escaped finally. At 3.6 S, almost all of the water in water-washing tank had been taken away with the exhaust of EPDs.

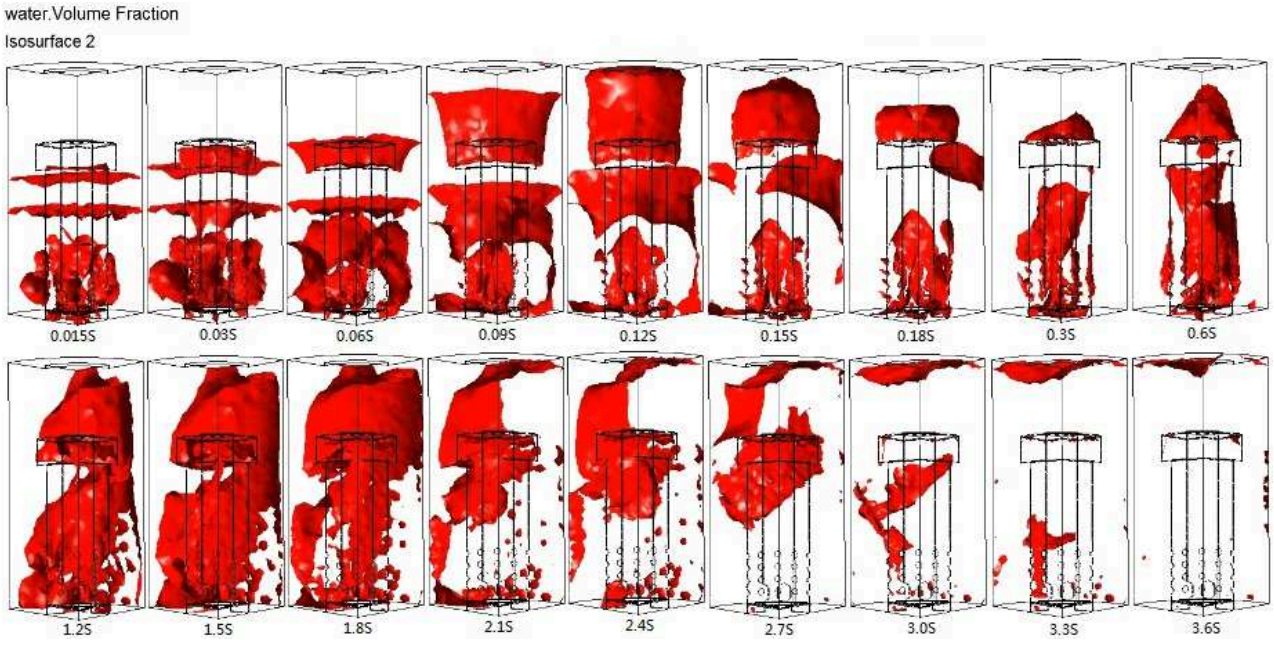

Fig.3 Water volume fraction photos inside of the water-washing tank at different time

Fig.4 is the serial photos of velocity flow field in water-washing tank at different time. From the simulation, the flow velocity vector & value of water-washing fluid inside of the water-washing tank

can be obtained. The following rules can be concluded: (a) the fluid velocity at the inlet and large holes of cavity is faster than other regions; (b) the fluid velocity gradually slowed down after flowing through the lumen to the outer chamber. The maximum fluid speed inside the water-washing tank is 80.37 *m/s*, around the large holes between the washing chamber and the inside of the outer chamber.

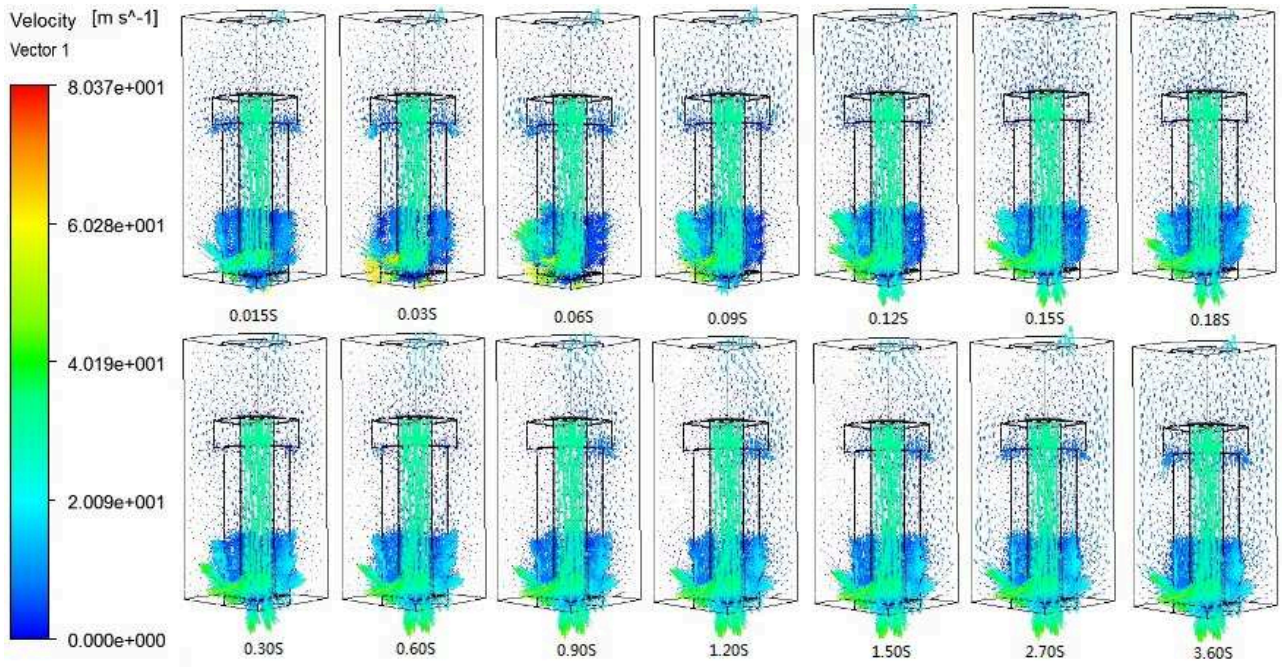

Fig.4 Velocity flow field photos inside of the water-washing tank at different time

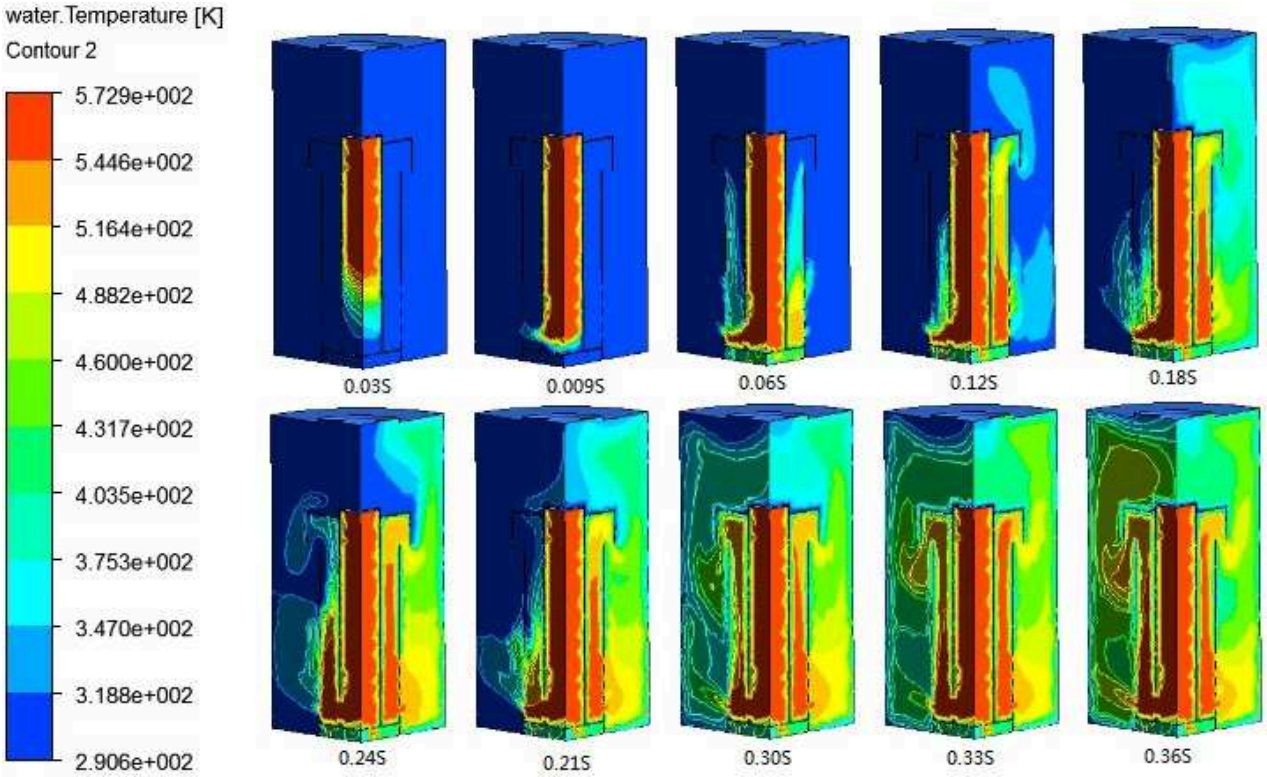

Fig.5 Distribution of the fluid temperature photos inside of the water-washing tank at different time

Fig.5 revealed the dynastic changing process of water-washing fluid temperature distribution inside of the water-washing tank from 1 *s* to 6 *s*. With the time increasing, the temperature of the water-washing fluid is gradually increasing. At the 2.1 *s*, the outlet temperature of water-washing tank equals 70 ℃(343 *K*); At the 6s, the outlet temperature of water-washing tank reaches 253 ℃ (526 *K*). This is because the simulation of water-washing process didn't take the water real-time

adding factor into accounting. So, at the 4S, it is almost all of the water had been taken away from the tank.

Conclusion

Through the simulation of the gas-liquid flow in water-washing tank of the *EPD*s, we could obtain the fluid velocity vector and temperature distribution inside of the water-washing tank. It provided a reliable method to study the complex flow condition inside of the water –washing tank of *EPD*s, and it also provided a reference for the future design and optimization of the water-washing tank of *EPD*. From the above results, the following conclusions can be gotten:.

1)The maximum speed of the fluid reached 80.37 *m/s* at the large hole between the chamber and the outer chamber inside water-washing tank.

2)With increasing time, fluid temperature in water-washing tank gradually increased. At 2.1 *s*, the outlet temperature of water-washing tank equaled 70 ℃; and it reached 253 ℃ at 6 *s*. This is because the simulation did not consider the real-time water replenishment of the water-washing tank. Therefore, in order to prevent the water-washing tank outlet temperature from increasing too high, we should always pay attention to the water replenishing during the operation of the equipment.

In the future, when considering the real-time replenishment water and exhaust flame arrester, we will do in-depth study the curve of temperature distribution, replenishment water rate, water level and exhaust temperature inside water-washing tank.

Keywords: jet, current field, wave, numerical modelling, flowing

Abstract. A variable density anisotropic turbulent buoyant jet model is applied for simulating the current field under waves. The numerical simulation results show the present model is efficient to describe the construction characteristic of current field. This model could be an efficient tool for sewage treatment by deep sea discharge.

Introduction

The sewage treatment by deep sea discharge has been become the major means in the nearshore district owing to the lower cost and environmental pollution. The sewage is mixed with environmental waters by jet means. So the jet characteristic of current field is key factor for the sewage deep sea discharge.

Jet's characteristic researched by the experiment and numerical simulation has been implemented for the sewage treatment by deep sea discharge. Many methods have been presented, such as dimensional analysis method [1], momentum integral method [2], differential equation method [3] and experimental method [4].

In this paper, a variable density anisotropic turbulent buoyant jet model is applied for simulating the current field under waves.

Anisotropic turbulent buoyant jet model

The jet's characteristics in flowing ambient fluid is studied by using the anisotropic turbulent buoyant jet model [5]. The governing equation is as follows:

Continuity equation:

$$\frac{\partial U_i}{\partial x_i}=0 \qquad (1)$$

Momentum equation:

$$\frac{\partial U_i}{\partial t}+U_j\frac{\partial U_i}{\partial x_j}=-\frac{1}{\rho_a}\frac{\partial P}{\partial x_i}+\nu\frac{\partial^2 U_i}{\partial x_j^2}-\frac{\partial \overline{u_i u_j}}{\partial x_j}+g_i\frac{\rho-\rho_a}{\rho_a} \qquad (2)$$

Concentration equation:

$$\frac{\partial C}{\partial t}+U_i\frac{\partial C}{\partial x_i}=\frac{\partial}{\partial x_i}(\lambda\frac{\partial C}{\partial x_i}-\overline{u_i c})+S_c \qquad (3)$$

An anisotropic algebraic stress model is applied to close the basic governing equation, as follows:

Turbulent kinetic energy equation:

$$\frac{\partial(\rho k)}{\partial t}+\frac{\partial}{\partial x_k}(\rho U_k k)=\frac{\partial}{\partial x_k}[c_k\rho\frac{k}{\varepsilon}\overline{u_k u_l}\frac{\partial k}{\partial x_l}+\mu\frac{\partial k}{\partial x_k})]+P_k+P_b-\rho\varepsilon \qquad (4)$$

Dissipation rate of turbulent kinetic energy equation:

$$\frac{\partial(\rho\varepsilon)}{\partial t}+\frac{\partial}{\partial x_k}(\rho U_k\varepsilon)=\frac{\partial}{\partial x_k}(c_\varepsilon\rho\frac{k}{\varepsilon}\overline{u_k u_l}\frac{\partial\varepsilon}{\partial x_l})+c_{\varepsilon1}\frac{\varepsilon}{k}P_k+c_{\varepsilon3}\frac{\varepsilon}{k}P_b-c_{\varepsilon2}\rho\frac{\varepsilon^2}{k} \quad (5)$$

Algebraic stress equation:

$$-\overline{u_i u_j}=\frac{k}{c_1\varepsilon}\frac{1}{\rho}\{(c_2-1)P_{ij}+(c_3-1)P_{ij,b}-\frac{2}{3}\delta_{ij}[c_2P_k+c_3P_b+\rho(c_1-1)\varepsilon]\} \quad (6)$$

Turbulent concentration propagation equation:

$$-\overline{u_i c}=\frac{k}{c_{T1}\varepsilon}\frac{1}{\rho}[(-P_{i,T}+\rho(1-c_{T3})\beta g_i\overline{cc}-\rho c_{T2}\overline{u_m c}\frac{\partial U_i}{\partial x_m} \quad (7)$$

Pulsating concentration squared equation:

$$\overline{cc}=-\frac{1}{c_{\theta1}}\frac{k}{\varepsilon}\overline{u_k c}\frac{\partial C}{\partial x_k} \quad (8)$$

The turbulent equations (2)-(9) is closed as the initial and boundary conditions are determined. In this paper, the variable density turbulent buoyant jet is considered by introducing the density state equation.

$$\rho=\frac{(C-C_a)\rho_0-(C-C_0)\rho_a}{C_0-C_a} \quad (9)$$

To study the influence of jet water's density, this paper introduces a buoyancy coefficient. It expresses the changing rate of water's density as the concentration of pollutant changes.

$$\beta=\frac{1}{\rho_a}\frac{\partial\rho}{\partial C}=\frac{1}{\rho_a}\frac{\rho_0-\rho_a}{C_0-C_a} \quad (10)$$

Boundary conditions:

Inlet section: $u=u_{in}$, $v_{in}=0$, $w=w_{in}=0$, $k=k_{in}=0.058(u_{in}^2+v_{in}^2+w_{in}^2)$, $\varepsilon=\varepsilon_{in}=k_{in}^{3/2}/(0.4h)$, $c=c_{in}$

Outlet section: $w=0$, $\frac{\partial}{\partial x}[u,k,\varepsilon,c]=0$

Free surface: rigid-lid hypothesis is used. $w=0,\frac{\partial}{\partial z}[u,k,\varepsilon,c]=0$

Side: $\frac{\partial}{\partial y}[u,v,w,k,\varepsilon,c]=0$

Wall [6]: $u=v=w=k=\varepsilon=0$, $\frac{\partial c}{\partial y}=0$, $\frac{\partial c}{\partial z}=0$

Jet inlet section: $u=u_0=w_j\cos\theta$, $v=v_0=0$, $w=w_0=w_j\sin\theta$, $c=c_0$, $k=k_0=0.058w_j^2$, $\varepsilon=\varepsilon_0=k_0^{3/2}/(0.4D)$, where, w_j is the initial velocity of jet; θ is the jet angle, D is the diameter of jet spout.

Case study

Set of the model parameters and mesh. In this paper, a case study is used to describe the current field characteristic. In this case, the model parameters are set as the values which are shown in the Table 1. In this table, T is the period of wave; L is the length of wave; H is the height of wave; U_w is the characteristic velocity of wave; R_j is the jet ratio. The computational region is divided into many pieces as shown in the Figure 1. The size of mesh is from 0.2cm to 2cm.

Table 1 Model parameters set

D（cm）	w_j（cm/s）	h（cm）	T（s）	L（cm）	H（cm）	U_w（cm/s）	R_j
2	50	50	1.18	200	4.5	7.60	6.58

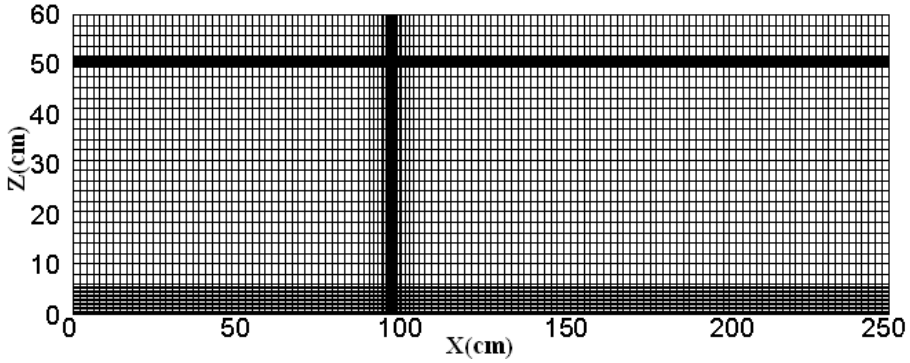

Fig.1 Diagram of computational mesh

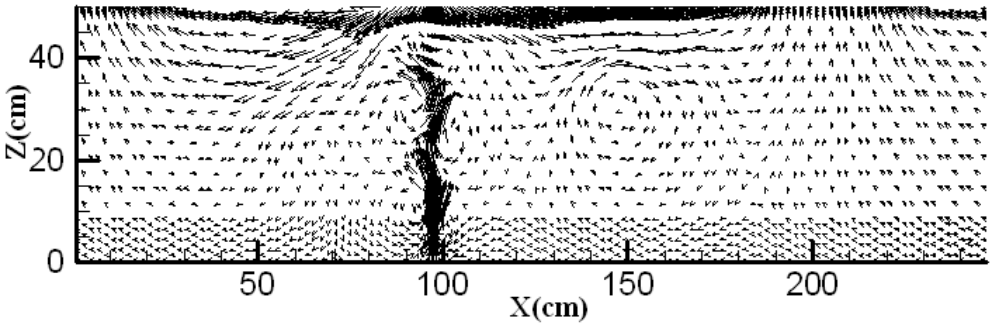
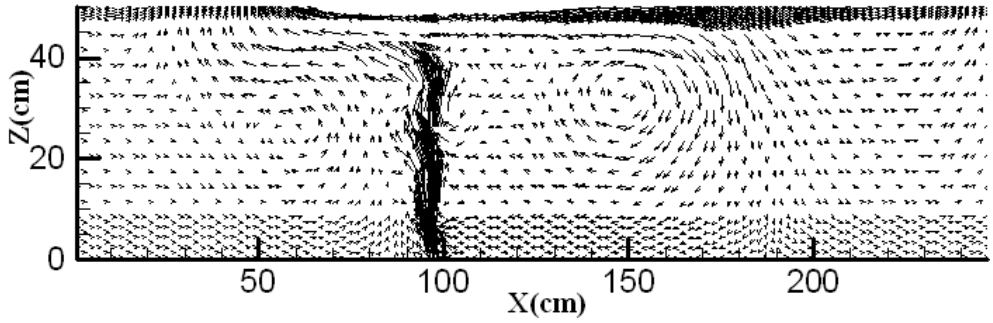
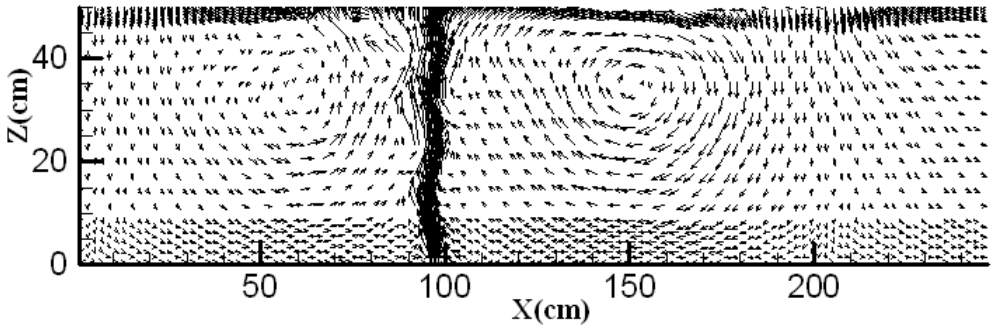
Results of numerical modelling. Input the model parameters into the jet model, the results are obtained. The instant current field is shown in the Figure 2.



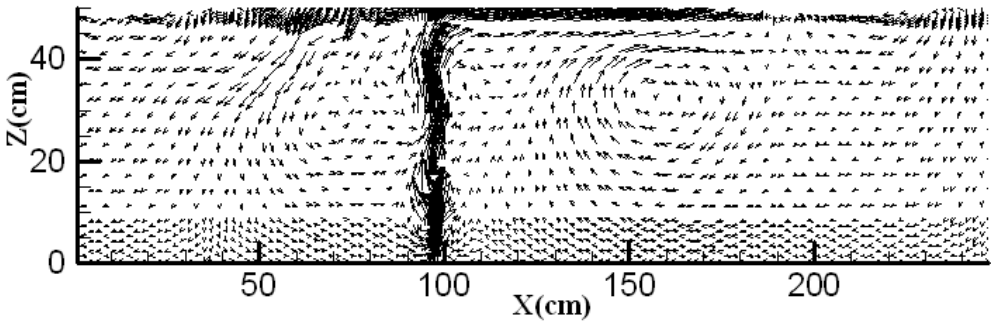
（a）t=11.80s



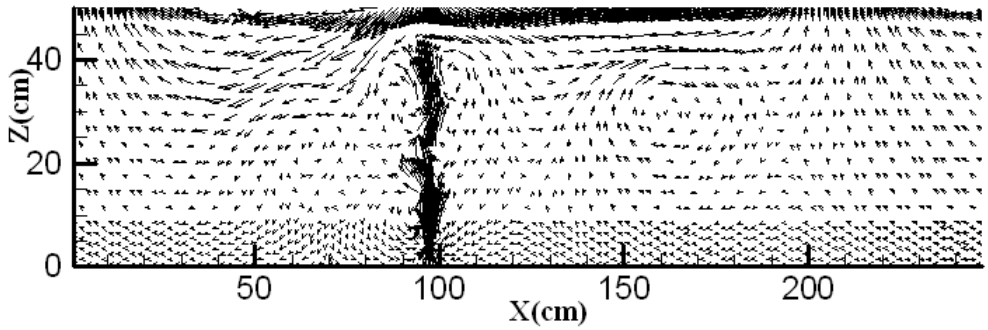
（b）t=12.09s



（c）t=12.39s



（d）*t*=12.68s



（e）*t*=12.98s

Fig.2 Instant current field

Fig. 2 shows the instant current field of simulation results. The numerical simulation results show the jet construction of current field under waves. The whole current field is very complicated. Small vertexes exist near the jet nozzle and the big vertexes occur far from the jet nozzle.

Conclusions

In this paper, a variable density anisotropic turbulent buoyant jet model is used for modeling the jet under waves. The numerical simulation results show the present model is efficient to describe the construction characteristic of current field. This model could be an efficient tool for sewage treatment by deep sea discharge.

Feedforward Improved PID algorithm to control the smart car

Yinghui Xie[1, a], Xiaoqiu Liu [1, a]

[1] School of Information Science & Engineering, Hunan International Economics University,Changsha, China

[a] e-mail:matlab_wjf@126.com

Keywords: Feedforward, improved PID algorithm, fuzzy, smart car.

Abstract. In the self-designed smart car, to control the speed and direction is the control core of the intelligent vehicle system . Due to hardware limitations, there is a delay in the smart car speed and direction control, which is adversely affected for the control of the smart car . For the above problems, the intelligent vehicle control will be applied by the feedforward and feedback control methods, the disturbance which is caused by the deviation will be treated in advance, Digital PID algorithm is improved , the incomplete differential and differential current algorithm is introduced to the PID algorithm to improve the dynamic performance of the system. Aftet this new algorithm is adopted, the dynamic performance of the intelligent vehicle system has been greatly improved.

INTRODUCTION

Smart car system is a time-varying and nonlinear systems using conventional PID feedback control algorithm for a single system will overshoot varying degrees of oscillation, can not get the desired control effect. This article will feedforward control is introduced to control the smart car system, effectively improve the real-time system, improve the response speed of the system [1]; and according to the characteristics of intelligent vehicle systems, digital PID algorithm has been improved by introducing the differential forward and incomplete differential links, improve the dynamic characteristics of the system; same time, the use of fuzzy control has not sensitive to parameter variations and robustness characteristics [2], this paper, fuzzy algorithm and PID algorithm combined effectively improve the smart car's adaptability and robustness, improved control system performance.

IMPROVED PID ALGORITHM

Smart car control is done by Freescale S12 chip, so the smart car control to computer control methods. In this paper, the particularity of intelligent vehicle control, the traditional digital PID algorithm made some improvements, so you can better meet the needs of intelligent vehicle control. Improved PID algorithm.

A. Incomplete differential PID

The direction and speed of the differential control aspects of the introduction of the smart car, obviously improves the dynamic performance of the system, but the error is particularly sensitive to disturbance mutations, stability of the system has some adverse effects. To overcome these shortcomings, the order inertia are incomplete differential PID algorithm are added in a PID algorithm[3].

The first-order inertia link directly applied to the differential link, the system transfer function can be obtained as follows:

$$U(s)=(K_p+\frac{K_I}{s}+\frac{K_D\cdot s}{1+T_f\cdot s})=U_p(s)+U_I(s)+U_D(s) \quad (1)$$

The term is derived differential equation (1) and finishing, get the following equation:

$$u_D(k)=K_D(1-\alpha)[e(k)-e(k-1)]+\alpha\cdot u_D(k-1) \quad (2)$$

Where, by the time constant of the system is a constant and a time constant of order inertia decision. To facilitate programming, can be written as (2) type:

$$\begin{aligned} u_D(k)&=K_D(1-\alpha)e(k)+\alpha u_D(k-1)-K_D(1-\alpha)e(k-1)\\ &=K_D(1-\alpha)e(k)+H(k-1) \end{aligned} \quad (3)$$

Where, $H(k-1)=\alpha\Delta u_d(k-1)-K_d(1-\alpha)e(k-1)$.

Analysis of formula (3) shows that after the introduction of incomplete differential, differential output in the first sampling period is reduced, then they follow a certain percentage of attenuation [3] [4]. Experiments show incomplete differential effectively overcome the bias of intelligent vehicle speed control interference to the adverse effects of having better control effect. Figure 1 is incomplete differential PID algorithm program flow.

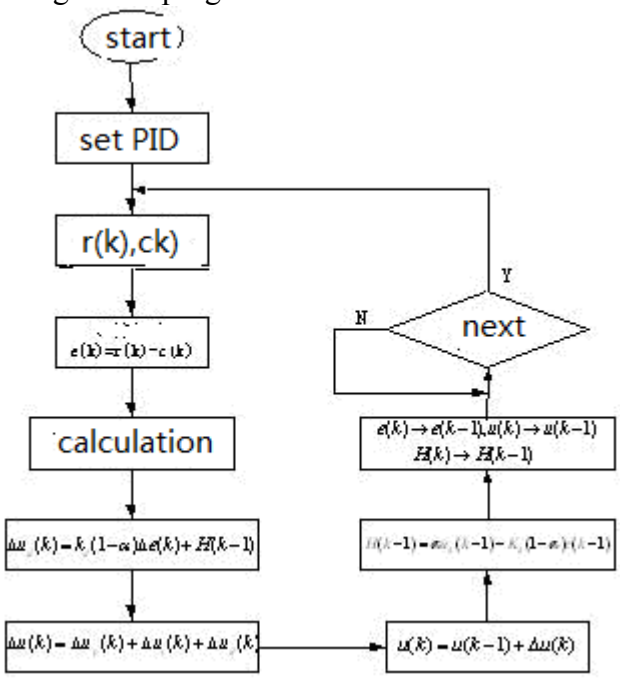

Figure 1. Incomplete differential PID algorithm program flowchart

B. Differential forward PID

As the Smart car driving on the track, turning often encounter the situation, so intelligent vehicle speed setting and direction setting changes frequently occur, resulting in an oscillating system. To solve the adverse effects of frequent changes to the system settings to bring this article on the smart vehicle speed and direction of advance of differential PID control algorithm is introduced, which is characterized by only the output of the differential amount, i.e., only the speed and the measured value differentiating the steering deflection amount, speed and direction without setting the differential value. Thus, when the setpoint changes, output does not change, but the relative change in the amount charged is more relaxed, which nicely avoids oscillation frequent changes to the system settings caused, apparently improves the dynamic performance of the system.

Differential first incremental control formula below.

$$\Delta u(k)=K_p[e(k)-e(k-1)]+K_i\cdot e(k)-K_d[c(k)-2c(k-1)+c(k-2)] \\ -K_d[c(k)-c(k-1)] \quad (4)$$

FEEDFORWARD CONTROL APPLICATIONS

Because smart car track width is limited, so after a sharp turn when, if the speed and direction control is not timely, intelligent vehicles could runway. Since the feedforward control is the open loop control, feedforward control response speed quickly. The feedforward control is introduced into the smart car control, to improve the response speed servo and servo motors, improving dynamic performance of intelligent vehicle systems.

*C. **Intelligent vehicle control system architecture***

Smart car control is mainly reflected in two aspects: one is to control the direction, that is, control of the steering gear; the other is for speed control, that is, the servo motor control. Servos relatively simple mathematical model has good linearity characteristics, using only feedforward control; intelligent vehicle speed control is relatively complex, the velocity model can not be

accurately established, feedforward - Improved PID control algorithm. Smart car control system architecture is shown in Figure 2.

This figure is a mathematical model of the servo motor and servo. As can be seen from the drawing, the intelligent control of the vehicle direction and speed are controlled independently of each other, and they are determined by the route deviation. Correspondence between the steering angle and route deviation between the mathematical model is based on the resulting steering, speed control loop, both feedback loop also includes the amount of feed forward control, servo motor is based on feedforward compensation then calculated by the incremental PID algorithm.

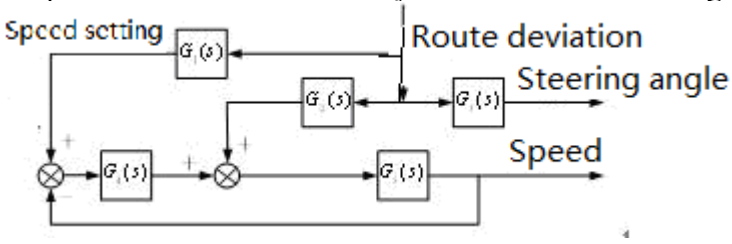

Figure 2. Smart car control system architecture

D. *Application In the directional control*

Control of the direction of the smart car has two requirements: on the straights, the direction remains stable; in the corner, you need to change direction quickly and accurately. The only way to ensure that the smart car speed, stable operation on the runway. In order to improve the robustness of directional control, the paper also carried a route deviation fuzzy processing. Figure 3 is a block diagram of fuzzy intelligent vehicle direction feedforward control, block diagrams $G_Z(s)$ and $G_W(s)$ are two cases before the straights and corners under feedforward control functions.

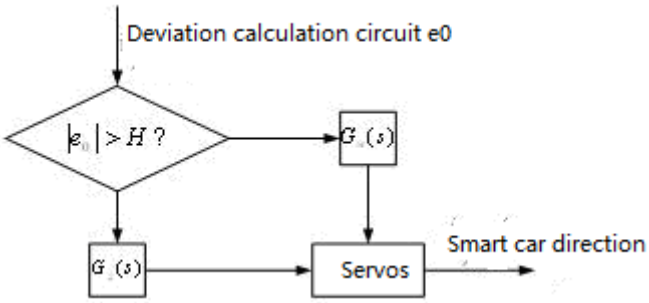

Figure 3. Intelligent vehicle directional control system structure

E. *Application In the speed control*

In order to make the smart car on the straight run at a faster speed, in turn, prevents the smart car skidded off the runway, you must reduce the speed of the smart car, which requires intelligent vehicle speed control system has good acceleration and deceleration performance. When the Smart car through continuous turning track, the frequent changes in the route deviation will result in frequent changes in speed setting, which may cause oscillation speed control systems, and differential interference links for error is very sensitive mutations, likely to cause system instability. In order to solve the above problems, this paper digital PID algorithm has been improved, will not be fully differential and differential first introduced to the PID algorithm, which greatly improves the dynamic performance of the speed control system.

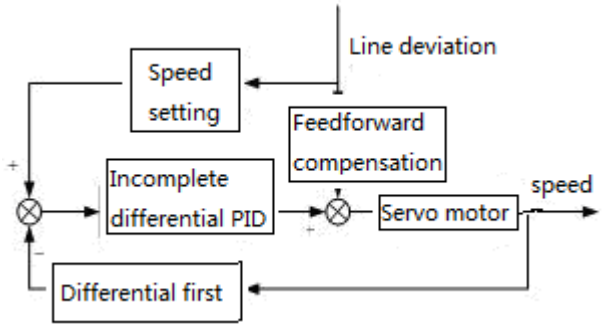

Figure 4. Intelligent Vehicle speed control system structure

Figure 4 is an intelligent vehicle speed control system structure. Due to road conditions and the smart car track attitude will often change, so the speed control system model is also uncertain, in order to improve the adaptability of the system, speed control system, this paper uses a fuzzy PID algorithm. The speed and the actual speed of the fuzzy set of files [5] [6], obtained under different conditions relative to the optimal PID parameters through commissioning, to ensure that the speed control system in different circumstances have good control effect.

CONCLUSIONS AND OUTLOOK

The proposed feedforward - Improved PID algorithm is an effective way to control the smart car, the algorithm makes intelligent vehicle system[7-11] not only has a good dynamic performance and reaction speed, and improve the adaptability and robustness of the system, make the smart car can run on different runways at a faster rate. Experimental results show that: the proposed control algorithm effectively improve the smart car's performance, running on the same runway, using a new algorithm for intelligent vehicle than traditional PID feedback control algorithm for intelligent vehicle speed has increased, running a reduce the average lap time of 3.2 seconds, and the proposed algorithm makes intelligent vehicle running stability improvements, improved adaptability smart car on the runway. This method has a good prospect.

Keywords: Ahmed model; External flow filed; Turbulence model; RANS

Abstract. For vehicle external aerodynamic computation, the selection of the turbulence model is very important. In current research, ten RANS turbulence models were introduced to compute the time-averaged flow field around the Ahmed model with 25° backlight angle. In order to evaluate the feasibility of the turbulence model, the results were compared with the related published experimental data. The results showed that the two equations RANS turbulence models were more favorable to compute the vehicle external flow field, but parts of the two equations turbulence model just could predict the aerodynamic drag coefficient or lift coefficient effectively. However, the results further revealed that the realizable k-ε could obtain the more accurate drag coefficient and lift coefficient simultaneously, and simulate the complex separation flow in the wake.

Introduction

The external aerodynamics is concerned with many relevant aspects of a ground vehicle such as handling stability, comfort and fuel consumption [1]. Flow field around road vehicles is highly three-dimensional, unsteady, separated and turbulent. The main contributions to aerodynamic drag for a bluff body type vehicle are the flow separation in the rear, causing pressure recovery losses and vorticity in the wake. With the rapid development of computer power, the computational fluid dynamic (CFD) was introduced as a new technological solution for the design and testing. It is unquestioned that the numerical simulations could perform in-depth analysis to the complex phenomena without resorting to expensive prototypes and difficult experimental measurements. This trend, to bring CFD to bear on vehicle aerodynamics design issue, is appropriate and timely in view of the increasing competitive and regulative pressure being faced by the automotive industry [2]. For the application of CFD in vehicle aerodynamic simulation and its significant, Hucho [1] had performed a comprehensive review. Since the first researchers [3, 4, 5] applied CFD to vehicle external aerodynamic prediction, applications of CFD for airflow predictions around the vehicle have become widespread. However, since the turbulence models in CFD used approximations, the simulation results may contain uncertainties. Therefore, it is very important to evaluate the generality and robustness of the turbulence model for predicting airflow around a vehicle.

In order to investigate the performance of turbulence models for complex geometry cases, a simplified car model, known as the Ahmed body [6] was often employed as a benchmark in vehicle aerodynamic. The Ahmed body is a generic car type bluff body shape which is enough simple for accurate flow simulation but retains some important practical relevant features of automobile bodies [7], as shown in figure 1. More detailed measurements using LDA for the backlight angle 25° have been performed by Lienhart and Becker [8]. With the availability of published experimental data and the advantage of simple surface geometry, the Ahmed body became a popular test case to validate the computational accuracy, meshing strategy, turbulence modeling and so on.

In the literature, a certain number of researches are now available for the angle 25°of the backlight angle using different turbulence modeling approaches. At first, the RANS or unsteady RANS (URANS) approaches were employed to compute the external flow field and the turbulence models employed varied from standard k-ε model, k-ω model, Explicit Algebraic Reynolds Stress

Model to Reynolds Stress Model. However, The flow computed for the slant angle 25° does not match the experimental results, and Krajnović[9] argued that the possible reasons of the failures may be that the shear due to the partial detachment of the flow on the upper part of the slant related to a Kelvin-Helmholtz instability, which significantly increase the momentum transfer across the mean streamlines and enhance the three-dimensionality as well as the unsteadiness of the flow.

Many RANS turbulence model had been employed to investigate the flow field around the Ahmed model, and the performance of the different turbulence model were also compared partly. It can be concluded that, for the simulation of vehicle external flow filed, each turbulence model has its own advantages. However, there are no systematic analyses and comparisons for the different turbulence model in the vehicle aerodynamic simulation. Therefore, in current research, in order to investigate the performance of the different turbulence model in the vehicle aerodynamic simulation comprehensively, the different RANS models were employed to compute the exterior flow filed around the Ahmed model.

Geometry and computational parameters

The Ahmed model is shown in Fig. 1. Here, only the 25° backlight angle is investigated. The length of the model is L =1044 mm, the width is W =389 mm, the height is H =288 mm. The ground clearance is G =50 mm, and the diameter of the four feet, which are used to fix the model to the floor of the wind tunnel, is Φ = 30 mm. The reference axis (X, Y, Z) is linked to the model. The origin of these axes is related to the point O located on the floor of the wind tunnel at the base of the model and in the symmetry plane of the model.

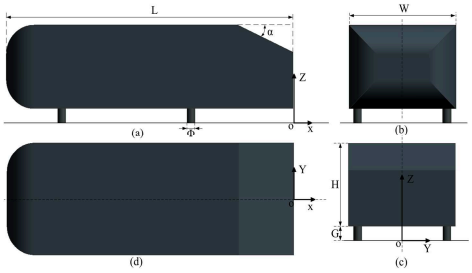

Fig.1 Side, rear, front and top view of the Ahmed body and the coordinate system

The upstream velocity is V_0=40 m/s. The computational domain starts 2L in front the model and extends to 5L behind the model. The cross-section of the computational domain is 1.87 m and its height is 1.4 m, which gives a blockage ratio of 4.3%, is identical to the open test section of the wind tunnel used in the experiments [8]. The boundary conditions are no slip walls for the Ahmed body geometry and the floor of the computational domain, while the roof and the side walls of the computational domain are treated as slip walls. At the inlet, the uniform velocity V_0 is imposed while at the outlet, the pressure is imposed.

Numerical method

In current research, Spalart-Allmaras model, standard k-ε, RNG k-ε model, realizable k-ε, standard k-ω, Shear-Stress Transport (SST) k-ω, the k-kl-ω transition, Explicit Algebraic Reynolds Stress, v2f model, Reynolds stress model were employed to compute the flow field around the Ahmed body, and the performance of the turbulence models was evaluated and compared.

All these turbulence model equations mentioned above can be written in a general form as:

$$\rho\frac{\partial\bar{\phi}}{\partial t}+\rho\frac{\partial\overline{u_j}\bar{\phi}}{\partial x_j}-\frac{\partial}{\partial x_j}\left[\Gamma_{\phi,eff}\frac{\partial\bar{\phi}}{\partial x_j}\right]=S_\phi \tag{1}$$

Where ϕ is variables, $\Gamma_{\phi,\,eff}$ is the effective diffusion coefficient, and S_ϕ is the source term. Due to the space limit of the paper, a more detailed description of these models is not possible. Since many of the models are available in some commercial software, one could also refer to the user manual.

This study used commercial CFD software, FLUENT to conduct all the numerical investigations. The RANS models used the second order upwind scheme for all the variables except pressure. The discretization of pressure is based on a staggered scheme, PRESTO! The SIMPLE algorithm was adopted to couple the pressure and momentum equations. If the sum of absolute normalized residuals for all the cells in flow domain became less than 10^{-3} for all variables, the solution was considered converged. Grid dependence of each case was checked using two different grids to ensure that grid resolution would not have a notable impact on the results.

Results and Discussion

According to the drag force coefficient showed in table 1, most of the turbulence models were over-predicted, and the Realizable *k-ε*, SST *k-ω*, RSM and Transition SST whose error were within 5% may be considered more accurate, especially for the SST *k-ω*, the error was -1.75%. However, for the lift force coefficient, all the turbulence models were under-predicted relative to the experimental data, and the results revealed that Realizable *k-ε*, Standard *k-ε* and *k-kl-ω* whose errors were within 5% may be considered more accurate, especially for the Realizable *k-ε* the error was about -1.75%. Based on the comprehensive analysis of the drag coefficient and lift coefficient, it could be concluded that although parts of the turbulence models could predicted the drag coefficient, the error of the lift coefficient was unreasonable, such as SST *k-ω*. In other words, these turbulence models cannot predict the aerodynamic force fully. However, not only for the drag coefficient, but also for the lift coefficient, the Realizable *k-ε* could obtain more accurate results. Therefore, the Realizable *k-ε* was better for the prediction of aerodynamic force.

Table 1 Drag and Lift force coefficient

	Cd			Cl		
Turbulence model	CFD	Experiment	Error (%)	CFD	Experiment	Error (%)
Realizable *k-ε*	0.294	0.285	3.16%	0.393	0.400	-1.75%
RNG *k-ε*	0.308		8.07%	0.377		-5.750%
Standard *k-ε*	0.479		68.07%	0.388		-3%
SST *k-ω*	0.280		-1.75%	0.263		-34.25%
Standard *k-ω*	0.851		198.60%	0.365		-8.75%
RSM	0.275		-3.51%	0.255		-36.25%
S-A	0.348		22.11%	0.379		-5.25%
k-kl-ω	0.364		27.72%	0.385		-3.75%
Transition SST	0.291		2.11%	0.355		-11.25%
v2f	0.327		14.74%	0.242		-39.5%

In order to evaluate the predication ability of the turbulence model for the aerodynamic characteristic further, the mean velocity profiles of the tail were extracted to compare with the experimental data (see Fig.2, the square legend is the experimental data). The experimental data is provided by the Prof. Becker [8] at the Universitaet Erlangen-Nuernberg in Germany. The results revealed that the airflow attached on the surface, and did not separate except for the standard k-ω at X/L=0.80. Perhaps this was the reason why the error of the drag coefficient predicted by the standard k-ω reached to 198.6%. At X/L=0.89, the airflow began to separate, and the separation became stronger and stronger as the distance increase. For the wake, especially for the center of the wake, the results obtained by the Realizable *k-ε* were closer to the experimental data. Therefore, the results of the mean velocity profile of the wake could further explain why the Realizable *k-ε* could predict the external flow field fully and accurately.

Conclusion

In current research, ten RANS turbulence models were introduced to compute the time-averaged external flow field of the Ahmed model with 25° backlight angle, and the accuracy of the turbulence model in the vehicle external flow field were evaluated by comparing the result with the related published experimental data.

Results indicate that the scale of the wake vortex obtained by numerical is smaller than that of the experimental result. The two equations RANS models were more favorable for the computation of vehicle external flow field. The realizable k-ε could obtain more accurate drag coefficient and lift coefficient simultaneously, and simulate the complex separation flow in the wake.

Compared with the Ahmed model in current research, the external aerodynamics of a ground vehicle is more complex. Therefore, the future investigation should include the vehicle wheel and the accessories of the vehicle and so on. And the vehicle aerodynamic simulation also should be computed by coupling the flow field of the internal with external aerodynamics. Moreover, flow field at the rear end of road vehicles is highly unsteady, so DES (detached eddy simulation) or LES (large-eddy simulations) model should be taken to investigate the transient characteristics of the wake vortex in the future.

Keywords: Near Space Airship; Performing Environment, The Envelope Material, Ground Simulation Test, Weathering Performance

Abstract. Performing characteristics on envelope composite of near space airship (NSA) are quite different from that of the low altitude airship essentially. The NSA envelope material should meet excellent applicative characteristics including light weight, high strength, anti-aging, anti-ultraviolet radiation, gas-tightness, weather resistance. Ground simulation test is critical for the envelope design and development process of NSA, and the environmental features of near space is analyzed for NSA, then corresponding ground simulation test methods are proposed to involve mechanical strength of the ground test methods among the changing weather temperature and over pressure changes, materials weather resistance and air tightness test. Finally the coupling relationship between various mechanical test and environmental test methods is also investigated.

Introduction

With the development of high strength envelope material and cycle solar energy technology, the near space airship attract more and more interest of researchers [1]. As near space airship plays critical roles in various areas involving long-term floating in space, high detection, fixed floating, operational effectiveness evaluation, missile defense, ECM (electronic countermeasures) and others [2].However, it is a quite long way to realize engineering application of high altitude long-term floating airship in near space [3]. And with the severe influence of wind, thermo, UV (ultraviolet) and other stratospheric environmental factors, the mechanics and reliability of flexible envelope composite material degenerate gradually. Consequently, Micro cracks or micro holes go expansion and the envelope material become failure [4].

Single mechanism or multiple coupling mechanisms influence of near space environmental factors further accelerated the performance degradation. Consequently the mechanics of material, physical and chemical properties decreased badly [5]. The performance of airship envelope material has two aspects together including the mechanical properties of both fabric yarn bundles and composite laminated or coated properties. Currently the related available studies mainly focus on macro-mechanical properties and material fatigue life of airship envelope under single environment affecting factors [6], and usually combined with the flight test or ground simulation environment measurement to test the mechanical characteristics of the airship envelope under the influence of complex space environment [7]. Because the current commercialization envelope material on the domestic market mainly relied on foreign imports. So this results in the lack of intellectual property rights of self- development performing materials of near space airship, and the scientific test standard and testing methods of NSA envelope have not formed.

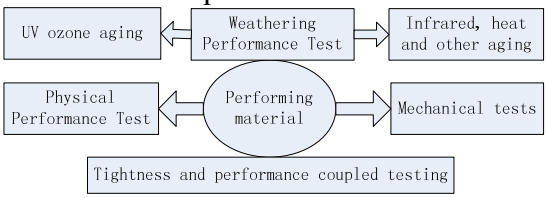

Fig.1. A integrated schematic diagram for ground simulation test methods of performing material

Based on the previous studies, the ground simulation test methods are analyzed under multiply near space environment factors shown in Fig. 1. The physical properties and mechanical strength simulation tests of long time performing envelope are investigated and summarized including temperature changing and over pressure changing in near space environment. Then coupling relationship is further analyzed between the various test methods, and major factors are also noted for selecting long-endurance performing envelope composite.

Test methods for the physical properties of the envelope material

Spacecraft can work for a long time and it requires envelope material has a high efficiency of weight. That is to say that weight of envelope material will be small and we usually use specific gravity (weight) to measure its size. So the per surface density should be below 135g/m2 and the envelope material requires uniform texture. Thickness of material are tested by GB/T 3916-1997 standard shown in Fig. 2. Thickness of the envelope material is generally less than 0.35mm.

Fig.2. Envelope material laminated fabric thickness tester

In recent years, more and more researchers are also concerned about the flexible airship envelope material components, as well as skin material components in space under the influence of environmental factors in the fiber bearing layer, blocking helium layer, layer aging resistance micromechanics characterization, and forecast stratosphere envelope material in real-fatigue life. Airship envelope material is a multilayer film laminate; using high strength polyethylene filament a aliphatic Veteran fiber reinforced TPU film laminated synthetic material in Fig 3 (a). The film thickness is 0.16mm and the inner layer is formed by 10 feature films adhesive bonding together, as shown in Fig 3 (b). Fibers are the plain weave braid and physical geometric parameters are shown in Table 1, which are measured by standard test equipment.

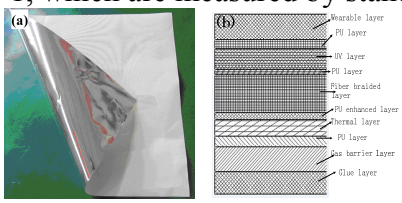

Fig.3. Envelope specimens

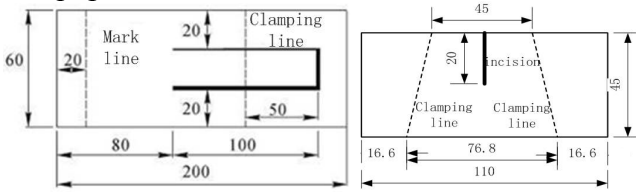

Fig.4. Parameters of test specimen (mm)

Table 1 The mechanical parameters of specimens

Thickness	Fiber bundle density	Yarn density	The areal density of the material
0.16mm	10*10 root/cm	220tex	130g/m^2

Ground simulation methods for the mechanical strength of the envelope material

Mechanical strength contains strength index and elasticity parameters. A method to simulate the mechanical properties is uniaxial and biaxial tensile test. The former can be used to determine the tensile strength of unidirectional performance, elongation at break and tear strength. Tensile test specimens generally are rectangular sample which can be divided into radial test specimen and the weft pieces by the direction of the filaments. Size detection plane are often used in the industry standard test material shown in Fig. 4. According to the results of a flexible material woven fiber Vectran, composite test data based on found trapezoidal method test data error is smaller, mainly because with using the trapezoidal method during the test, the sample is less disturbing factors affecting the tensile mechanical strength testing.

The more important factor is the shear strength. Adhesive layer strength in different space environment between the coating layers plays a decisive role. Thus the ground simulation tests need to consider the mechanical strength of the adhesive layer under different conditions of temperature and radiation. Here mainly test method for linear expansion characteristics of the test method according to standard GB1036-89. The quartz tube tester can be chosen and its test accuracy is 0.002mm. In accordance with the adhesive properties, then:

$$\overline{\alpha} = \frac{L_2 - L_1}{l(t_2 - t_1)} \tag{1}$$

Where t_1 represents the temperature of the material at low temperature, ℃; t_2 represents the temperature of the material at high temperature, ℃; l_1 represents a length of the material at low temperatures, mm; l_1 represents a length of the material at high temperature, mm; l of raw material length, mm. If the envelope deformation is too large, the adhesive layer is likely to produce deformation or separation degumming, resulting in the destruction of the whole structure of the envelope material. Mechanical shear strength can be measured by the tensile test method and we also need to control the tensile test carried out in a high temperature environment and the test environment conditions approaching space vehicle condition consistent.

For flexible performance materials generally include ground simulation test method T-peel method, 90 ℃ peel method, 180 ℃ peeling method, Bell peel (floating roller peel) method, and the like climbing drum peel method, etc. A relatively common and easy to operate method is T-peel test method that never ends glued start peeling force, making the laminate along the gum line and gradually stripped under load. According to the national standard GB-2791-81 and draw contour method, the principle of laminated peel strength test can be obtained:

$$\sigma_T = \frac{F}{B} \tag{2}$$

Where the T-peel strength, KN / m; F is the average peel force, the unit is N, B is the width of the sample separation unit m. Peel test methods whereby the shear strength of the material in performance. As the large temperature difference between daytime and night in near space. Ground environment simulation requires high temperature humidity environmental chambers conducted. Near space temperature usually ranges from -65℃~55℃ and atmospheric pressure is in the range of 4500Pa~1atm. If it requires simulating the real material conditions of service under the alternating load, high and low temperature test material is applied. Also it need to require to control the cycle of alternating high and low due to the real conditions of the cycle is 24 hours, even skin material withstand high and low temperature load, performing to analyze the mechanical properties of the long voyage skin material changes.

Weather resistance and air tightness of ground simulation test method

The ground simulation of natural weathering cost a long time, a high testing cost, and the choice of the natural environment need to be close to the climate characteristics of the space environment near space. While taking it into account that the long-endurance service material characteristics, excellent weathering properties of the material is required, therefore weathering test must be carried out in service of the material. Usually under laboratory conditions, a single artificial ground simulation test were tested by UV aging characteristics, effects of ozone aging characteristics, infrared light and other radiation on the mechanical properties of the material. Such as ozone aging test selection model BH-OZ2000 testing machine, testing requirements in line with the national standard GB/T 7762-2003, etc. The test machines can observer status at any time inside the box of the test material. Its technical parameters tested in the following table. Due to the special nature of the airship envelope material commonly used in the stratosphere and extremely complex environment, the envelope material is in mechanical load, while inevitably be in stratospheric environment of multiple factors.

Table 2 Parameter range of environmental simulation test

Temperature Range	0℃～70℃	Ozone density	0~500pphm，0～100ppm or more（1ppm=100pphm）
Temperature Fluctuation	±0.5℃	Airflow velocity	12-16mm/s
Humidity Range	≤65% R.H	Fixture category	Suitable for static stretching; dynamic tensile

And ultra-low temperature , thermal radiation , thermal stress fatigue , light aging , ozone, ultraviolet radiation aging , plasma impact, etc.) coupled synergy of tearing skin material damage and failure also has accelerated the impact effect, but a single mechanism and a variety of environments effect mechanism features investigation is little. At present, there are some relevant test methods including reinforcing fibers for thermal aging skin material and mechanical properties, the Australian Defense Science and Technology Organization using differential scanning calorimeters(DSC) and thermo-mechanical mechanical analysis (TMA) study Kevlar49 high temperature properties of fiber bundles and Nomad fiber bundles, concurrent happens now when the high temperature 440 ℃ thermal degradation phenomena, and studied the fiber bundle under ultraviolet light and heat and the bending fatigue mechanical properties.

Conclusion

(1) This paper studies the environmental characteristics of the long-time flying near space airship, and the ground simulation test methods are summaried up for physical geometry measurement of the airship envelope material, including the test methods under weathering characteristics of mechanical strength and single / multiple coupling mechanisms. The envelope tests under multi-mechanism coupled environmental factors could truly reflect actual working conditions in the stratospheric space.

(2) The envelope material testing methods under the true conditions are analyzed involving high and low temperature, ozone, thermal stress fatigue in near space environment. And the prospects for various types of test problems and further research is discussed. For lack of multi-mechanism coupled tests, the airship envelope material is usually designed and used with a very high factor of safety, to avoid the influence of various environmental factors on performance of the NSA envelope, and the coressponding relationship between the different coupling test methods is obtained.

Based on 3-D modeling and value simulation of the intake system in CNG

LI Jing-hua, Li Jiang-jiang
TianJin Vocational Institute,Tianjin,300410,China

Keywords: intake air system;GAMBIT modeling; FLUENT simulation;analysis of fluid flowing quality

Abstract. The structure of the air intake system directly affect the combustion and heat load in each cylinder. In this paper, using the CFD experience can look the intake pipe gas flow as a 3-D compressed steady flow. It is easy to built a 3-D model grids with the help of GAMBIT software .Using the FLUENT soft software ,it is reasonable to get the the fluid velocity distribution in flow field , and calculate the fluid flowing quality at the exit of manifold, as well as analyze the inhomogeneity of the inlet air.

Introduction

CNG gas engine is an improved engine ,which is increased gas mixing injector device between the intake manifold and the cylinder head to achieve mixing outside the cylinder. Based on the main intake manifold air ,ECM will calculate the average allocation air for each cylinder. According to the intake air of each intake manifold ,the propel fuel will be injectd into the corresponding maniford to form a pre-combustion mixture. On the contrary ,If the distribution of the mixed gas for each cylinder is not be uniform , then causing the difference combustion for cylinder which will lead to the combustion heat load .

Calculation model

Model building and meshing

Using the pre-processing software GAMBIT ,it is easy to build a three-dimensional flow model of the intake system based on CAD .We can consider the internal cavity of intake system as the outer boundary of the computational model, including the construction of the intake manifold, intake manifold and cylinder cover, also including inlet air flow throughout the channel. Entrance model is the inlet of main intake manifold and the outlet is the inlet terminal. With the applying of GAMBIT software ,the three-dimensional model can be meshed as unstructured tetrahedral meshes. The front surface of the inlet could be set as mass flow inlet boundary,and the outlet face is set as pressure outlet boundary, others are wall boundary. Calculation model shown in Figure 1.1, the outlet 1-6 correspond to the 1-6 intake of cylinder.

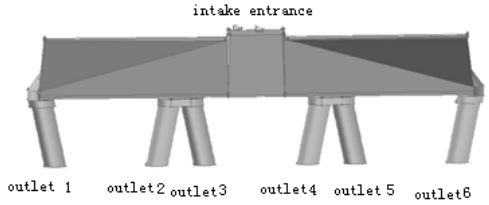

Fig1.1 The calculated model of the air inlet system

The selection of calculation model and boundary conditions

The flow of gas in the intake system can be regarded as a three-dimensional compressible unsteady flow, conditions of turbulent flow. The Calculation mainly solve the continuity

equation, momentum equation, energy equation and turbulence equations. Because of variable of the compressible fluid density , we have to treat the gas as an ideal gas ,at the same time add the state of ideal gas equation that solving the problem. Turbulence model is still used the common standard $k-\varepsilon$ equations, the constant coefficients in the model is showed in Table 1.

Table 1 The coefficient of the standard $k-\varepsilon$ model

C_μ	$C_{\varepsilon 1}$	$C_{\varepsilon 2}$	$C_{\varepsilon 3}$	$C_{\varepsilon 4}$	σ_k	σ_ε
0.09	1.44	1.92	0.8	-0.33	1.0	1.3

Area boundary model includes outlet boundary wall and solid wall. Import using mass flow boundary conditions ,the estimation which is obtained according to the normal engine operating condition is that:the total mass flow of imported face is $0.28^{kg/s}$, turbulence parameters is $k=0.046m^2/s^2$, $\varepsilon=0.451m^2/s^3$,setting temperature is 300K, pressure is 101325^{Pa}. Export can use the boundary of outlet pressure, the pressure is set to 100^{KPa}, the temperature is set to 320K, turbulence parameters is $k=0.046m^2/s^2$, $\varepsilon=0.451m^2/s^3$ .Solid wall boundary is set to a constant temperature 320K , the velocity is use of no-slipping boundary condition.

The results of simulation and analysis

With the using of the FLUENT software , it is easy to get the result of calculating model based on three-dimensional numerical simulation. Meanwhile, results of the uniformity of induction system were analyzed.

The simulation results of air flow field and analysis

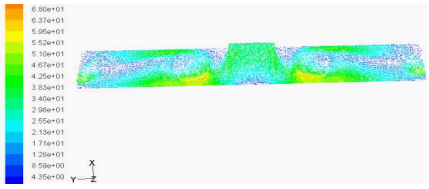

Fig1.2 Velocity vector of underside of the inlet

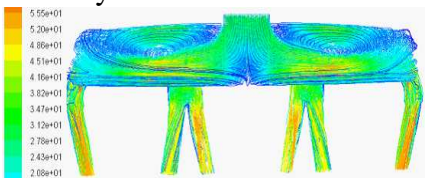

Fig1.3 The streamline of the air inlet system

Analysis of the figures 1.2 and 1.3, we can draw the characteristics of entire intake system: the flow of movement is symmetrical, symmetry plane is the central axis of the intake manifold inlet face. The velocity vectors of inlet pipe bottom shows that the flow velocity in the intake pipe is uneven.The right side of first cylinder intake manifold and the left side of the sixth cylinder intake manifold appear the larger low velocity zone at the same time,and the entrance of the third, fouth, fifth intake manifold show the some low velocity zone. It is not difficult to find these low flow areas exist reflow phenomenon,which caused increase of flow resistance and reduce of flow velocity. Figure1.3 shows that the low velocity zone have the backflow phenomenon,and in these regions due to reflow generate swirl. It can be seen from Figure 1.3 that flow rate of the first and sixth cylinder is the maximum. The third,four cylinder followed and the second, fifth cylinder is minimum. In order to more clearly show the entrance of each cylinder flow field, we made a enlarge figure of velocity vector of each cylinder intake entrance, Figure 1.4 and Figure 1.5.

Fig1.4 Velocity vector of intake manifold of 1-3 cylinder

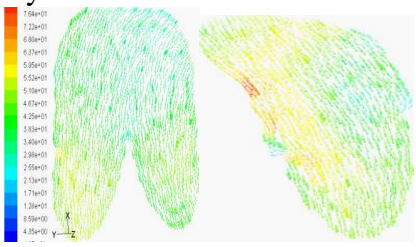

Fig1.5 Velocity vector of intake manifold of 4-6 cylinder

As can be seen from the enlarged views, the air speed of the first cylinder and sixth cylinder have greater speed with the same direction of velocity and outlet. The second cylinder and the third cylinder use the same intake manifold. The vector diagram shows that velocity vector in the tube is closer to the outlet direction of the third cylinder, the flow of the second cylinder actually change a direction. For this reason, the flow resistance of the second cylinder is slightly larger than the third cylinder. The flow relationship of the fourth and the fifth cylinder are the same as the second and the third cylinder.The flow direction of the fourth cylinder is closer to inlet flow, more smooth flow and flow rate greater. The outlet face of the mass flow rate calculated as shown in Table 2.

Table 2 Mass flow rate of each exit of the air inlet system

intake number	1	2	3	4	5	6
mass flow rate (kg/s)	0.050	0.044	0.046	0.046	0.044	0.050

Conclusion

This article analyses and simulates the CNG engine intake uniformity.What's more,established engine air intake system model containing intake pipe and inlet of the, using the FLUENT software study the intake inhomogeneity base on 3-d numerical simulation and getting the results of inlet mass flow rate of each cylinder.On the other hand, with analysis of intake inhomogeneity of the engine cylinder found that the problem about uniformity of engine air intake system is obvious,which caused the second and the fifth cylinder mixture abnormal, remains to be further improved.

The metabolic GM (1,1) prediction of the absolute gas emission quantity in a certain mine

Xiangyun Meng [a], Rihui Chen [b], Shibin Wang [c]

Faculty of Land Resource Engineering, Kunming University of Science and Technology, Kunming 650093, China

[a]yan761415498@163.com,[b]chenrihui555@126.com, [c]wsb18288667554@163.com.

Keywords: the gas emission quantity, GM (1, 1), the GM (1, 1) metabolism model

Abstract: the paper briefly discusses the gas emission prediction method, puts forward the grey model prediction method combined with domestic actual, and according to the material of the absolute gas emission quantity of the mine in the past decade, sets up the GM (1, 1) metabolism model. By solving the model, predictions are given, and the results are tested. The paper draws the predicted value of the absolute gas emission quantity over the next five years, analyzes the overall trends and gives general advice.

Introduction

Gas disaster is the head of "five natural disaster" in the coal mine production, often leads to major malignant accidents, has an impact on mine sustainable healthy development, and results in a very bad consequence on the society and national economy. In recent years, with a surge in demand of coal resources and the degree of mechanization of mining industry to be improved continually, the mine gas emission quantity has a sharp rise to threaten the coal production safety seriously. Therefore, it is particularly important to strengthen the pre-mining and pre-pumping of gas in the coal mine, the forecast of gas emission quantity, and the management of gas.

The application status of the prediction of gas emission quantity at home

For a long time, the coal mine in China utilizes mainly the mine statistical method to predict the mine gas emission quantity [2], but the mine statistical method requires a huge enough sample space, a similarity between the predicting regional and the reference area in mining technical conditions and geological conditions, while its forecast range is very restricted. But the mine production is a extremely complicated system engineering, and with the extension of mining, geological conditions and technical conditions of each seam, development methods, and mining method are always changing to lead to a dynamic change of the mine gas emission quantity, which seriously influence the application range and prediction accuracy of the mine statistical method.

In this case, to explore a new path which is able to accurately predict the gas emission quantity is imperative. By chance, the grey system theory is a subject that lays particular emphasis on the connotation and excludes external uncertain factors to find out the actual rule, so it can be well applied to the mine gas emission quantity prediction. In addition, the development coefficient of the gray model reflects the development trend of the corresponding sequence (the absolute gas emission quantity) accordingly to solve the dynamic change problem of the mine gas emission quantity. And the gray system requires only a few data sample size, only with the mine gas identification data over the years, can predict the gas emission quantity in the future several years, which makes it more practical operability.

The establishment of the GM(1,1) model

The grey system theory is an emerging discipline which was founded by a famous scholar Professor Deng Julong in China in 1982, which takes "partial information known, some information unknown" "uncertain system" as the research object, and through the generation and development of the "part" of the known information, achieves the precise description and understanding of the world[3]. Among above, the GM (1, 1) model is the core of grey prediction and it is a first-order differential equation, in which a single variable is predicted and whose discrete time response function presents exponential law.

The data processing.

A. Let the original time data sequence $X^{(0)} = \left(x^{(0)}(1), x^{(0)}(2), \cdots x^{(0)}(n)\right)$;

B.To $X^{(0)}$, do 1-AGO, in which $x^{(1)}(k) = \sum_{i=1}^{k} x^{(0)}(i), k = 1, 2\cdots, n$,

So $X^{(1)} = \left(x^{(1)}(1), x^{(1)}(2), \cdots x^{(1)}(n)\right)$

C. The mean generation with consecutive neighbors of $X^{(1)}$, in which $z^{(1)}(k) = 0.5x^{(1)}(k) + 0.5x^{(1)}(k-1)$, so $Z^{(1)} = \left(z^{(1)}(1), z^{(1)}(2), \cdots z^{(1)}(n)\right)$;

The establishment of the model.

A. The establishment of differential equation. What the albino differential equation of the dynamic model $GM(1,1)$ of first-order differential equations with a variable is: $\frac{dx^{(1)}}{dt} + ax^{(1)} = b$

In which, a, b are parameters to be identified, and -a is the development coefficient that reflects the development trend of $\hat{x}^{(1)}$ and $\hat{x}^{(0)}$; b is the grey action quantity that reflects the change relationship between data.

So what its time response function is: $\hat{x}(k+1) = (x^{(0)}(1) - \frac{b}{a})e^{-ak} + \frac{b}{a}$

B. The calculation of parameters. What the least square estimation of the parameter column $\hat{a} = \left(a, b\right)^T$ is: $\hat{a} = (B^T B)^{-1} B^T Y = (a, b)^T$, In which, what "B, Y" respectively is:

$$B = \begin{bmatrix} -z^{(1)}(2) & 1 \\ \vdots & \vdots \\ -z^{(1)}(n) & 1 \end{bmatrix} \qquad Y = \begin{bmatrix} x^{(0)}(2) \\ \vdots \\ x^{(0)}(n) \end{bmatrix}$$

C. The calculation of the simulating value. We can work out the simulation value $\hat{X}^{(1)}$ of $X^{(1)}$ by using the time response type of model. To $\hat{X}^{(1)}$, do IAGO to get $\hat{X}^{(0)}$, in which: $\hat{x}^{(0)}(k) = \hat{x}^{(1)}(k) - \hat{x}^{(1)}(k-1)$

D. The accuracy test. Whether he gray prediction model GM (1, 1) established above meets the accuracy requirements remains to be tested. With the grey theory model, we usually have three kinds of methods [4]: the method of test for the residual size, the method of test for the correlation, the method of test for the posterior error reification. The paper adopts the method of test for the residual size used frequently to test the model.

Let the residual $\varepsilon(k) = x^{(0)}(k) - \hat{x}^{(0)}(k)$;

Let the relative error $\Delta_k = \left|\varepsilon(k)\right| \Big/ x^{(0)}(k)$;

Let the average relative error $\overline{\Delta} = \frac{1}{n}\sum_{i=1}^{n} \Delta_i$.

According to Δ_n and $\overline{\Delta}$, we calculate the accuracy grade with the table 1. The larger value in Δ_n and $\overline{\Delta}$ is usually used to determine the accuracy grade by being compared with the table 1. The accuracy grade seen in the table 1[3] below:

Table 1 The accuracy grade in testing

The accuracy grade	first	second	third	fourth
The relative error	<0.01	0.01-0.05	0.05-0.10	>0.10

The metabolic GM (1, 1)

The general GM (1, 1) model requires less data, which will to some extent its practical operability and yet will also has some influence on the accuracy of the GM (1, 1) model making the long-term prediction. And the paper is planned to make predictions about the gas emission quantity in the next five years, which has a longer length, so we need optimize the general GM (1, 1) and then we raise the metabolic GM (1,1).

The metabolic GM (1, 1): we let the original data sequence $X^{(0)}$ =($x^{(0)}$(1), $x^{(0)}$(2),…, $x^{(0)}$(n)), introduce new information $x^{(0)}$(n+1)/ $\hat{x}^{(0)}(n+1)$, clear away old information $x^{(0)}$(1), declare that the GM (1, 1) established by $X^{(0)}=\left(x^{(0)}(1),x^{(0)}(2),\cdots x^{(0)}(n+1)\right)$ / $\hat{x}^{(0)}(n+1)$) is the so-called metabolic GM (1, 1).

From the perspective of the predicted, the metabolic GM (1, 1) is a better model. As the system evolves, the significance of the old data will be being reduce, and when the new information is constantly added, we get rid of old information in time to make the sequence better reflect the characteristics of the system in the present[4].

The prediction analysis of a certain mine gas emission quantity based on the metabolic GM (1, 1)

The measured data f a certain mine gas emission quantity in nearly a decade is shown in table 2:

Table 2 Statistics of a certain mine absolute gas emission quantity

years	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
The absolute gas emission quantity (m^3/min)	40.09	43.47	41.66	32.86	44.06	38.74	49.67	46.38	49.67	46.15

The establishment of the GM (1,1)

A. Let the original time data sequence $X^{(0)}$ come from the table 2, so

$$X^{(0)}=\left(x^{(0)}(1),x^{(0)}(2),\cdots x^{(0)}(10)\right)=(40.09,\ 43.47\ldots\ 46.15)$$

To $X^{(0)}$, do 1-AGO,so $X^{(1)}=\left(x^{(1)}(1),x^{(1)}(2),\cdots x^{(1)}(10)\right)$=(40.09,83.56,…,432.75)

The mean generation with consecutive neighbors of $X^{(1)}$, so

$$Z^{(1)}=\left(z^{(1)}(1),z^{(1)}(2),\cdots z^{(1)}(n)\right)=\left(61.83,\ \ldots\ ,409.68\right)$$

B. To figure out the parameter column $\hat{a}=(a,b)^T$ by the least square estimation.

$$\hat{a}=(B^TB)^{-1}B^TY=(a,b)^T=(-0.0262,\ 37.637)^{\mathrm{T}}$$

What its time response function is:

$$\hat{x}(k+1)=(x^{(0)}(1)-\frac{b}{a})e^{-ak}+\frac{b}{a}=1478.0774\exp\ (0.0262k)-1437.987$$

C. To figure out $\hat{X}^{(1)}$, and then do IAGO to obtain $\hat{X}^{(0)}$, so

number	1	2	3	4	5	6	7	8	9	10
the simulating value	40.09	39.20	40.24	41.30	42.40	43.52	44.68	45.86	47.08	48.33

D. The accuracy test. We can work out "Δ_{10}= 0.0471， $\overline{\Delta}$=0.0846", comparing it with the table 1, to know that its accuracy is level 3. Even so, the paper only forecast the next data, so the model can be used.

The prediction of the metabolic GM (1, 1)

A. To predict the absolute gas emission quantity in 2013 by the model in "(1)",

So $\hat{x}^{(0)}(11)$=49.61

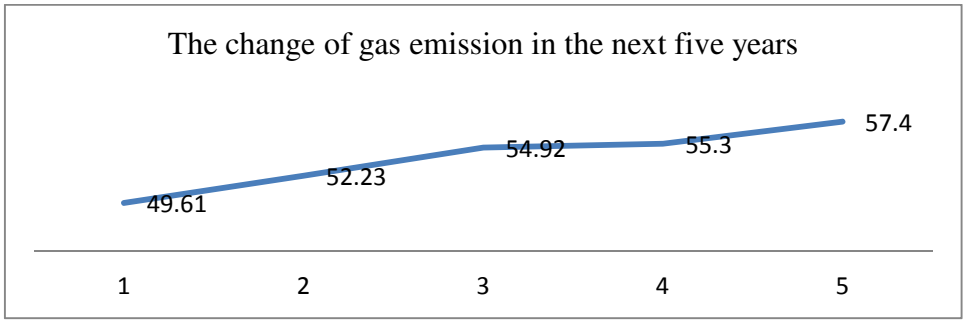
B.To $X^{(0)}=\left(x^{(0)}(1),x^{(0)}(2),\cdots x^{(0)}(10)\right)$, we introduce new information $\hat{x}^{(0)}(11)$, clear away old information $x^{(0)}(1)$, to get new original data sequence:

$$X^{(0)}=\left(x^{(0)}(2),x^{(0)}(3),\cdots x^{(0)}(11)\right)=(43.47,\ 41.66\ldots\ 49.61)$$

Putting $X^{(0)}$ into (1), we can predict the absolute gas emission quantity $\hat{x}^{(0)}(12)$=52.23 in 2014, meanwhile Δ_{11}= 0.0180， $\overline{\Delta}$=0.0784,comparing it with the table 1, know that its accuracy is level 3.

C. To repeat B. we are able to get respectively the prediction of the absolute gas emission quantity in 2015, 2016, 2017, so $\hat{x}^{(0)}(13)$=54.92， $\hat{x}^{(0)}(14)$=55.30， $\hat{x}^{(0)}(14)$=57.40

To analyze the absolute gas emission quantity predicted in the next five years.



From the figure, we obtain that the absolute gas emission quantity in the next five years remains increased by years. Therefore, formulating the mine ventilation system improvement program, arranging the pre-mining and pre-pumping of gas and choosing the coal mining method, the mine should take into account the needs of gas drainage, with the permission of economic and technical conditions, prefers to set aside the operational space of gas drainage.

Conclusion

With the metabolic GM (1, 1) to predict, while at first the accuracy of Δ_k and $\overline{\Delta}$ is level 3, the accuracy presents both a declining trend in metabolism, especially Δ_k reaching level 1 later, which shows that the metabolic GM (1,1) predicting the absolute gas emission quantity in a period of time is able to obtain a more reliable result.

With the deepening of mining level, expansion of mining area and mining mechanization degree increasing, and the growth of coal output, the absolute gas emission quantity is increasing year by year. Therefore, when the mine makes gas control measures for a period of time, it is applicable to take the metabolic GM (1, 1) model as the mine absolute gas emission quantity prediction model, which is able to reflect the changing dynamics and the general trend of the mine gas emission quantity, so its prediction results has an important reference value for the gas management.

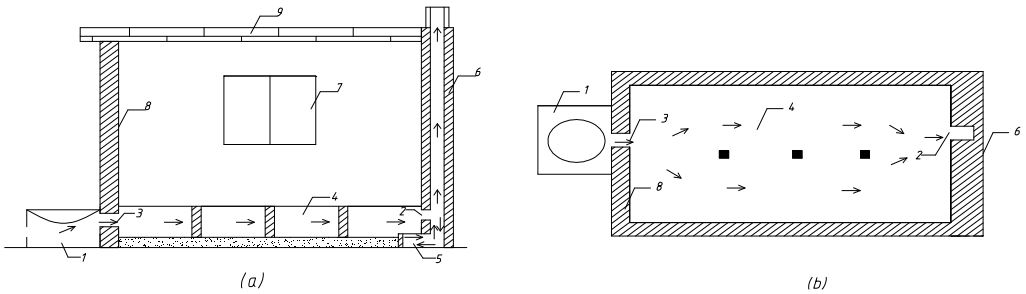
Key words: Chinese kang, Ventilation, Heating, Chimney, Wind tunnel, Numerical simulation.

Abstract. In the northern part of China, the heating system of the Chinese *kang* occupies a significant proportion of usage, particularly during the winter. To achieve better heating effect, this article explored the wind tunnel (commonly known as the "dog hole") of the Chinese *kang* in the Northern area. The paper conducted three experiments, established a two-dimensional mathematical model on the flow of high temperature gas in the chimney, utilized the FLUENT software to simulate the flow, and analyzed the inlet flow of the chimney flue and effect of wind tunnel on the heating system of Chinese *kang*. Wind tunnel was found to prevent natural reversed wind effectively and reduce the influence of outside wind.

Introduction

Chinese *kang* is a typical furnishings in northern China. In previous years, it was used by people to withstand the cold temperature during winter. According to the local custom, different local people have built different *kang* structures, and constantly innovated the original foundation. With an optimized flue, the *Zaotang*, *kang* wall, and other parameters enhanced thermal efficiency and reduced fuel consumption[1-2]. Generally, the Chinese *kang* is composed of a stove, *kang*, and chimney. The stove transmits hot gas to *kang* by fuel burning. Then, the *kang* transmits the gas to the room to increase the temperature indoor, and the chimney finally emits the gas outdoor[].The specific structure of Chinese *kang* is shown in Fig. 1.



1 Stove 2 Import of chimney 3 Import of *kang* 4 *Kang* 5 Wind tunnel 6 Chimney 7 Window 8 Wall 9 Roof

Fig. 1. Structure of Chinese *kang*

The wind tunnel (commonly known as the "dog hole") mainly alleviates the reversal of air in the chimney. When reverse airflow enters the chimney, the wind tunnel avoids the fuel gas from turning to the *kang* and stove, as such phenomenon causes insufficient burning of fuel and causes the gas to flow to the room, which may have adverse health effects [3-4]. This article uses the FLUENT software to simulate the flow inside the chimney, and analyzes the effects of wind tunnel on ventilation and heating.

Experiment

We selected a residential building in northern China to obtain data.

The size of the house was 4 m × 3.5 m × 3 m. The size of the *kang* was 3.3 m × 2 m × 0.6 m. The size of the wind tunnel was 0.3 m × 0.5 m × 0.2 m. The size of the adobe was 0.3 m × 0.5 m × 0.1 m.

The wall was made up of approximately 200 mm concrete bricks.

The equipment used in this experiment included a drilling rig (CF-166), stopwatch, electronic thermometer (KT-300), anemograph (475AV), and pitot tube.

To study the effects of different forms of chimneys on the ventilation and heating, we divided the study into three experiments to determine the initial velocity and temperature of the gas. Through the hole drilled in the inlet of the chimney, the velocity and the temperature were measured by using electronic thermometer, stopwatch, anemograph and pitot tube per minute. First, we measured both under condition of cooking in stove-fire，the velocity and temperature at point 2 in Figure 1 (outlet of *kang*) was measured per minute. Second, we measured velocity and temperature in the foundation of the first group, in which the amount of constant wind enters from the chimney outlet (set to 2.6 m^3/s), thereby determining the data of point 2. The third measurement was based on the first and second groups, conducted by blocking the wind tunnel with adobe, and carrying on to point 2 on temperature and velocity.

Experimental data allowed the plotting of the figures on the outlet velocity. The temperature of *kang* was calculated with Matlab (Figures 2 and 3). Figure 3 shows that the velocity of point 2 initially increases quickly, reaching a peak after 15 min, then gradually decreases. The velocity of normal ventilation was higher than when in air drums. The velocity with wind tunnel was higher than without it. Figure 2 is to study the effect of wind tunnel on the temperature of *kang* and indoor, and it shows a positive correlation between the trend of temperature and velocity with time.

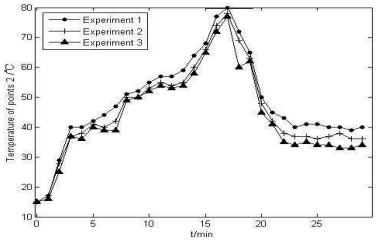


Fig. 2. Temperature of chimney inlet (2 points)

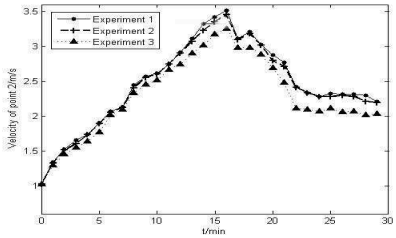

Fig. 3. Velocity of chimney inlet (2 points)

Combined with the measured experimental data, the experiment provided reference data for the inlet boundary condition of mathematical modeling.

Mathematical modeling

Based on the selected data, we established three 2-D mathematical models with GAMBIT, and then divided the mesh and exported the files to FLUENT. In this experiment, the high temperature gas was a viscous incompressible fluid. The *kang* was confined sufficiently. We used K-epsilon turbulence model to study fluid movement [5]. Finally, the boundary condition of inlet velocity, along the horizontal direction, was determined, with 3.1 m/s size, and 338.15 K (65 °C) temperature. (The high temperature gas density is ρ =1.39 kg/m^3, and the air density is ρ_0=1.2 kg/m^3).

We designed the model to cover conservation equations of mass, momentum, and energy equations [6].

The equation for the conservation of mass is as follows:

$$\rho \frac{\partial v_i}{\partial x_i} = 0 \tag{1}$$

For an incompressible fluid, $\frac{\partial \rho}{\partial t} = 0$.

Conservation of momentum equation:

$$\rho\frac{\partial v_i}{\partial t}+\frac{\partial}{\partial x_j}\left(\rho v_i v_j\right)=-\frac{\partial p}{\partial x_i}+\mu\frac{\partial^2 v_i}{\partial x_j^2}+\rho g_i \tag{2}$$

p is the static pressure; μ is the dynamic viscosity; g_i is the volume force of gravity.

Conservation of energy equation

$$\rho\frac{\partial E}{\partial t}+\frac{\partial}{\partial x_j}[\mu_j(\rho E+P)]=\frac{\partial}{\partial x_j}(\eta_{eff}\frac{\partial T}{\partial x_j})-\sum_j h_j J_j+u_j(\tau_{ij})_{eff}+S_h \tag{3}$$

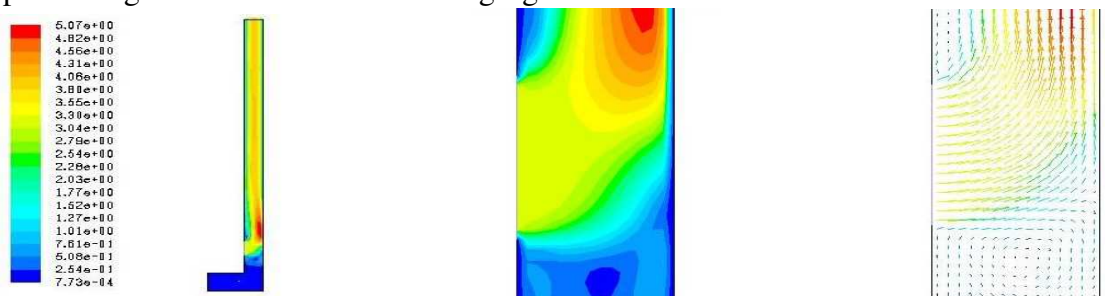
E is the thermodynamic energy per unit mass of the fluid;

$\eta_{eff}=\eta_t+\eta$ is an effective thermal conductivity，η_t is the viscosity of turbulent，η is the dynamic viscosity caused by molecular diffusion;

τ_{ij} is stress tensor; $J_{j'}$ is the diffusion of j'; S_h is the chemical reaction of heat and other volumetric heat sources.

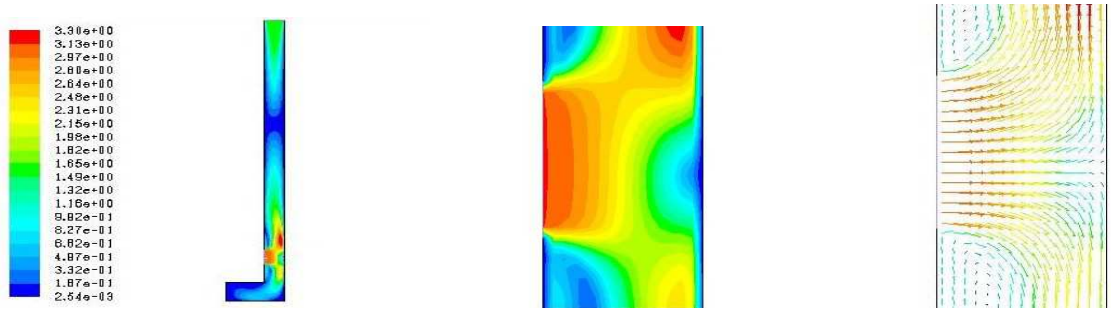
Results and discussion

We imported the figure of the chimney's flow model from FLUENT into TECPLOT for post-processing. We obtained the following figures：



(a) Model of overall chimney velocity (b) Velocity distribution of inlet (c) Velocity vector of inlet

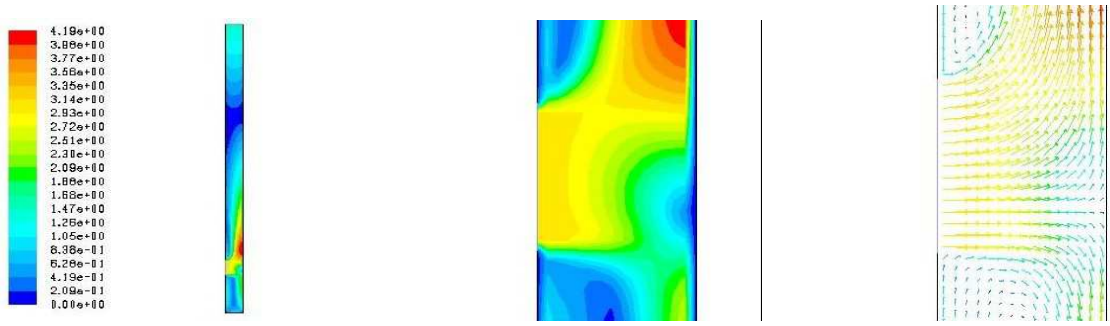
Fig. 4. Flow model of normal ventilation in the chimney with wind tunnel



(a) Model of overall chimney velocity (b) Velocity distribution of inlet (c) Velocity vector of inlet

Fig. 5. Flow model of reverse ventilation in the chimney with wind tunnel

Figure 4 shows the flow model of normal ventilation in the chimney with wind tunnel. Figures 4 (b) and (c) reflect the motion of the gas at the inlet. High temperature gas by pressure moved upward from the inlet of the chimney, and a small part of the gas moved downward to the wind tunnel. Given the potential change, the speed initially increased, then decreased gradually, until and the trend stabilized. Shear forces were also in between the wall and flow gas in the process. Thus, the velocity of the gas close to the wall was less than that in the central chimney. The gas flowed outside from the outlet of the chimney.



(a) Model of overall chimney velocity (b) Velocity distribution of inlet (c) Velocity vector of inlet

Fig. 6. Flow model of reverse ventilation in the chimney without wind tunne

Figure 5 shows the flow model of reverse ventilation in the chimney with wind tunnel. According to the principle of conservation of energy, air flow was almost 2.6 m^3/s in the chimney inlet drums. After hot gas entered the chimney, part of the gas slowly went upward, which then sped up toward zero at a certain height. Another part of the gas moved downward to the wind tunnel, where the velocity reduced gradually. Thus, the wind tunnel prevented natural reversed wind and reduced the function of the outside wind.

Figure 6 shows the flow model of the reverse ventilation in the chimney without a wind tunnel. When using adobe block, the tunnel and drums enabled air flow of about 2.6 m^3/s (Figure 6). Then, the gas flowed downward to the bottom chimney, and after reaching the bottom, it moved up to the inlet of the chimney again. This kind of structure did not reduce the effect of the outside natural airflow, instead creating a part of gas backflow to the *kang*.

Conclusions

When the reverse wind flows into the chimney, on the one hand, the wind tunnel can decelerate the flow of the gas, thus weakening the reverse airflow at the outlet of *kang*. On the other hand, it can accelerate the burning of fuel, keep the *kang* in higher temperature, and maintain an ideal indoor environment. If the *kang* does not have a wind tunnel, with reverse airflow into the *kang*, the fuel of the stove is not fully burned, thereby transferring less energy from the stove to the *kang*. Hence, the temperature of the *kang* cannot reach the ideal level, thus reducing the quality of air indoor. Therefore, when constructing the *kang*, a wind tunnel should be built at the bottom of the chimney using bricks and adobe to prevent reverse wind.

Keywords: Swift satellite, Ultraviolet/Optical Telescope, HEASoft software, PKS 0537-441.

Abstract. The Ultraviolet/Optical Telescope (UVOT) which is one of three scientific instruments onboard the NASA-led Swift satellite provides simultaneous ultraviolet and optical photometric data. We present the installing procedures of HEASoft software and the detailed method for using the HEASoft in UVOT photometric data processions. We focus on the application of photometry processes, and present the photometry of Quasar PKS 0537-441. The analysis of the photometric data shows that this source has extreme variations in optical and ultraviolet bands and the shape of photometric flux curves in each band is excellently in agreement with each other.

Introduction

Over the last few decades, space instruments such as the Hubble Space Telescope, the Fermi Telescope and Swift Gamma-Ray Burst (GRB) satellite have created an infusion of scientific discovery, particularly in high energy environments. The Swift satellite rocketed into space in 2004 on a mission to study GRB and other transient or variable phenomena. As a multi-wavelength space observatory, Swift carries three instruments, the Burst Alert Telescope (BAT) [1], the X-ray Telescope (XRT) [2] and the Ultraviolet/Optical Telescope (UVOT) [3]. The primary research of the Swift is rapidly locates new GRB and then brings XRT and UVOT to bear on that location.

The UVOT instrument onboard Swift is a 0.3m aperture Ritchey-Chrétien reflector using a fast readout CCD detector capable of detecting low signal levels. These are photon counting devices which have a resulting image field of 2048×2048 pixels, covering a field of view of 17 × 17 arcmin^2. UVOT obtains the photometric data in ultraviolet and optical bands in parallel after the BAT trigger. Thereafter, the instrument executed cycled exposures through each of six color filters housed in a filter wheel, u, v and b in optical band together with uvw1, uvm2 and uvw2 in ultraviolet band [4]. The characteristics of these filters are shown in Table 1. The standard software suite, HEASoft, could provide excellent processing platform for the photometric data procession of GRBs. However, the official software installation and data analysis guide concentrate more emphases on generality and completeness but pay less attention to usability and pertinence. In this paper, we first present the installing procedures of software and provide methods for the procession of UVOT images. Then, we describe the photometric observations of Quasar PKS 0537-441 and present our conclusions.

Table 1 UVOT filter characteristics.

Filter	$\lambda_{central}$(Å)	FWHM(Å)	Filter	$\lambda_{central}$(Å)	FWHM(Å)
uvw2	1928	657	u	3465	785
uvm2	2242	498	b	4392	975
uvw1	2600	693	v	5468	769

Installing HEASoft Software

HEASoft is designed for the analysis of scientific astronomical observations at extreme ultraviolet, X-ray and Gamma-ray wavelengths. HEASoft 6.15.1 is the current version of HEASoft, which resolved some known issues and provides a more powerful data processing platform. The

corresponding source code distribution and individual Swift mission package must be downloaded from the website [5] before installing. The following are a description of the steps we took to install HEAsoft software on Fedora 20.

Step 1: Build environment and configure the software. Use the package manager ("yum") to install "gcc" , "gcc gcc-c++", "gcc gcc-gfortran", "ncurses-devel", "libXt-devel", "compat-gcc-34-g77" and "perl-ExtUtils-MakeMake" with root or administrator permissions. Unpack the downloaded file to create a directory named heasoft-6.15. Then go to the BUILD_DIR directory and set the relevant environment variable by executing "export CC=/usr/bin/gcc", "export CXX=/usr/bin/g++" and "export FC=/usr/bin/gfortran" and "export PERL=/usr/bin/perl".

Step 2: Install HEAsoft and set the environment variable. Starts the build process by executing "./configure >& config.out &", "make >& build.log &" and "make install >& install.log &" in order. These processions finally create an appropriately-named system-dependent directory i686-pc-linux-gnu-libc2.18 under heasoft-6.15.1/.

Step 3: Build the Swift Calibration Database (CALDB). The HEASARC'S Swift CALDB system which stores and indexes datasets associated with the calibration of the Swift instrument is essential for data reduction and analysis. Create a directory where the calibration data will be located and define the $CALDB environment variable with "export CALDB=/usr/local/caldb". Then, download the CALDB file from the website [6] and unpack the file in $CALDB directory..

Step 4: Install SAOImage DS9. DS9 is the terrific image viewer application for the fits, binary tables, multiple frame buffers, region manipulation, and many scale algorithms and colormaps ubiquitous in astronomy. Download the tar files and unpack in /usr/local directory by executing "tar -zxf ds9.linux.7.2.tar.gz". After this, type the command ds9 in a terminal window to start ds9.

Photometric Data Procession Method

The UVOT data can be described using three basic modes: Image, Event and Image & Event. Here, we consider the analysis of image mode data; in the further article, we consider how to deal with the Event mode data. The publicly available data can be downloaded from the HEASARC archive [7].

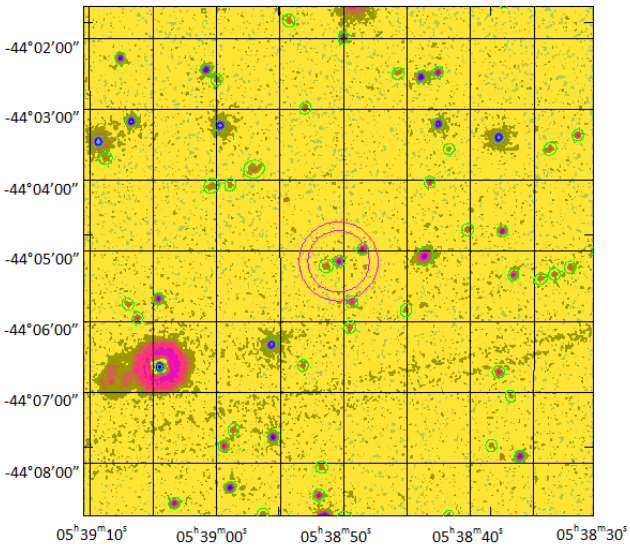

Fig. 1 UVOT image on November 24, 2005.The central target is Quasar PKS 0537-441.

Based on the Level 2 data contained in the HEASARC archive, we first make a general processing for position determination. Because of the extractors' capability to detect and measure extended sources, the source detection routine uvotdetect was designed to detect all sources in an UVOT image. Uvotdetect requires one mandatory input file containing one or more sky coordinates images and one optional one containing an array of weights for each pixel in the input image. To run uvotdetect the user provides a detection threshold which is measured in standard deviations above the noise. Uvotdetect has a single output file which contains a table of detected source positions, count rates and

1-sigma errors for each parameter. Run uvotdetect prompting for mandatory arguments for an u-filter sky image of Quasar PKS 0537-441 might be: "uvotdetect infile=0537.fits outfile=source.fits expfile=none threshold=3". Fig. 1 shows the UVOT image with all the detected sources marked on November 24, 2005. A description of Quasar PKS 0537-441 will be provided in the next section.

After finishing the general position determination, a tool named uvotsource returns information about the count rate from the source, the source's magnitude, and flux density information should be used to perform aperture photometry on a single source in a sky image. Loads the UVOT image in DS9 and specify the source extraction region and background region using region files. The source position returned by uvotdetect should be adopted, and the region files must be done with the fk5 coordinate system. That is recommendable to define a source aperture of radius 5 arcseconds to use for photometry. Run uvotsource for an u-filter sky image of Quasar PKS 0537-441 as: "uvotsource image=0537.gz srcreg=src.reg bkgreg=bkg.reg sigma=5 syserr=yes outfile=sources.fits". It is necessary to point out that uvotsource returns detection significance and coincidence-corrected count rate, magnitude and flux density in erg cm^{-2} s^{-1} A^{-1} with 1-sigma error. However, if the source is faint or the signal-to-noise is low, the uvotimsum tool should be used to sum extensions within an image.

Photometry of Quasar PKS 0537-441

We search for the publicly Swift data of Quasar PKS 0537-441 from the HEASARC interface [7]. Quasar PKS 0537-441, at redshift z=0.896, is a typical BL Lac object and has been observed for decades of years [8]. Many researchers have observed and studied this source and have found significant achievements. Recently, D'Ammando reported strong Gamma-ray variability and a harder-when-brighter behavior during multi-wavelength observations [9]. Based on the Swift data of Quasar PKS 0537-441, we follow the processing steps to do photometry. First, sum of all the slices using the uvotimsum tool. Second, extract the source position and then do target photometry using uvotdetect and uvotsource tool successively. Finally, use the E(B-V) value to correct magnitudes.

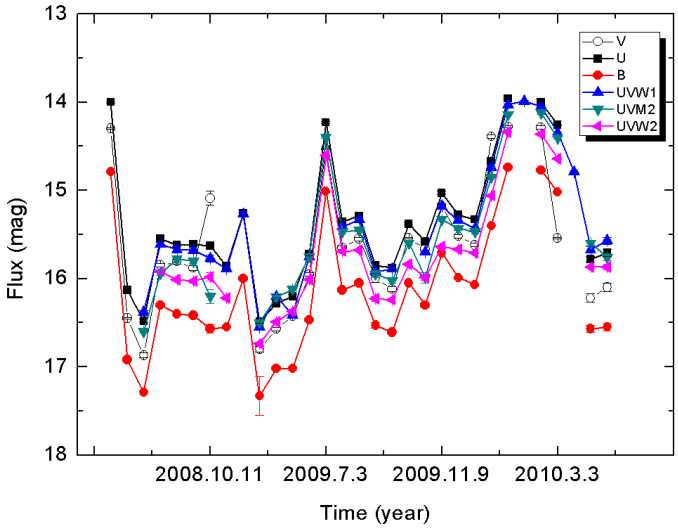

Fig. 2 Photometric flux curve of Quasar PKS 0537-441 in u, v, b, uvw1, uvm2 and uvw2 bands.

We carried out photometric observations of Quasar PKS 0537-441 from 2005 July to 2011 September in optical and ultraviolet bands. We performed photometric observations in Fig. 2. It is important to point out that all the photometric data are corrected for foreground Galactic interstellar reddening using the E(B-V) value at the query position [10]. As can be seen from Fig. 2, Quasar PKS 0537-441 has extreme variability in flux in optical and ultraviolet bands. More than 3 significant flux peaks appeared in the light curve during 6 years. These peaks correspond to large flare. Because of the lack of photometric data in the whole observation period, it is hard to carry out the periodicity just from the variation trend of the flux curve. Therefore, the particular method of signal processions, such as DCF, DFT and Wavelet analysis should be used to search for the periodicity in extra work.

Comparisons of the photometric flux curves, we can find that the shapes of photometric flux curves are similar and almost overlapping. Furthermore, the minimum optical variability time-scale of the BL Lac objects is longer than one more hour, and most are longer than 2 or 3 hours [11]. Hence, the quasi-simultaneous observations can be used to calculate the spectral index from a linear-square fit for spectral variation studying. Preliminary optical spectral variability analysis of Quasar PKS 0537-441 suggests that when the long-term flux variations increase, the optical spectra becomes bluer. The variation could be interpreted as changing of the jet viewing angle.

Conclusions

In this work, we take Fedora 20 Linux operating system as the platform to install HEASoft. First, build environment and configure the software, and then install HEASoft and set the environment variable. After the completion of the Swift CALDB building, install DS9 software finally. The detailed process and method of photometry are also presented. Specifically, the uvotimsum tool sums extension, the uvotdetect tool extracts the source position; the uvotsource tool does the photometry. Based on the photometric process and method, we present the optical and ultraviolet photometric data of Quasar PKS 0537-441 from 2005 to 2011. In our photometric data analysis, Quasar PKS 0537-441 has extreme variability, and the shapes of photometric flux curves are similar. What is more interesting is that whether there is an obvious time lags exist in optical and ultraviolet photometric flux curve. Once the time lag is determined, the more valuable information can be gotten for understanding the physical radiation mechanism.

Key Words: Gas Fractionation Unit, Process Simulation, PROII

Abstract: Considering the problem of the energy consumption in the gas fractionation unit, PROII process simulation software is used to calculate the gas fractionation unit and to analyze the effect of process parameters. On the premise of ensuring product quality, these parameters can reduce energy consumption, improve economic benefit.

1 INTRODUCTION

Gas fractionation unit [1] is a device, which can separate liquefied petroleum gas in fluidized catalytic cracking unit into various fractions. Gas fractionation unit is mostly distillation column, the most energy has been consumed by the distillation process in the petroleum refining and chemical enterprises [2-3]. Therefore, the biggest problem in the control optimization is to select the best operating conditions and improve plant economic efficiency [4].

300 thousand tons per year of depropanizer column is the object in this paper. According to the problem of large energy consumption, PROII [5] process simulation software which was developed by SIMSCI company of American is used to simulate the depropanizer column. On the premise of ensuring product quality, various parameters is used to analyze the effect of column, and production device for energy conservation is achieved finally.

2 DEPROPANIZER COLUMN

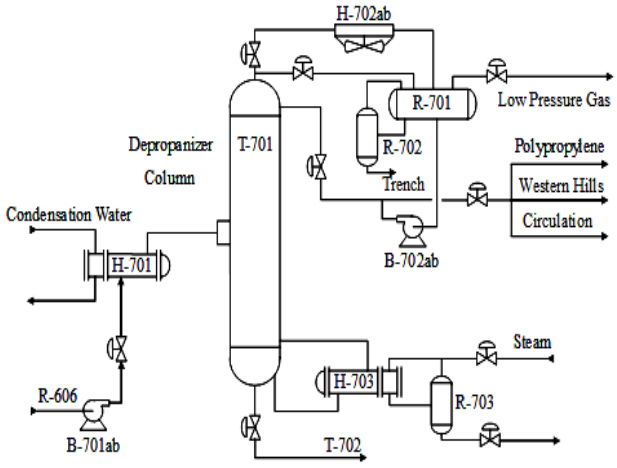

Fig. 1 Process flow diagram of depropanizer column

Liquefied petroleum gas(R-606) by a feed pump (B-701ab) is fed into the feed preheater (H-701), and sent to the depropanizer column (T-701) after heating. The reboiler (H-703) is heated by 1.3MPa (Gauge) steam. Carbon three fractions which are outflowed from the top of column are entered into the condenser (H-702ab), and then sent into reflux tank (R-701). By the reflux pump (B-702ab), part of the condensate is flowed back into column, part of it is sent to storage device or polypropylene unit as finished produce. The bottom of the column of the materials is fed into isobutene column (T-702), as in figure 1.

3 PROCESS SIMULATION

In PROII, equation of state of Soave-Redlich-Kwong is used to calculate the thermodynamic model. Lee-Kesler is used to calculate the liquid density. Pumparound is used for the top of the column. The iterative algorithm chooses Enhanced I/O. Actual measured values are compared with simulated values, as in table 1.

Table1. Actual Measured Values and Simulated Values of Operating Parameters

Operating Parameters	Control Targets	Measured Values	Simulated Values
Feed Temperature/℃	—	40.63	40.63
Top Temperature/℃	31-46	40.37	38.9
BottomTemperature/℃	75-115	96.9	95.3
Top Temperature/MPa	1.40-1.80	1.60	1.60
Content of C4 inTop/%	≤2	0	0.01
Content of C3 in Bottom/%	≤2	0	0.01

Table 1 shows that the simulated values of operating parameters and product quality are basically consistent with the actual values. It illustrates that the calculation of using the thermodynamic equation and the establishment of simulation processes have higher credibility.

4 SIMULATION ANALYSIS

4.1 Feed Temperature

In the case of the reflux rate unchanged, the feed temperature has an effect on the energy consumption in the entire process, as in table 2.

Table2. Feed Temperature and Energy Consumption

Cycle Number	Temperature ℃	C-Duty GJ/Hr.	H-Duty GJ/Hr.	Liquid Fraction
1	40.6300	-12.3227	15.0431	1.000
2	65.0380	-13.5141	14.1361	0.9999
3	66.1858	-14.0647	13.7938	0.9004
4	67.3336	-14.6542	13.4979	0.8027
5	68.4814	-15.2726	13.2316	0.7059
6	69.6292	-15.9185	12.9887	0.6092
7	70.7770	-16.5924	12.7647	0.5120
8	71.9248	-17.2970	12.5571	0.4136
9	73.0726	-18.0340	12.3630	0.3133
10	74.2204	-18.8.44	12.1808	0.2110
11	75.3682	-19.6075	12.0092	0.1064
12	76.5160	-20.4395	11.8481	8.8008E-05
13	77.6638	-20.4826	11.8215	0.0000

According to the table of data, actual working, bubble point and dew point conditions of energy consumption and cost data are calculated, as in table 3.

From the table3, the operating cost has reduced from 1240.31 Yuan per hr. to 1053.98 Yuan per hr. if the feed temperature can be raised to dew point. 15.02% of the saving extent can be reached, the effect is very obvious.

Table3. Energy Consumption and Cost

Feed Temperature（℃）		40.630	65.0380	76.5160
C-Duty	(GJ/Hr.)	-12.3227	-13.5141	-20.4395
Water/Cost	(T/.,Yuan/Hr.)	147.19/88.31	161.42/96.85	244.14/146.48
H-Duty	(GJ/Hr.)	15.0431	14.1361	11.8481
Steam/Cost	(T/,Yuan/Hr.)	7.68/1152	7.22/1083	6.05/907.5
Total Cost	(Yuan/Hr.)	1240.31	1179.85	1053.98

4.2 Feed Location

For multi-component distillation column, feed location is also a critical operating parameter. Reflux ratio,condenser duty and reboiler duty has been changed along with the feed location, as in figure 2 and figure 3.

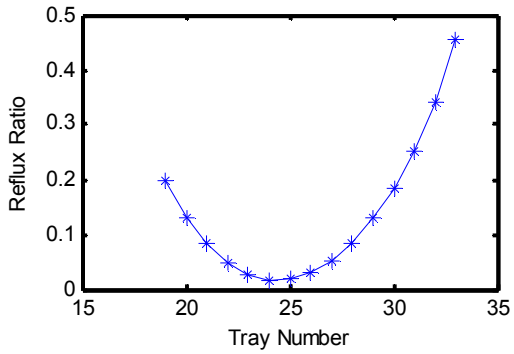

Fig.2 Change of reflux ratio

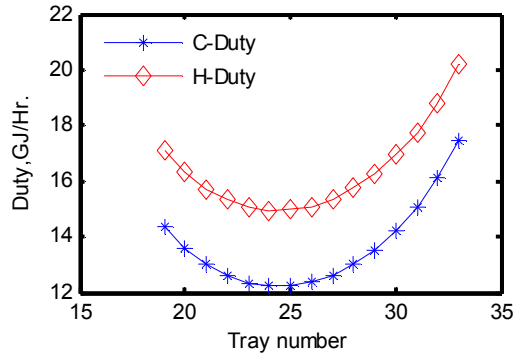

Fig.3 Change of duty

From the above figures, when the feed location in the twenty-fourth tray, reflux ratio, condenser duty and reboiler duty has reached minimum value. Condenser duty has reduced from12.3227 GJ/Hr. to 12.2128 GJ/Hr.. Reboiler duty has reduced from15.0431 GJ/Hr. to 14.9347 GJ/Hr..

4.3 Product Output of The Top

According to the material balance, the product quality has been changed by the product output of the top, in figure 4.

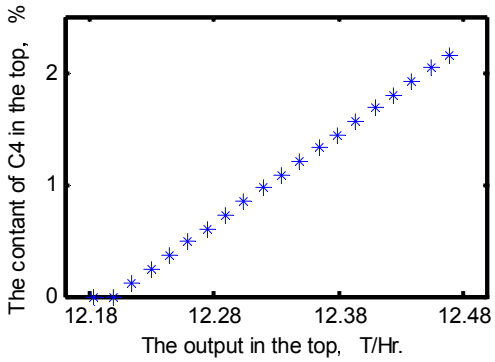

Fig.4 Changes of carbon four contents in the top

Figure 4 shows the relationship between product output and carbon four content in the top of the depropanizer column. With the increase of product output, the purity of propane has declined, the content of carbon four has obviously increased, and the problem of the high purity of propane has been solved. But continued to increase the output, it will lead to a substandard product. Therefore, the product quality is just standard by adjusting of product output, the unnecessary economic losses can be reduced.

5 CONCLUSION

According to the depropanizer column's technical characteristics, PROII software is used to simulate the column, the simulation values are basically consistent with the measured values. Through the analysis of the feed temperature, the feed location and the product output of the top, the column of the total energy consumption has been reduced, the industrial economic benefit has been improved.

Design and simulation of airborne circular omni-directional slot antenna

Luo REN[1,a], Yongzhong ZHU[1,b],Dan SU[1,c],Xin DENG[1,d]

[1] Department of Information Engineering, Engineering University of CAPF, Xi'an 710086, China

[a]1587904030@qq.com, [b]bsbs1980@sina.com, [c]sudan19901021@126.com, [d]1558125018@qq.com

Keywords: airborne, circular slot antenna, gain, frequency.

Abstract. The airborne omni-directional antenna must not only satisfy the indicators of omni-directional horizontal requirements, but also have conformal shape with the surface of airplane. The common monopole antenna and microstrip antenna can not meet the above requirements. Under the background of the airborne antenna miniaturization and conformal demand, this article designs a kind of airborne circular slot antenna. The structure of the antenna is simple, which meets pattern VSWR < 1.4 bandwidth of 350 MHz to 376 MHz and meets pattern VSWR < 2 bandwidth of 338 MHz to 438 MHz .Its maximum gain within the operating frequency range can be 4.205 dB .

Introduction

In aircraft applications, there are very strict requirements for airborne antenna: airborne antenna should not only meet all kinds of electrical indicators requirements and environmental requirements, but also meet the conformal design with the aircraft[1]. With the continuous development of technology, the microstrip antenna, the slot antenna and the monopole antenna become the main three types of airborne antenna[2]. For common microstrip antenna,though it can achieve the conformal design with the body,it can't form a bearing surface to the direction of the diagram.For monopole antenna,though it can achieve omni-directional pattern, it is hard to realize the conformal design[3]. Based on the research of this problem,this article designs an airborne ring slot antenna model, and the model by HFSS software simulation optimization finally obtains the ideal result. When the slot antenna is used on the surface of fast flying object ,it cannot introduce additional air resistance and it can hide the antenna itself[4]. Especially it can fully fit in the conformal installation of carrier and surface[5], realize the carrier surface smooth with no bump, and well meet the requirements of the airborne antenna.

Antenna Design

A. The theoretical analysis. The main advantage of the ring slot antenna lies in its good directed pattern. In order to better play its excellent properties, many scholars has carried out the comprehensive and in-depth research and analysis. So the ring slot antenna in the present and in the future research or application has a broad development space[6]. Figure 1 depicts the geometry which is digged a circular groove and the coordinate system in an ideal conductive plate. The magnetic fluid distribution equivalent circuit diagram is shown in figure 1:

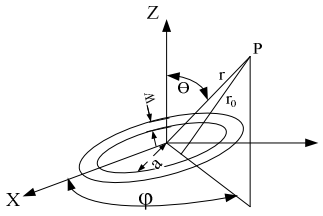

Fig1 Annular gap and coordinate system

$$\bar{M}(\rho,\varphi') = \bar{E}_a(\rho,\varphi') \times \hat{n} \tag{1}$$

The mouth surface electric field in formula(1) is shown by $\bar{E}_a$; the unit vector $\hat{n}$ is perpendicular to the mouth. Electric vector formula (2) ought to be used in calculating the far field radiation pattern of the ring slot antenna .

$$\bar{H}(r) = -j\omega\bar{F}, \bar{E}(r) = \eta_0\bar{H}(r) \tag{2}$$

Distant district Θ and φ of radiation electric field component needs to plug in the corresponding electric vector for calculation:

$$E_\theta = \frac{-jk_0}{4\pi}\frac{e^{-jk_0r}}{r}\int_0^{2\pi}\int_a^{a+W_s}\{M(\rho)\sin(\varphi'-\varphi) - M(\varphi')\cos(\varphi'-\varphi)\}\cdot$$
$$e^{-j\rho k_0\sin\theta\cos(\varphi'-\varphi)}\rho d\rho d\varphi'$$
$$E_\varphi = \frac{jk_0}{4\pi}\frac{e^{-jk_0r}}{r}\cos\theta\int_0^{2\pi}\int_a^{a+W_s}\{M(\rho)\cos(\varphi'-\varphi) - M(\varphi')\sin(\varphi'-\varphi)\}\cdot$$
$$e^{-j\rho k_0\sin\theta\cos(\varphi'-\varphi)}\rho d\rho d\varphi'$$

Besides the annular gap in radius is "a",and

$$\bar{M}(\rho,\varphi') = M(\rho)\hat{\rho} + M(\varphi')\hat{\varphi}' = -E_{\varphi'}\hat{\rho} + E_\rho\hat{\varphi}'$$

the Ws is far less than λ_0 ,and $E_{\varphi'} = 0$, $E_\rho = E_0$ is a constant.

$$E_\theta = \frac{-jk_0W_s}{4\pi}\frac{E_0ae^{-jk_0r}}{r}\int_0^{2\pi}\cos(\varphi'-\varphi)e^{jak_0\sin\theta\cos(\varphi'-\varphi)}d\varphi'$$
$$E_\varphi = \frac{-jk_0W_s}{4\pi}\frac{E_0ae^{-jk_0r}}{r}\cos\theta\int_0^{2\pi}\sin(\varphi'-\varphi)e^{jak_0\sin\theta\cos(\varphi'-\varphi)}d\varphi'$$

Integral φ' can be launched

$$E_\theta = \frac{k_0W_s}{2}\frac{E_0ae^{-jk_0r}}{r}J_1(ak_0\sin\theta),\ E_\varphi = 0,\ E_\theta = \frac{-jk_0W_s}{4\pi}\frac{E_0ae^{-jk_0r}}{r}\int_0^{2\pi}\cos n\varphi'\cos(\varphi'-\varphi)e^{jak_0\sin\theta\cos(\varphi'-\varphi)}d\varphi'$$
$$E_\varphi = \frac{-jk_0W_s}{4\pi}\frac{E_0ae^{-jk_0r}}{r}\cos\theta\int_0^{2\pi}\cos n\varphi'\sin(\varphi'-\varphi)e^{jak_0\sin\theta\cos(\varphi'-\varphi)}d\varphi'$$

Integral φ' can also be launched

$$E_\theta = \frac{-j^nk_0E_0aW_s}{2}\frac{e^{-jk_0r}}{r}\cos n\varphi J_n'(ak_0\sin\theta)\quad E_\varphi = \frac{j^nnE_0W_s}{2}\frac{e^{-jk_0r}}{r}\sin n\varphi\cot\theta J_n(ak_0\sin\theta)$$

Because the annular slot antenna can produce linear polarization field, and other methods of radiation characteristics and application of microstrip antenna are essentially the same,we can make sure according to the formula of field.

B .Antenna structure. Ring slot antenna is a circular aperture slot digged on the floor of the antenna dielectric substrate without any doubt[7].As is shown in Fig 2 a, A_5 is a good conductive plane. Make inward a rectangular cavity with a side length of D * D, height of H, and material being qualitative with good conductors. Open a circular radiating slot A_1 whose width is S on the A_5, and use the inner conductor column A_4 of the coaxial line to connect A_5 and the conductor cavity and feed the antenna. There are two impedance matching metal rings A_2 and A_3 in the conductor cavity. When the antenna loaded on the helicopter, you can put a layer of non-conductive material on the surface of the antenna to make the surface of the helicopter more smooth.

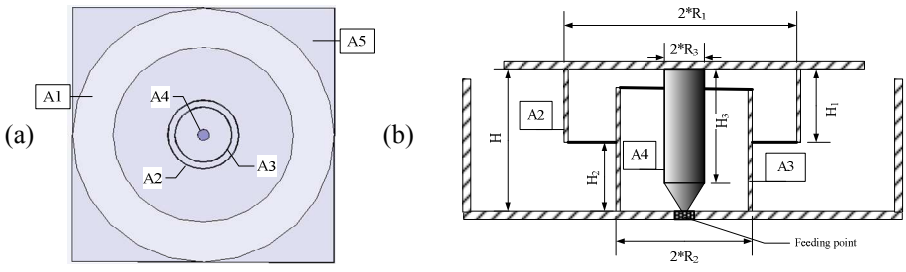

Fig 2 The structure diagram of annular slot antenna.(a) Antenna top view. (b) Antenna section

From fig 2 b antenna section to be seen, the inner conductor A_4 is kind of vertebral body which is connected by two halves .The first half is a cylindrical conductor and the second half is a vertebral body with radius of diminishing. The end of the conductor is connected to the feed point.In order to match impedance with conductor column A_4,we load a metal ring A_2 and A_3 on the surface of the metal cavity up and down respectively. As is shown in fig 2 b, the height of the outer ring A_2 is H_1,and the radius is R_1.The height of the inner ring A_3 is H_2 ,and the radius is R_2.The cone height of the inner conductor A_4 is H_3,and the radius is R_3.

Results and Analysis

A.The Antenna Performance. According to the simulation optimization of the HFSS Ansoft, the specific body size of the antenna can be determined in the following table:

Table 1 Structure size parameters of the ring slot antenna(unit: mm)

Part name	The numerical	Part name	The numerical
Slot depth (H)	80	Slot width (D)	500
The metal ring height (H1, H2)	79	Metal ring radius of A2 (R1)	118
Annular gap width (N)	50	Metal ring radius of A3 (R2)	40
Conductive cylinder height (H3)	68	Conductive cylinder radius (R3)	9

B .The Antenna Bandwidth.

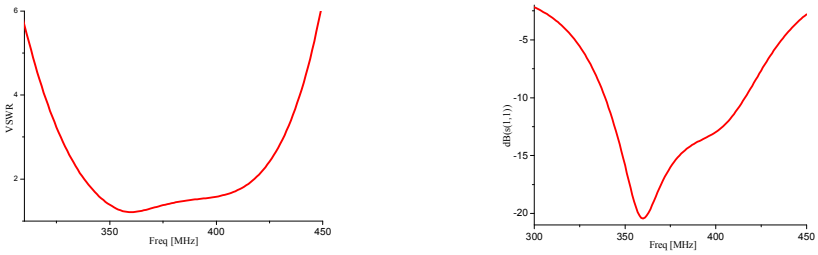

Fig 3 Standing wave and return loss of annular slot antenna

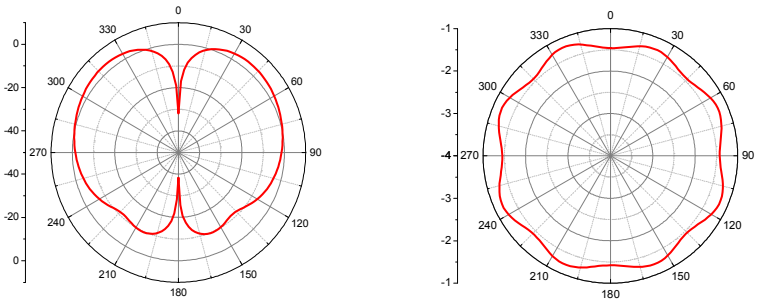
As the Fig 3 shown, on the 300MHz to 450MHz band, the band width of antenna pattern which meets VSWR<2 is 338MHz～438MHz and relative bandwidth is 22.22%. When the band width is 350MHz～376MHz,its VSWR<1.4 which achieves 26MHz completely covering the relevant ultra short wave communication frequency band.In the 350MHz, VSWR is 1.384 and S_{11} is -15.859dB. In the 370MHz, VSWR is 1.309 and S11 is -17.462dB. In the 350MHz to 370MHz frequency range, S11 is less than -14.6dB. They meet the requirements of the relevant communication equipment to the antenna.

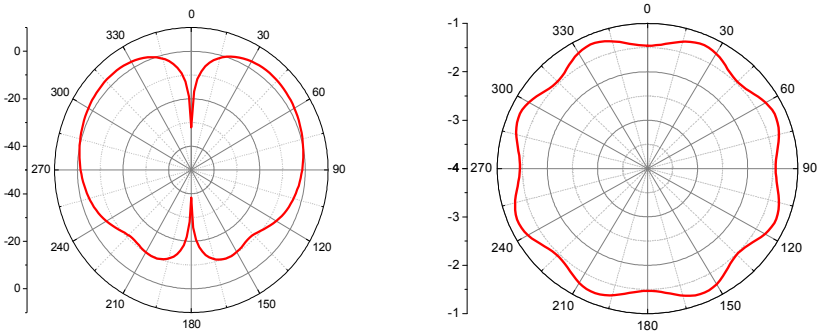
C.Radiation Characteristics

By observation of Fig 4a) and Fig 5a), antenna pattern can get the biggest gain in the θ value around 45° and 315°. Due to the reflection of electromagnetic wave, between the θ value of 90° and 180°, radiation intensity has the phenomenon of attenuation. According to the requirements of practical application of airborne antenna, the basic characteristics of the antenna's radiation conform to the requirements of the airborne antenna radiation.



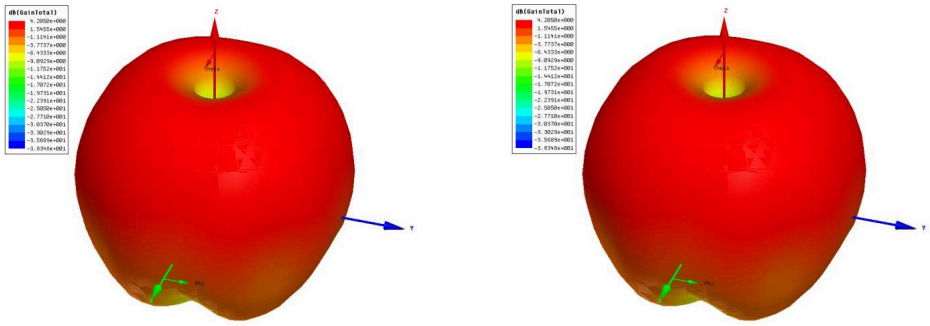
a) x-z plane b) x-y plane

Fig 4 Annular slot antenna pattern at 350MHz



a) x-z plane b) x-y plane

Fig 5 Annular slot antenna pattern at 370MHz



(a)350MHz Gain pattern (b)370MHz Gain pattern

Fig 6 Gain pattern of annular slot antenna

Conclusion

Based on the slot antenna as the breakthrough point, combined with relevant station technical index requirements of communication antenna, the paper designs out the annular slot antenna. The antenna can be well with the aircraft carrier conformal, to achieve reducing resistance and hiding antenna itself. The antenna pattern meet VSWR<2 and relative bandwidth is 22.22%. Within the working frequency band, antenna standing wave is greater than 3dB. Through careful simulation to compare the circular seam width with radius and height when impedance matching metal ring, the optimal size values can be determined. The antenna pattern simulation results meet that when the VSWR<1.4, the band width is 350MHz～376MHz; when the VSWR<2, the band width is 338MHz～438MHz and the biggest gain in the operating frequency range is 4.205dB. It successfully meets the design requirements for miniaturization and conformal of the airborne antenna.

Based on small current grounding fault analysis and testing

Huailian lv

Yantai Engineering & Technology College, Yantai, China

lhl1313@163.com

Keywords: Small Current Grounding Fault; FTU; Zero Sequence Current

Abstract. distribution network line usually adopt neutral point grounding way of three-phase three-wire power supply, improve the power supply reliability, reduce the line loss, increase the margin level of the distribution line, reduce the rate of tripping. But using three-phase three-wire power supply line in the actual operation of distribution network, the single-phase earth fault happens often, seriously affected the substation equipment and the safe and economic operation of the distribution network. Based on such fault is analyzed, and puts forward new on feeder terminal for such fault detection scheme.

Introduction

Distribution network medium and small current grounding generally refers to 10 kv and 6 kv single-phase grounding happening somewhere on the feeder. A neutral point is usually not grounded in our distribution network system, and basic for three-phase three-wire system running(the main transformer connection group to Y/Δ,Y/Y0 for distribution transformer connection group), Although certain changes in single-phase grounding running characteristics, but quite a small fault current value(Less than the normal load current) Damage is not obvious. But if long time grounding, grounding phase voltage will be reduced, the grounding phase voltage to rise to the line voltage, pose a threat to electric equipment insulation. Single-phase earth fault occurs after the system can't run for a long time. Therefore, the operational procedures of distribution network in China make clear a regulation, when the single-phase grounding distribution network system is allowed to run for two hours. This period of time can be used to find out the cause of the problem and troubleshooting.

The small current grounding fault analysis

Now the brief analysis of operational characteristics of the small current grounding as follows. In figure 1 as an example, the normal load can ignore its load characteristic constant impedance model instead of:

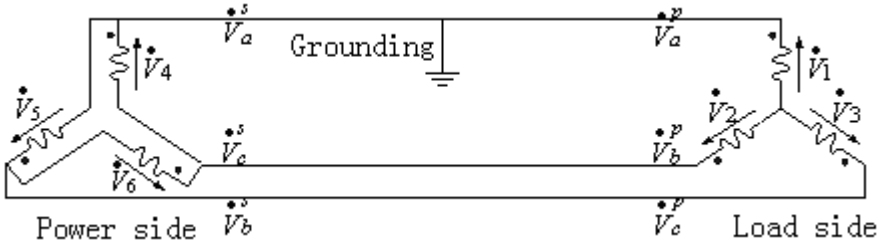

Fig. 1. No earth neutral system occur ground fault

Power supply side of main transformer secondary side for Δ connection form; Lateral load equivalent to a constant impedance, expressed as a Y wiring (wiring can also, analyze the conclusion). First assumed load asymmetric three-phase equilibrium and ignore electrical equipment parameters, when the normal operation of the voltage vector is symmetrical, as shown in figure 2:

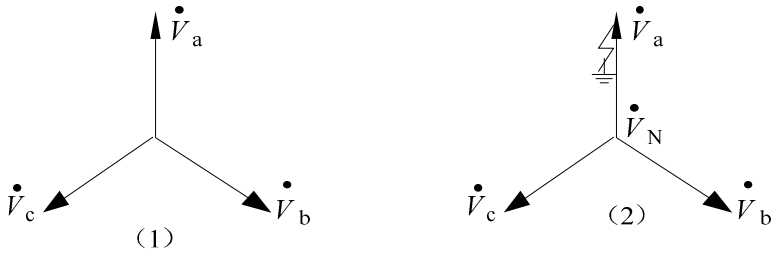

Fig. 2. Current ground fault phasor diagram

The line voltage vector $\dot{U}_{ab}$, $\dot{U}_{bc}$ and $\dot{U}_{ca}$ Is completely symmetrical，the neutral point voltage is only 0.

1. Ignore the line charging capacitance, assume that a phase of single-phase grounding, a phase voltage is equal to the voltage (zero value), the figure 2: the neutral point voltage is zero, no longer a phase voltage rise but negative; But no matter how the neutral point voltage changes, because is not grounded system, there is no zero sequence circuit, line voltage is kept constant, the line voltage vector, and still completely symmetrical. Therefore, at this time of single-phase grounding had no effect on the normal operation of the system.

2. Meter and the line charging capacitance, the capacitance through the ground to form current loop. But as a result of general distribution circuit charging capacitance is very small (especially the overhead line), the capacitance current is small on numerical (below 10 ~ 20), is far less than the normal load current (200 ~ 300). At this time of the line voltage vector due to the existence of the capacitive current and slightly affected, but basically is still in a symmetrical running state.

3. Considering the influence of the distribution of three-phase load characteristics. 400 v power distribution lines except some straight for industrial lines generally USES three phase four wire system running, three-phase load under normal circumstances there is asymmetry. This asymmetry makes the load current flows through a certain value in the neutral line, resulting in three phase line voltage to produce a certain degree of asymmetry. The line voltage due to asymmetric load asymmetric effect than effect of capacitive current lead to often, so the asymmetric characteristics caused by single-phase grounding is likely to have been load off the asymmetry of oblivion, is difficult to distinguish whether there is a single phase grounding.

4. Current transformer in our country mostly adopts the standard model, 500/5, 600/5, and so on. Because of the single phase grounding capacitive current is quite small, line current value is basically a superimposed on the load current is relatively small current, this small change in the CT secondary side is basically not to come out. In addition, if consider adopting zero sequence current transformer is measured, tend to see the asymmetry of current when single-phase grounding than the normal run time asymmetry caused by the asymmetric load current is small, so it is difficult to tell whether there is a single phase grounding.

5. 35 kv neutral point is usually used in distribution system via arc suppression coil grounding, although the capacitive current is 10 kv line is big, but due to the effect of compensation of the arc suppression coil largely offset the impact of capacitive current, show the running characteristics of basically similar to 10 kv system.

Based on the analysis, the small current grounding had little effect on characteristics of three-phase power distribution system, the conventional fault detection method is difficult to accurately locate the fault point, is one of the difficult problem of the current international.

FTU for small current grounding fault detection scheme

For such failure, we more reliable detection scheme is obtained through practice. Through acquisition of zero sequence current value and the event of a failure experience of zero sequence values compared to determine the small current grounding fault. Is the key technology of how to gather the zero sequence current. Here is to collect the zero sequence current based on our practice and figure out a practical method.

Used to measure the zero sequence current is used 100/1 of the special current transformer (figure 3), because of the zero sequence current transformer using plugin installation caused the inconvenience of use, then changed to remove the zero sequence current transformer, directly in the FTU collected by means of modified wiring zero sequence current. Now use scheme, switch the original A, B, C three-phase CT B phase CT is short of, the zero sequence CT secondary outlet connected to the original used to pick up the position of the B phase CT secondary outlet, so mining by FTU B phase current is, in fact, zero sequence current. Wiring principle as shown in figure 3:

After transforming: still use FTU B phase CT to measuring the zero sequence current, principle as shown in figure 4:

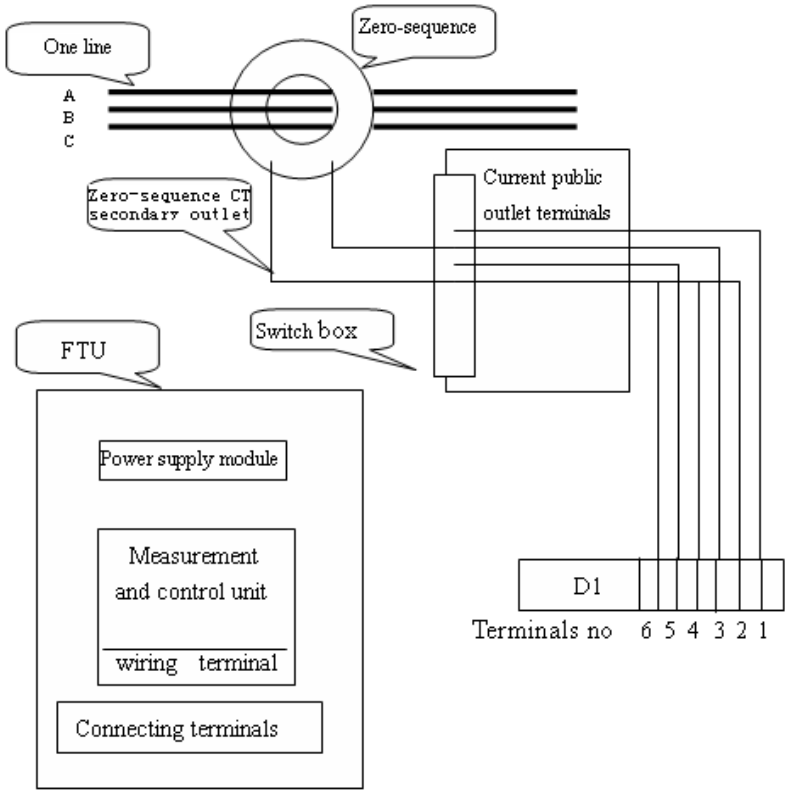

Fig. 3. Wiring diagram zero-sequence current ground fault

The switch side: From two lines of the zero sequence CT secondary side and from the terminal to connect the two wires short, the original short meet together from B phase CT secondary side of the two wires connected to the two vacant terminal.

FTU side: the original in the FTU terminals on the terminal 2 and 6 of D1 line connected to terminal 4, with two short wires respectively 2— 3, 3—6 short answer.

Such three phase current through the FTU B phase CT outflow, so at this time of FTU B phase CT measured is actually zero sequence current.

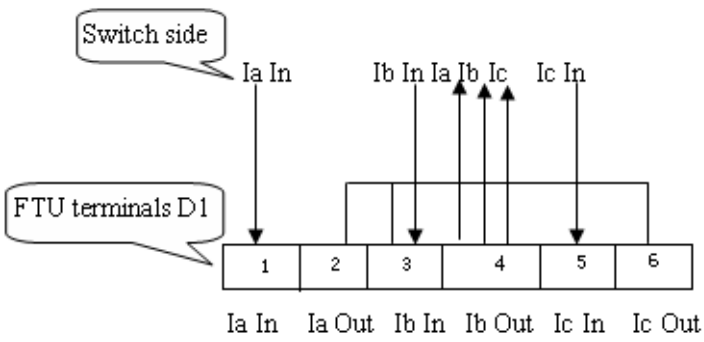

Fig. 4. Wiring diagram zero-sequence current changed ground fault

Conclusion

In this article, through the analysis of the small current grounding fault, put forward a good detection scheme, the fault in the actual played an important role in the operation of the system, save a lot of manpower and material resources, greater economic and social benefits were obtained.

Keywords: Artificial neural network, Genetic algorithm, Blast furnace, Hot metal, Silicon content

Abstract. In this paper, a predicting model of silicon content in blast furnace hot metal is built based on artificial neural network and genetic algorithm, which optimizes the initialization weight values of neural network with genetic algorithm. This model can effectively improve the prediction accuracy and reduce the calculating time. Online application shows that the predicting model can effectively predict the silicon content in blast furnace hot metal and play an important role in production. when required absolute error was within ±0.03, the accuracy of model can reach 81.4%, and when absolute error was within ±0.04, the accuracy can reach 91.4%.

Introduction

Silicon content is an important index to describe hot metal quality, and silicon in blast furnace comes from the reduction of raw materials[1].

In actual production, there are many factors affect the silicon content in hot metal, such as coal rate, coke rate, air pressure, top pressure, iron ore grade and so on. As the complexity of the reactions in blast furnace, the factors involves many aspects in blast furnace, and the relationship between the silicon content in hot metal and the affect factors is not a linear, so traditional model is difficult to accurately predict the silicon content in hot metal.

The development of artificial neural network has provided conditions to solving such nonlinear problems[2,3]. So some researchers established artificial neural network prediction model to predict the silicon content in hot metal[4]. But neural network have some disadvantages, the prediction accuracy is not very ideal. Genetic algorithm has very powerful search capabilities. Combining neural network and genetic algorithm to search optimization is a new trend of numerical simulation[5,6]. In this paper, a predicting model of silicon content in hot metal is built based on artificial neural network and genetic algorithm, which optimizes the initialization weight values of neural network with genetic algorithm. This model aims to improve the prediction accuracy and reduce the calculating time.

Artificial Neural Network and Genetic Algorithm

Artificial Neural Network. Artificial Neural Network (short for ANN) is a nonlinear, adaptive, self-organizing system that composed of a large number of simple processing units, which is based on modern neuroscience research, trying to simulate the human nervous system to perform information processing, memory and processing methods, and designed an information processing system as human brain style. Artificial neural network has lots of characteristics, such as distributed memory, parallel processing, fault-tolerant ability, any complex nonlinear systems, self-learning, adaptive ability and so on, it has a unique advantage on resolving the production process problems with many parameters and inconspicuous regularity. In the artificial neural network algorithm, BP algorithm (error back propagation algorithm) is the most widely used training algorithm for multi-level network. BP neural network is compose of input layer, hidden layer and output layer.

Genetic Algorithm. Genetic algorithm (short for GA) is an adaptive heuristic global search algorithm based on natural selection and population genetics mechanism, which proposed by Professor J. H. Holland from the University of Michigan in early 1960's, and described in "natural and artificial adaptive system" published in 1975. Genetic algorithms start as a group of randomly generated candidate solutions (each solution are expressed as a string), through the use of genetic operators to combine these strings, so that these candidate solutions gradually evolve toward the direction of the optimal solution. These genetic operators (including the choice of reproduction, crossover and mutation) are simulation of natural reproduction, crossover and mutation phenomenon that occurred in natural selection and genetic processes. For a given problem, the group of P(t) that maintains a constant number of each generation is evaluated by calculating fitness value F (that the ability to adapt to the environment) of each individual in the group. The copy opportunities of individual are distributed according to the fitness value, and the individuals with high fitness value get more chance to reproduce in the next generation and produce more offspring, while individuals with low fitness value produced less offspring and even replaced by some better offspring. The selected individuals carry crossover and mutation operation through crossover probability Pc and mutation probability Pm to produce a new generation. The search ability of genetic algorithm is mainly given by the replication and cross, while the mutation operator guarantees the ability of searching every points of the solution space, which makes it has a global convergence.

Combination of genetic algorithms and BP neural network. Neural networks and genetic algorithms are theories imitating biological treatment mode to get intelligent information processing. Neural networks focuses on the brain's neural network micro-structure, through complicated connection of a large number of neurons, and using the method from the bottom to the top, though the parallel distributed arithmetic formed from self-learning, self-organizations and non-linear dynamics to deal with pattern information which is difficult to be verbalized, and it has a strong self-learning and associative memory function. Genetic algorithm is a search method depending on the simulation of the biological evolution phenomenon (natural selection, crossover and mutation, etc.), and using natural evolution mechanism to represent a complex phenomenon, with the purpose of solving various difficult problems effectively, which has irreplaceable advantages in the global search and self-adaptation.

From the own characteristics of BP algorithm neural networks and genetic algorithms, BP algorithm training is based on the weight modification principle of the error gradient descent, which inevitably exists the problem that falling into the local minima. Genetic algorithms are good at global searching, but lack of capacity for the exactly local search. The combination of genetic algorithms and BP algorithm achieves the mutual advantages result, to the benefit of better solving the problem of blast parameters prediction.

Though the genetic algorithm optimizes initial weights of BP neural network can make a wide range of values, and also introduce the information of peak error modification into initial weights, which improves the peak mapping accuracy. The flow chart of the model that genetic algorithm optimizes initial weights of BP neural network is shown in Figure 1.

Model Calculations

Model structure. (1) Input layer. In this model, based on the correlation of actual production conditions and the silicon content in hot metal, selected 11 closely related with the hot metal silicon content parameters as input variables, such as coal ratio, coke ratio, air pressure, top pressure, sulfur load, iron ore grade, blast capacity, air temperature, ventilating index, slag basicity and Si content. (2) Hidden layer. In this study, hidden layer is one layer. The number of hidden neurons expresses the nonlinearity degree of the input and output in the network, which has an important impact on the network model training speed and forecasting capabilities. Based on a large number of calculation tests, select the number of hidden layer neurons is 14. (3) Output layer. The number of neurons in the output layer depends on the system requirements of network function, in order to achieve the

prediction of silicon content in hot metal; the output variable in this model is the silicon content in hot metal, so the number of neurons in output layer is 1.

Samples normalized processing. Because of the different input variables units and the difference of absolute value, in order to avoid the influence of neural network model, the normalized processing of input parameters and output parameters is necessary. In this model, BP network uses Sigmoid function as the excitation function, requiring the input and the output value of each node should be in [0,1]. Therefore, the parameter values needed to be converted in [0, 1], the input layer parameter values use the following linear conversion:

$$x(p,i) = \frac{x_{act}(p,i) - x_{min}(i) \times 0.9}{x_{max}(p,i) \times 1.1 - x_{min}(i) \times 0.9}$$

Where: $x\ (p,\ i)$ - sample values of parameters in the sample; $x_{act}\ (p,\ i)$ - the actual value of parameters in the sample; $x_{min}\ (i)$ - the minimum sample set parameters; $x_{max}\ (i)$ - and maximum sample set parameters.

Selection of the main operational parameters. The main parameters in the calculation are: (1) Genetic algorithms: population size is 20, selection probability is 0.08, the crossover probability is 0.1, mutation probability is 0.055, the initial weight value space is [- 5,5], evolution generation is 200. (2) BP neural network: momentum coefficient is 0.7, learning rate is 0.9, excitation function is S-type function, and system error is 0.0022.

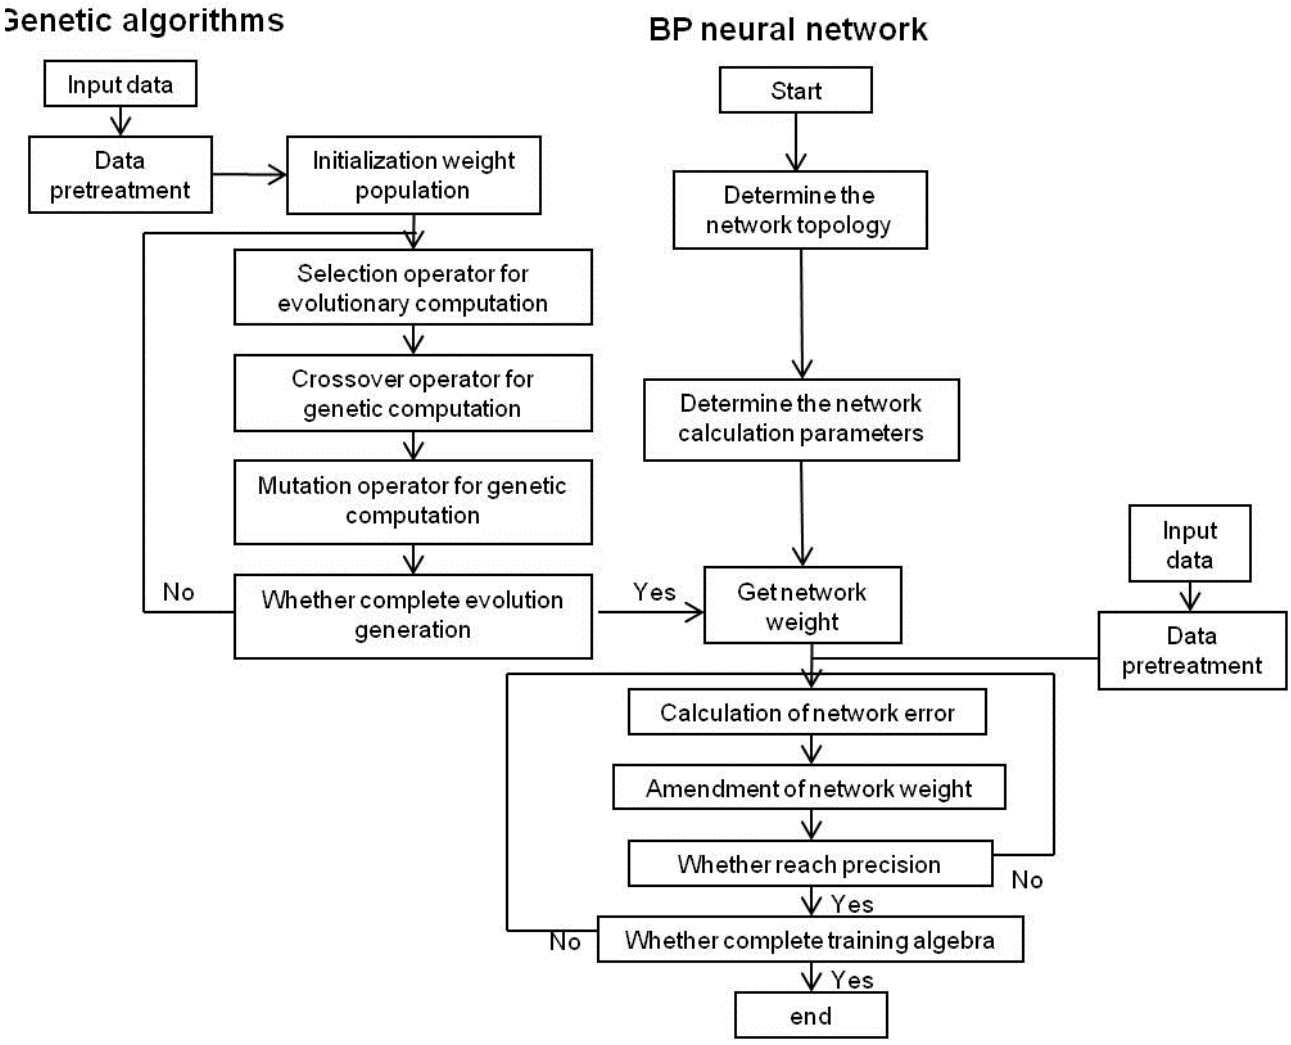

Fig. 3. Flow chart of genetic algorithm optimizes BP neural network initial weights model

Comparison of Calculation and Application

A 220 h continuous production data (220 groups) was used in calculation, including 150 sets of data used for training the network, another 70 sets of data for off-line prediction. First, the silicon content in hot metal was predicted by a neural network model. On this basis, adding genetic algorithm to optimize the model of neural network initial weights. The calculation training times of the former was 20,000, and the latter's training times was 10,000. The comparison of off-line prediction results of the two calculation methods were shown in Table 1. The comparison between the actual values and model calculation value after adding the genetic algorithm were shown in Figure 4.

Table 1. The comparation of calculation result of the two method

Error range/%	Neural network		Genetic network optimizes neural network	
	Hit sample number	Hit rate/%	Hit sample number	Hit rate/%
<0.03	55	78.6	57	81.4
<0.04	62	88.6	64	91.4
<0.05	65	92.9	67	95.7

From Table 1, it can be seen that the prediction precision of the combination model of genetic algorithm and BP neural network was superior to BP neural network prediction model. And the number of training times was reduced effectively.

Based on the modified prediction ideas, an online prediction function was designed to test silicon content in hot metal. With the blast furnace production running, the required real-time production data of each hour was imported into the system and the model did training again. At the same time, the first set of data in the group of samples was out according to the FIFO principle. Thus, with the production running, the network was learned and corrected momentarily, the model will adapt to the new production conditions better, so does the forecast results. Currently, the model has been tested and applied in actual production. Application results show the model was stable and reliable; and the hit rate of the model was higher. It provides a good guidance for the actual production of blast furnace.

Conclusion

This paper uses two methods of BP neural network, genetic algorithm and BP neural networks combination to establish a prediction model of hot metal silicon content. Two kinds of model were trained by 150 sets of data and finished off-line prediction through 70 sets of data. Prediction results indicate that the combinative model of genetic algorithm and BP neural network is better than BP neural network model in the aspects of precision rate and training times. Online application shows that the model can predict the silicon content in hot metal effectively; it plays a well directive role in the actual production of blast furnace.

Keywords: Aluminum nitride, Debye temperature, Thermal conductivity, Heat capacity

Abstract. Thermal conductivity of aluminum nitride (AlN) has been calculated by density functional perturbation theory (DFPT) and quasi-harmonic approximation (QHA) combined with Debye theory in the paper. Debye temperature is evaluated respectively from sound velocity and heat capacity. From 300K up to 1000K, the predicted thermal properties in pure crystal AlN based on these two Debye temperatures are compared with each other and the latter shows excellent agreement with Slack's experimental data. The relative difference based on Debye temperature from heat capacity is within the limits of ±5.5%. This agreement with experiment is due to the Debye temperature derived from capacity contains the temperature effect while describe the three phonon process.

Introduction

The thermal conductivity of materials is very important in a great variety of device applications where heat flow plays a role such as thermoelectric energy conversion, memories, or heat sinks [1-2]. AlN is an attractive substrate material for these applications due to its high thermal conductivity, low expansion coefficient, low dielectric constant and high electrical resistivity, as well as the good compatibility with complementary metal-oxide semiconductor technology [3]. In the case of high power light emitting diodes (LEDs), the heat dispersion has significant influence on its optical properties One of the effective thermal solutions for high power LEDs is using high conductivity AlN as heat sinks.

Thermal properties are determined by the diffusion of phonons through the solid in the case of AlN. In this paper, thermal conductivity of phonons in pure crystal AlN has been theoretically studied using the functional perturbation theory and quasi-harmonic approximation combined with Debye theory. Thermal conductivity is considered from temperature 300K up to 1000K. Two Debye temperatures evaluated respectively from sound velocity and heat capacity are used in the model. The results are compared with experimental data and good agreements in the latter one are achieved.

Theoretical Method

Heat transport is due to the energy excitations which are mobile, principally electrons and phonons. As the electronic thermal conductivity in insulators can be neglected, the total thermal conductivity is dominated by phonons, which can be calculated by using the standard Debye expression:

$$\lambda(T) = \frac{1}{3}\int_0^{\omega_D} v_m C_v(\omega,T) l(\omega,T) d\omega \tag{1}$$

In this model, the average sound velocity v_m of the material is a constant number and is assumed to be independent of the modes and wave vectors, thus can be taken out of the integral. $C_v(\omega,T)$ is the specific heat capacity at constant volume, ω_D is the Debye frequency, $l(\omega,T)$ the total phonon mean free path at different frequencies and temperatures. These parameters will be computed using the density functional perturbation theory, combined with quasi-harmonic approximation later.

The average sound velocity v_m is determined by the longitudinal wave speeds v_l and transverse wave speeds v_t:

$$v_m = [\frac{1}{3}(\frac{2}{v_t^3} + \frac{1}{v_l^3})]^{-\frac{1}{3}} \tag{2}$$

The relation of Debye temperature θ_D and average sound velocity v_m is:

$$\theta_D = \frac{\hbar}{K_B}(6\pi^2 \frac{N}{V})^{\frac{1}{3}} v_m \tag{3}$$

where N is the number of atoms in the unit cell, V is the cell volume. K_B is Boltzmann's constant and $\hbar$ Planck's constant.

The dependence of the frequency on the wave vector can be calculated through Hessian matrix. The Hessian matrix is:

$$D_{\mu\nu}(R - R') = \frac{\partial^2 E}{\partial u_\mu(R)\partial u_\nu(R)}\Big|_{u=0} \tag{4}$$

Here u refers to the displacement of a given atom and E is the total energy in the harmonic approximation. Phonon density of states (DOS) can be achieved from the phonon spectra.

The value of the Debye temperature at a given temperature can also be obtained by calculating the actual specific heat capacity at constant volume (Eq.6) and then inverting the Debye specific heat capacity (Eq.5) to obtain Θ_D.

$$c_v^D(T) = 9NK_B(\frac{T}{\theta_D})^3 \int_0^{\frac{\theta_D}{T}} \frac{x^4 e^x}{(e^x - 1)^2} dx \tag{5}$$

$$c_v(T) = K_B \int \frac{x^2 e^x}{(e^x - 1)^2} F(\omega) d(\omega) \tag{6}$$

where x is $\hbar\omega/K_BT$ and $F(\omega)$ is the phonon density of states. The DFPT is employed to determine the phonon density of states by using the norm-conserving pseudo-potential method. Based on the QHA theory, the actual heat capacity of AlN is calculated using the phonon density of states.

Results and Discussion

Before computation, the structure of wurtzite AlN is geometrically optimized. The experimental velocities of the longitudinal wave vl, transverse wave vt and the calculated average sound velocity vm are shown in Table 1. Debye temperature predicted from Eq.3 is also given in Table 1. The computed values are all in good agreement with experimental data.

Table 1 Sound velocities and Debye temperature in wurtzite AlN

Method	v_l [m·s^{-1}]	v_t [m·s^{-1}]	v_m [m·s^{-1}]	Θ_{DS} [K]
This work			6975.9	967.7
Experiments	10127*	6333*	6980**	950***

*Ref. [4] ** Ref. [5] *** Ref. [6]

The computed phonon DOS of wurtzite AlN is provided in Fig.1. A strong peak value about 0.42 of the optical phonon modes in the DOS appears at 19.97THz in this structure. The cut-off frequency of acoustical phonon modes is 17.72THz.

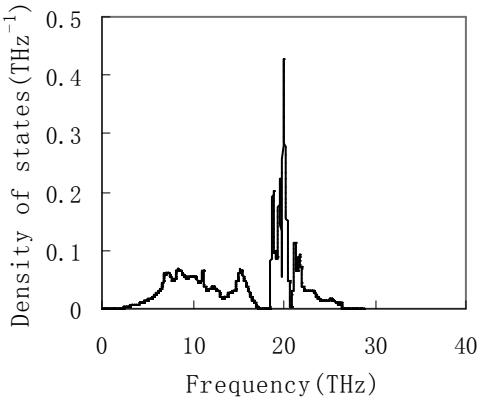

Fig.1 Phonon DOS in wurtzite AlN

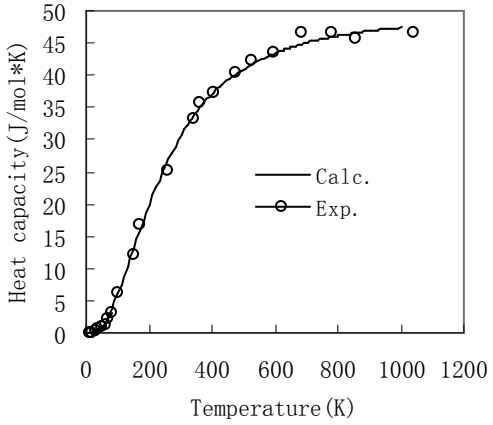

Fig.2 Heat capacity in wurtzite AlN

Fig.2 shows the calculated heat capacity and experimental values reported by Koshchenko et al [7]. The agreement is excellent below 600K, which shows the quasi-harmonic approximation gives correct results in this temperature region. The difference for higher temperature comes from the fact that the an-harmonic effects, which become important for high temperature, are not considered in the calculations. At high temperature，the specific heat capacity approaches to the Petit-Dulong limit. At low temperature, the heat capacity depends only on the characters of the long acoustic wave and the value is small.

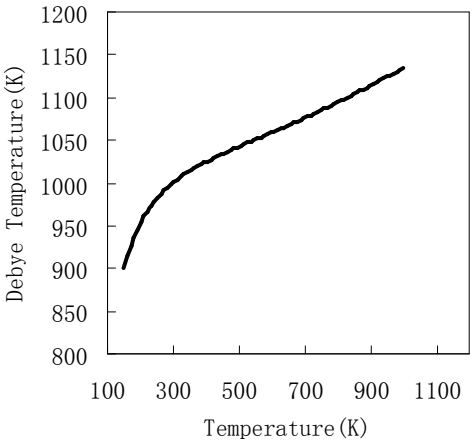

Fig.3 Debye temperature in wurtzite AlN

Debye temperature is not only related to sound velocity, but also to the specific heat capacity. Based on the calculated heat capacity, the Debye temperature can be predicted. The obtained Debye temperatures Θ_{DH} at various temperatures are shown in Fig.3. The Debye temperature increases more quickly at low temperature than that at high temperature.

Table 2 Theoretical and experimental thermal conductivity of pure wurtzite AlN

Temperature[K]	*300*	*350*	*400*	*500*	*600*	**1000**
λ from experiments* [W/m•K]	319	253	195	137	100	49
λ_{DH} from Θ_{DH} [W/m•K]	301.7	248.5	204.4	142.8	105.5	47.7
Δ_{DH} [%]	-5.4	-1.9	4.8	3.9	5.5	-2.6
λ_{DS} from Θ_{DS} [W/m•K]	355.3	297.4	251.3	180.5	137.2	70.8
Δ_{DS} [%]	11.4	17.5	28.8	31.7	37.2	44.4

* Ref. [6]

Table 2 shows the thermal conductivity λ of pure wurtzite AlN single crystal calculated from Eq.1. The Debye temperatures Θ_{DS} and Θ_{DH} used in the integration are derived from sound velocity and heat capacity respectively. The values from experiments are also shown in Table 2. The thermal conductivity computed from Θ_{DH} agrees better with the experimental data than that from Θ_{DS}. The calculated relative difference Δ_{DH} is within the limits of ±5.5%. As it was pointed out in Ref. [8] that the measurement error was ±10% beyond 300K, our theoretical results based on Θ_{DH} can be regarded as reliable. In the intermediate and high-temperature ranges, the intrinsic thermal conductivity of the sample is dominated by three-phonon scattering processes. The good agreement of theoretical values with experiments shows that the model we used describes the three-phonon scattering process correctly. The Debye temperature derived from capacity can describe the process more accurately because it contains the temperature effect.

Conclusion

Thermal conductivity of AlN has been theoretically studied in this paper based on density functional perturbation theory (DFPT) and quasi-harmonic approximation (QHA) theory combined with Debye theory. From 300K up to 1000K, thermal conductivities of pure crystal AlN are calculated respectively from Debye temperature evaluated from sound velocity and heat capacity. The comparison with Slack's results shows that Debye temperature evaluated from heat capacity gives a more reasonable thermal conductivity. These agreements suggest that the theoretical method we used in our study is an effective approach to calculate the thermal conductivity in pure crystal AlN. The one short coming of the methodology in this paper is that the grain sizes, the defects and the thickness of grain boundaries and Al vacancies generated by oxygen content in AlN are not taken into account.

Keywords: food thawing; numerical simulation; cylindrical food; thawing time

Abstract. It is very meaningful to predict the temperature and thawing time during the thawing process of frozen food in production and life, this paper proposes a physical model of cylindrical frozen food during the thawing process, combine the finite difference method with element balance method to solve the thawing time and the temperature at regional center R/2 and boundary nodes. Take the beef as an example for the experimental verification. Through numerical calculation and experimental verification, the maximum error between the theory thawing time and experiment is 8.4%. The results show that: it is highly consistent with the experimental results that using numerical method to predict the thawing time and temperature change curve, at the same time, the temperature maximum error in center area is 1.2℃, the temperature maximum error of R/2 is 0.8℃, the temperature maximum error of the boundary node is 1.5℃, so the numerical simulation in studying thawing of freezing food is fairly reliable.

Introduction

Frozen food industry is one of the fastest growing food industries in the world, the development is also very rapid in China. In the first half of 2013, our country's frozen food trade volume trend is rising, the value of import and export is $13,290,000,000, it rose by 14.3% to over the previous year. At the same time, people have been concerned about the food freezing and thawing theory, because it is directly related to food safety and quality problems. Theoretically, thawing is the inverse process of freezing; they are different not only in phase change direction, cooling and heating process, but also in food freezing time and internal temperature variations [1]. The thawing process is to make the freezing ice melts into water inside the food, and absorbed by the food then restored to the fresh state before frozen. The degree of cells in the thawing recovery determines the thawing quality of frozen products [2]. Therefore the thawing process is much more complex than the freezing process.

Requirements in the process of thawing meat [3]: a. Homogeneous half thawed state is the best; b. The outflow of meat tissue in the thawing process to the less as far as possible; c. Inhibit the reproduction and generation of microorganisms; d. Thawing medium temperature is low, less than 20℃; e. The temperature can't be too high during the thawing process in order to avoid the destruction of tissue structure; f. Thawing as quickly as possible, so as to shorten the time when food stays in the higher temperature. Frozen vegetables, bread, pastries and so on are suitable for quick thawing; but to fish and meat, using slow thawing the effect is better [4].

This paper studies the thawing time of cylindrical food, taking frozen beef roll with a radius of R=32mm as the object of study. In order to research conveniently in the process of solving, putting forward several assumptions for the object of study and the environment: The thermal conductivity coefficient and specific heat of beef is only relevant to temperature ignoring other factors; Beef density is constant; deeming the surrounding environment is infinite space, so the temperature of the surrounding medium does not change with time; Considering the beef roll in the thawing process is big length to diameter ratio, so in the thawing process heat transfer occurs mainly in the

radial direction, while the heat transfer along the axial direction is weak and negligible, namely heat transfer is one-dimensional heat conduction; temperature field distribution is uniform.

Removed beef roll from the freezer, measured the initial temperature is -20℃, and the thawing end temperature requires that center temperature achieves 0.5℃, do research and experiment on the premise of the temperature.

Research methods

Physical model

The physical model of cylindrical beef roll in the thawing process of heat transfer shown in Figure 1, establish unsteady numerical model of cylindrical food [6]:

$$\rho c_p \frac{\partial T}{\partial \tau} = K\left(\frac{\partial^2 T}{\partial r^2} + \frac{1}{r}\frac{\partial T}{\partial r}\right) \tag{1}$$

The initial conditions: $\tau = 0 \quad T = T_0 \ (0 <= r <= R)$;

Boundary conditions: $\begin{cases} r = 0 & \dfrac{dT}{dr} = 0 \ (heat\ isolution) \\ r = R & -K\dfrac{dT}{dr} = h(T_R - T_f) \end{cases}$;

Numerical analysis

According to the shape of the beef roll, it can be regarded as a cylindrical, Placing the beef roll with the initial temperature of T=-20℃, radius R=32mm in the environment which temperature is 20℃and in 12℃ water thaw respectively under the natural state, the natural convection coefficient between beef roll and surrounding air is h_1 and the natural convection heat transfer coefficient between beef roll and water is h_2. Heat exchange between beef roll's surface and the surrounding air is in accordance with Newton's law of cooling and the heat of each point of the cylinder's outer surface is the same, so the cylindrical food temperature distribution along the diameter direction is symmetric [5]. In order to study the process conveniently, coordinate origin at the center of the circle, only study the parameters variation along the radius direction, its physical model is shown in figure 1. Figure 2 is the center node grid. Using finite difference method establishes the equation.

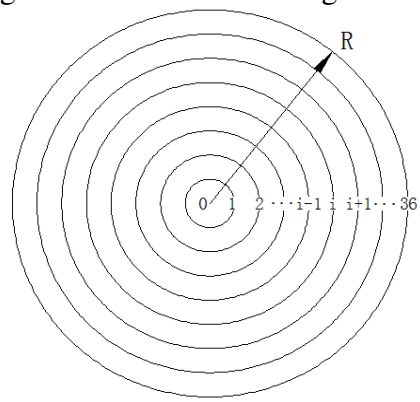

Fig.1. Heat transfer physical model

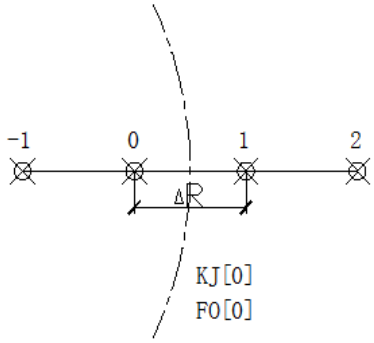

Fig.2.The center node grid of cylindrical food

As shown in Figure 1, using external node method to divide n-1 internal unit and two semi-unit (located in the center and the surface boundary) along the radius direction, in the figure solid line is the position line where the control node locates, there are n+1 nodes, $\Delta r = R/n$ is the spatial location step; $\Delta\tau$ is time step; In each unit take temperature as a lumped parameter approximation rather than the distribution function [5]. At the same time, in order to make the results convergence, control equation uses the implicit. In this way the results can be guaranteed unconditional convergence. When the central node temperature T<=0.5℃, the iteration process is over.

Establish difference equation

Shown in Figure 2, with the Taylor series expansion of the central node number 0 to establish the equation:

$$\rho c_p \frac{T_0^1 - T_0^0}{\Delta\tau} = 2KJ_0 \frac{T_{-1}^1 - 2T_0^1 + T_1^1}{\Delta r^2} = 4KJ_0 \frac{T_1^1 - T_0^1}{\Delta r^2} \quad (2)$$

$$\Rightarrow (1+4Fo_0)T_o^1 = 4Fo_0 T_1^1 + T_0^0$$

Figure 3 for the internal nodes meshing diagram, with element balance method for an internal node i establishment node equations:

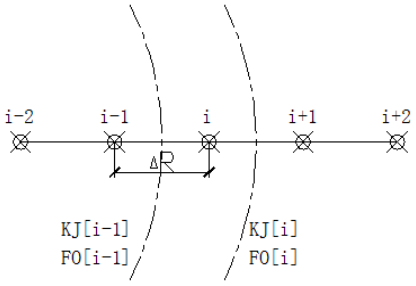

Fig.3.Internal nodes meshing diagram

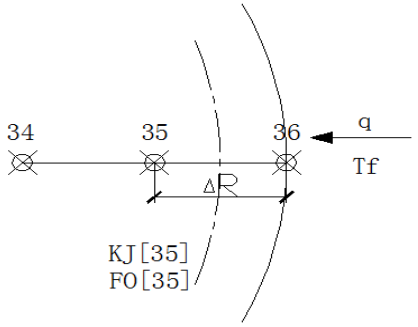

Fig.4.Boundary nodes meshing diagram

$$\rho c_p V_i \frac{T_0^1 - T_0^0}{\Delta\tau} = KJ_{i-1} \frac{T_{i-1}^1 - T_i^1}{\Delta r} F_w + KJ_i \frac{T_{i+1}^1 - T_i^1}{\Delta r} F_e \quad (3)$$

$$\Rightarrow (1+Fo_{i-1}+Fo_i)T_i^1 = (1+\frac{1}{2i})Fo_i T_{i+1}^1 + (1-\frac{1}{2i})Fo_{i-1}T_{i-1}^1 + T_i^0$$

Figure 4 for the boundary nodes meshing diagram, using Taylor series expansion method for boundary nodes 36 establishes node equation:

$$-KJ_{35} \frac{T_N^1 - T_{N-1}^1}{\Delta r} = h(T_N^1 - T_f) \quad (4)$$

$$\Rightarrow (1+Bi)T_N^1 = T_{N-1}^1 - BiT_f$$

Where: Δr for the space step, the value is 0.001m; $\Delta\tau$ is the time step, the value is 20s; T_i^1 is the temperature of n+1 moment; T_i^0 is the temperature of n moment, KJ_i is the thermal conductivity of the i number of the control body on the right interface, $KJ_i=2K_iK_{i+1}/(K_i+K_{i+1})$; K_i is the thermal conductivity of i node, According to the known thermal conductivity of frozen beef, it obtained by fitting equation about the relationship between the thermal conductivity and temperature, $K=-0.0001T^3-0.0062T^2-0.1407T+0.4848$(-30<=$T$<=0); T>0 K=0.48W/(m·℃); ρ is the density of beef, The values is 1050Kg/m³; C_p is the specific heat of beef, according beef freezing temperatures -2℃ to define Cp values, When T <=-2 Cp=3230J/(kg·℃); When T>-2℃ Cp=1720 J/（kg·℃）; Fo_i is the i number of Fourier number right boundary of the control volume, the formula is $Fo_i=KJ_i\Delta\tau/(\rho c_p\Delta r^2)$; Bi is the biot number.

Equation solving

Based on the TDMA method for physical model solving process, where *T[i]* represents the temperature of node i, when the temperature of the center node is not less than 0.5℃ iteration ended; M represents the number of iterations.

Results and discussion

With experimental and theoretical solved, the results obtained will be drawn into the thawing temperature change with time curve in the air and the thawing temperature change with time curve in the water, as shown in Figure5, 6. Due to space limitations, the figure shows only part of important nodes in temperature, such as the central nodes, *R/2* nodes, the boundary nodes. In addition, the theory of air and water thawing time compared with the experimental value is shown in Figure 7, 8.

From the curve in the figure, theoretical and experimental results are basically consistent, but inevitably there are errors, the numerical calculation shows that the error between the theoretical and experimental air thaw thawing time is 7.8% and water thaw thawing time is 8.4%.

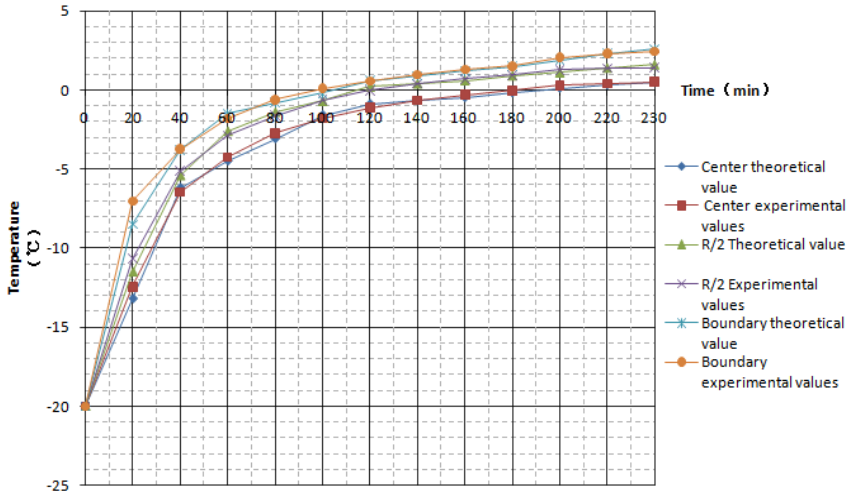

Fig.5.Thawing temperature by hourly value curve in the air

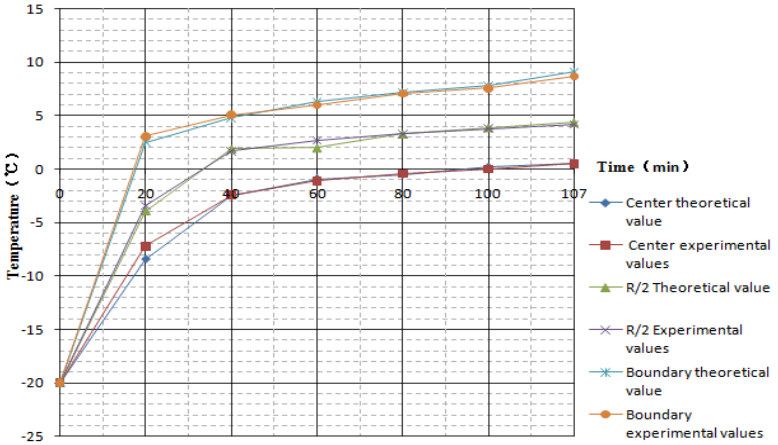

Fig.6.Thawing temperature by hourly value curve in the water

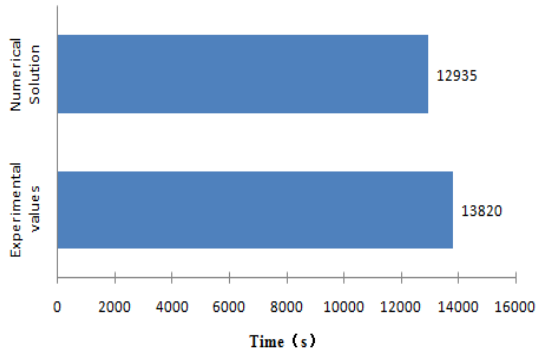

Fig.7.Air thawing time experimental and numerical value contrast

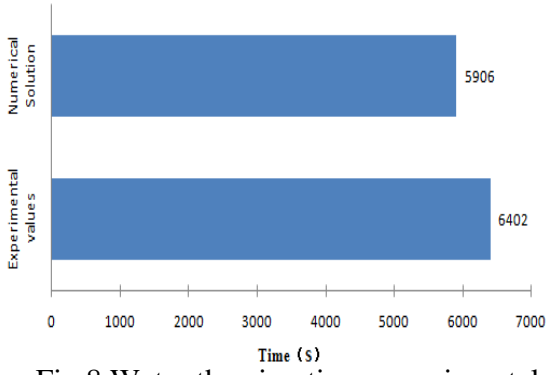

Fig.8.Water thawing time experimental and numerical value contrast

Meanwhile, Comparison of the two thawing ways the maximum error in the central region temperature is 1.2℃, the maximum error of temperature of *R/2* is 0.8℃, and the maximum error of the temperature of the boundary nodes is 1.5℃. The main reasons for generating the errors are:

a. Physical model established ignores the radiation heat transfer effects on the whole process.

b. Experimental instrument error due to the precision problems.

c. Be measured beef roll with a plastic film packaging make surface thermal resistance increase and weaken the heat transfer process, on the other hand, due to the moisture migration in the process of thawing will make its physical parameters change, which will make the experimental and theoretical results generate errors.

d. In the thawing process surrounding partial environment is not stable conditions.
e. The thawing ignores the axial heat conduction process.
f. Errors caused by human action, such as thermocouple probe buried point bias position.

Conclusion

(1) The solution that freezes thawed time and temperature distribution has important guiding significance and practical significance for the logistics process in the cold chain system. For example, in the condition of environmental temperature known, internal temperature of the frozen food is obtained by numerical calculation will change with time, this will play an important role in guiding when open the refrigeration unit of refrigerated truck. In the case of freezing temperatures to ensure the cold chain logistics process makes refrigeration units to reduce working hours in order to reduce energy consumption to achieve the energy saving effect.

(2) Through the numerical and experimental for thawing time which include water thaw and air thaw, more accurately predict the thawing time can be obtained, it has a certain guiding significance for the catering industry.

(3) If considering the axial heat and radiation heat transfer, calculation results with the experimental results will be more satisfactory.

Keywords: OFDM-RoF; channel estimation; DFT; the changing rate of energy.

Abstract. In this paper, we present a modified discrete Fourier transform (DFT)-based channel estimation method. The conventional DFT-based method will produce additional high frequency component in the channel impulse response, and degrade the accuracy of channel estimation. The modified algorithm can eliminate additional high frequency components by extending the LS estimate in frequency domain with a symmetric signal of its own, and selects the useful paths by calculating the changing rate of energy. Thus, the proposed algorithm become more accurate. The simulation results show the new algorithm can reduce the influence of noise on channel estimation efficiently, and the performance of the improved method is better than the LS and conventional DFT algorithm.

Introduction

OFDM can not only effectively enhance the transmission rate and capacity, but also combat multipath fading and inter-symbol interference (ISI) effectively [1]. RoF (Radio over Fiber) is a technique which uses the fiber to transport the high frequency microwave, millimeter wave or millimeter wave that carry information [2-3]. Combine OFDM with RoF, this system has the feature of high spectrum utilization, anti-electromagnetic interference and anti-dispersion. The receiver needs to know the channel information. So channel estimation is directly related to the performance of OFDM-RoF.

Many channel estimation algorithms have been presented. Least Square (LS) algorithm [4] has a low complexity. However, it is very sensitive to the noise, and has a larger mean square error. The conven- tional DFT-based channel estimation is an improved LS algorithm [5], which can reduces the noise in time domain. But the algorithm also has disadvantage, it will generate additional high frequency component when dealing with the discontinuous frequency response by FFT. If the component which is mistaken for noise is removed, the performance of the algorithm will decrease. In this paper, we propose an improved DFT algorithm, this algorithm use symmetry principle before IFFT to eliminate the impact of high frequency component. And then we will select useful paths effectively by calculating the changing rate of the energy. The channel estimation becomes more accuracy by above process.

OFDM-RoF System Model

Fig. 1 shows typical diagram of OFDM. The upper part of the channel is the transmitter, and the lower part of the channel is receiver. At the transmitter, incoming high-speed binary data is first converted into N parallel low-speed data streams and mapped according to a pre-specified modulation. After pilot insertion, the data $X(k)$ is sent to an IFFT block and transformed into time domain signal $x(n)$. In order to prevent inter-symbol interference (ISI), the cyclic prefix which contains a copy of the last part of an OFDM symbol is used. At the receiver, the binary will be obtained by the opposite processing.

Fig. 2 is a diagram of an OFDM-RoF system. The laser which is modulated by Mach-Zehnder Modulator (MZM) becomes an optical signal that has two different frequencies. After that, the optical becomes two beams of different frequencies of optical signal through different center frequency optical band pass filter. One of the two optical signal modulated by baseband OFDM symbol, then

coupling two optical signals into Single Mode Fiber (SMF). In order to ensure the quality of the optical signal, the optical amplifier is added to the system [6].At the receiver, we can use the optoelectronic detector to obtain the millimeter-wave electrical signal, and the frequency is the difference between frequencies of the optical signals. Then baseband OFDM symbol will be got by mixing and filtering.

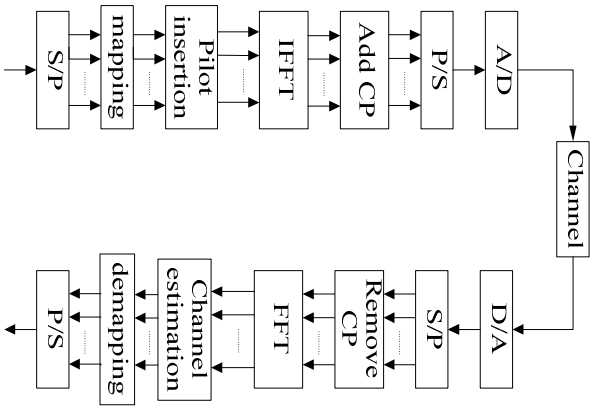

Fig. 1. The diagram of OFDM systems

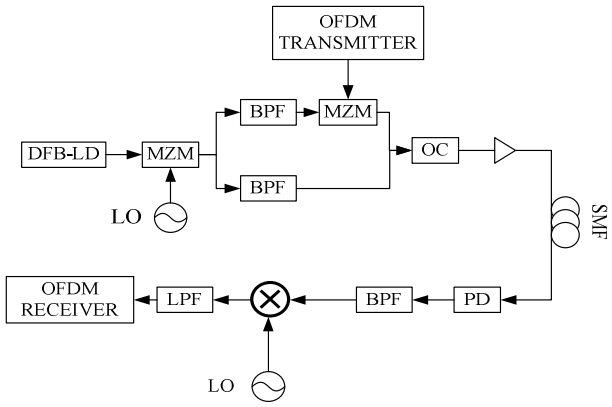

Fig. 2. The diagram of OFDM-RoF systems

A Modified Channel Estimation Metheod

LS algorithm is the simplest channel estimation. Assuming all subcarriers of the OFDM symbols are transmitted pilots, we can obtain the frequency response of the channel:

$$\hat{H}_{ls} = \frac{Y(k)}{X(k)} = H(k) + \frac{W(k)}{X(k)} \quad 0 < k < N-1 \tag{1}$$

LS algorithm is sensitive to noise, so it has a large MSE. In OFDM system, the length of the channel impulse response L is usually less than the length of the cyclic prefix L_g . Hence, conventional DFT channel estimation algorithm just takes advantage of this feature. It transforms the frequency response in frequency domain into impulse response in time domain, considers the part which is larger than L_g as noise, and then treats that part as zero in order to eliminate the noise of the impulse response.

If the original sequence is not continuous, DFT will generate additional high frequency component. In order to minimize the influence of high frequency component, we can preprocess the discontinuous sequence before IFFT. We use symmetry principle to make the sequence continuous. Moreover, we will select paths effectively by calculating the changing rate of the energy. The steps are as follows:

Step 1: Get the frequency response $\hat{H}_{ls}$ by LS algorithm;

Step 2: Extend $\hat{H}_{ls}$ with a symmetric signal of its own, so the original sequence becomes continuous, and the high frequency component can be eliminated effectively.

$$\hat{H}_{symmetric}(k) = \begin{cases} \hat{H}_{ls}(k) & 0 \le k \le N-1 \\ \hat{H}_{ls}(2N-1-k) & N \le k \le 2N-1 \end{cases} \tag{2}$$

Step 3: Transform $\hat{H}_{sym}(k)$ into time domain by IFFT:

$$\hat{h}_{symmetric}(n) = IDFT_{2N}\left[\hat{H}_{symmetric}(k)\right] \quad 0 \le n \le 2N-1 \tag{3}$$

Step 4: Select useful paths by calculating the changing rate of energy, useful paths will be reserved and other paths are set to zero. The energy of the channel impulse response can be expressed as:

$$E = \sum_{n=0}^{2N-1} \left|\hat{h}_{symmetric}(n)\right|^2 \tag{4}$$

the energy concentrates at the two ends of the sequences, So (7) can be written as:

$$E=\sum_{n=0}^{N-1}\left|\hat{h}_{symmetric}(n)\right|^{2}+\sum_{n=0}^{N-1}\left|\hat{h}_{symmetric}(2N-1-n)\right|^{2}=\sum_{n=0}^{N-1}E(n) \tag{5}$$

Where $E(n)$ is the sum of the energy of n-th and ($2N-1-n$)-th sampling points. The energy of front l paths can be expressed as:

$$E'(l)=\sum_{n=0}^{l}E(n)\ ,\quad 0\le l\le N-1 \tag{6}$$

$P(l)$ is defined as the changing rate of the energy. It represents the ratio of the energy of l-th path and the sum energy of front l paths.

$$P(l)=\frac{E'(l)-E'(l-1)}{E'(l)}\ ,\qquad 1\le l\le N-1 \tag{7}$$

We set an initial changing rate of the energy P'. If $P(l)\ge P'$, it shows that the energy of l-th path and ($2N$-1-l)-th path is large, these paths are useful and preserved. If $P(l)<P'$, this path is useless and superfluous. It will set to zero to eliminate noise. Then the channel response can be expressed as:

$$\tilde{h}_{DFT}(n)=\begin{cases}0 & l_{end}\le n\le 2N-1-l_{end}\\ \hat{h}_{symmetric}(n) & others\end{cases} \tag{8}$$

Where l_{end} is the last path which $P(l)$ is larger than P'. If l_{end} is larger than the length of CP, $l_{end}=L_g$.

Step 5: After padding with zeros, transform $\tilde{h}_{DFT}(n)$ to frequency domain by FFT:

$$\tilde{H}_{DFT}(k)=DFT_{2N}\left[\tilde{h}_{DFT}(n)\right]\ ,\qquad 0\le k\le 2N-1 \tag{9}$$

Step 6: According to the symmetric property, the corresponding frequency response is expressed as:

$$\hat{H}_{DFT}(k)=\frac{\tilde{H}_{DFT}(k)+\tilde{H}_{DFT}(2N-1-k)}{2}\ ,\quad 0\le k\le N-1 \tag{10}$$

Simulation Results

In this simulation, we use Optisystem and Matlab to build OFDM-RoF system. The baseband OFDM signal generated by Matlab. The rate of bit is 2.5Gb/s, the number of subcarriers is 512, the length of CP is 64. The parameters are shown in Table 1

Table 1 Simulation Parameters

The rate of bit	Mapping mode	Number of subcarriers	Fiber type	Fiber dispersion at 1550nm	The frequency of laser	Frequency of local oscillator
2.5Gb/s	16-QAM	512	SMF	17 ps/km-nm	193.13THz	30GHz and 60GHz

Fig. 3 shows the output constellation map without channel estimation. Due to the fiber dispersion effects, the constellation map is rotated, which will lead to incorrect judgments of transmitted signals.

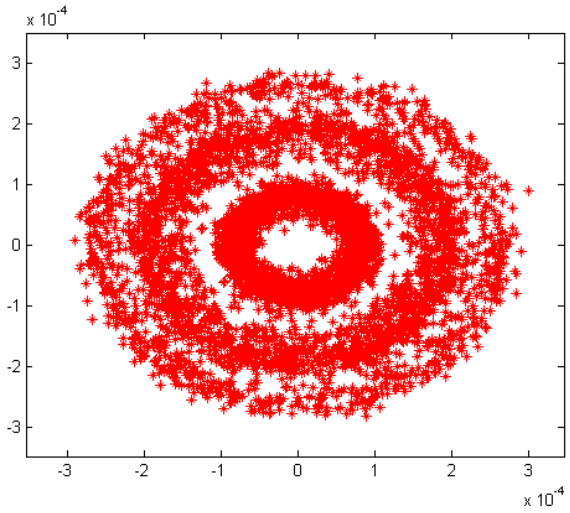

Fig.3. The output constellation map without channel estimation

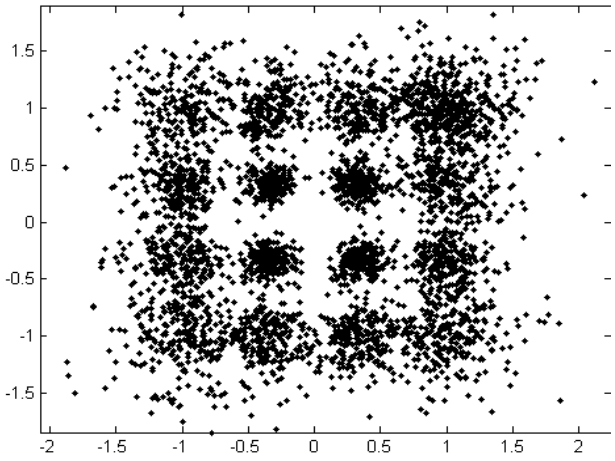

Fig.4. The output constellation map with the LS channel estimation

Fig. 4 is the output constellation map with the LS channel estimation algorithm. Obviously, this algorithm overcomes the impact of fiber chromatic dispersion, however, the noise influence still causes strong constellation dispersion, which degrades the BER performance of OFDM-RoF system.

Fig. 5 shows the output constellation map with the improved DFT channel estimation algorithm, and the constellation dispersion has been mitigated. Fig.6 demonstrates the BER performance of the improved algorithm, which adopts the symmetry principle and the energy changing rate of 0.19%, and limits the number of the selected paths less than the length of cyclic prefix. Because we accurately select the useful paths by calculating the changing rate of energy, the imroved algorithm is better than the LS and the conventional DFT channel estimation methods. The symmetry principle is helpful to eliminate the additional high frequency component.

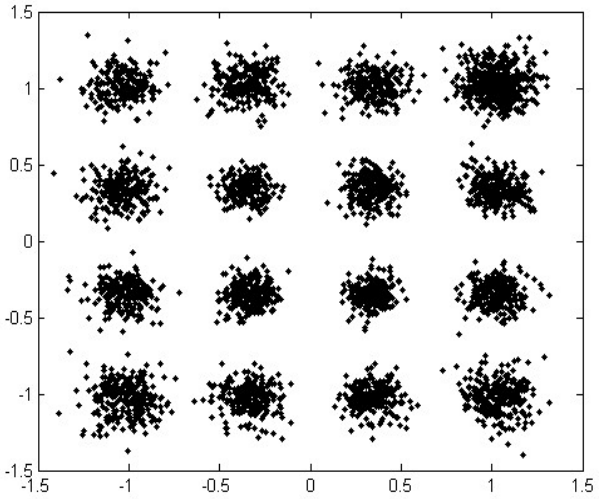

Fig. 5. The output constellation map with the improved DFT channel estimation algorithm estimation

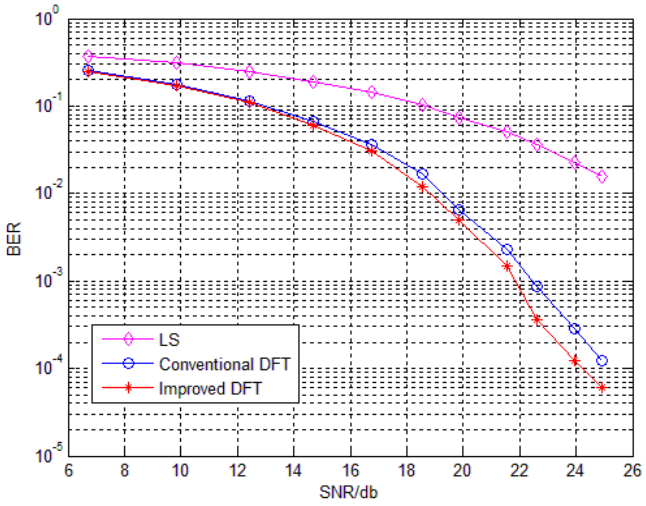

Fig. 6. BER comparison between the conventional and improved channel estimation algorithms

Summary

In this paper, an improved DFT channel estimation algorithm for OFDM-RoF is proposed. The improved algorithm uses the principle of symmetry and calculates the changing rate of energy to select useful paths efficiently and accurately. Simulation results show that BER performance of the improved method is better than LS estimation and conventional DFT channel estimation method. The improved method achieves a satisfying tradeoff between complexity and performance.

Keywords: bearings-only tracking, unscented filter, measurement model, data fusion

Abstract. This paper investigated the bearings-only tracking approach based on dual station detection. In order to solve the problem of strong nonlinearity in bearings –only measurement system, we introduced the unscented filter which is based on the idea of unscented transformation. Compared with traditional extended Kalman filter, unscented filter has shown better convergence and stabiltiy, especially in stabiltiy of tracking waveform. Matlab simulation scenario is taken for illustrating the effectiveness and validity of the unscented filtering algorithm.

Introduction

Bearings-only target tracking is a typical nonlinear estimation and filtering problem in signal processing [1-3]. In order to solve this problem, the most commonly used method is the extended Kalman filter (EKF) [4]. For bearings-only tracking, EKF behaves poor convergence because of the strong nonlinearity of the bearings-only measurement system. Even in many cases, the EKF is not convergent. This is because in EKF algorithm the measurement equation is approximated by linear transformation of the observation function.

Aiming at the problem of biased transformation in EKF algorithm, Julier S. J. proposed the unscented transformation (UT) [5]. Unscented transformation greatly reduced the biasness and computational complexity. Based on the idea of unscented transformation, an algorithm called unscented filter (UF) or unscented Kalman filter (UKF) is developed for dealing with nonlinear estimation [6-8]. In bearings-only target tracking, UF has shown better convergence and stability, especially in stability of tracking waveform compared with EKF.

Bearings-only measurement system model

For dual station based bearings-only target tracking system, we can acquire two measurement data in one observation cycle which are detected by two mutually independent observer stations. Compared with single observer platform, the system information has greatly increased. Obviously, the filtering convergence and stability in dual station-based system will get huge improvement. At the same time, the measurement data is acquired from two different stations, in order to obtain better target tracking trajectories, we need to consider how to fusion the measurement information in the filtering algorithms. In theory, this problem belongs to the multi-sensor data fusion. The observer-to-target geometry in dual station based bearings-only measurement system is shown in Figure 1.

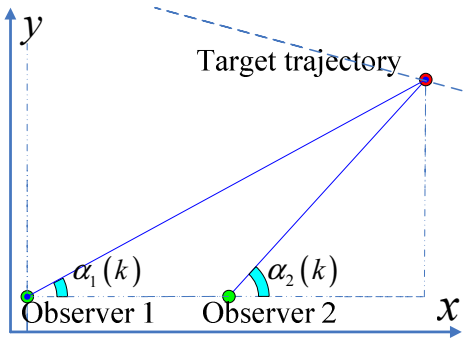

Fig. 1 The observer-to-target geometry

The position coordinates of observer 1 and observer 2 are known, designated by $\xi_1 = [S_{O1x}, S_{O1y}]^T$ and $\xi_2 = [S_{O2x}, S_{O2y}]^T$. The target state vector in time instant k is represented as

$$\eta(k) = [S_{Tx}(k), S_{Ty}(k), V_{Tx}(k), V_{Ty}(k)]^T \tag{1}$$

Target velocities are affected by random Gaussian noises defined as $v_1(k)$ and $v_2(k)$, which also can be interpreted as accelerations. The target state equation is

$$\eta(k+1) = A \cdot \eta(k) + v(k) \tag{2}$$

where $v(k) = [0, 0, v_1(k), v_2(k)]^T$ is process noise vector at time instant k,

$$A = \begin{bmatrix} 1 & 0 & T & 0 \\ 0 & 1 & 0 & T \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{3}$$

is target state transition matrix. Define $z(k) = [z_1(k), z_2(k)]^T$ as the measurement data of two observer stations at time instant k, $w(k) = [w_1(k), w_2(k)]^T$ as random Gaussian measurement noise which is mutually independent, the measurement equation is

$$z(k) = h[\eta(k), k] + w(k) \tag{4}$$

where

$$h[\eta(k), k] = \begin{bmatrix} h_1[\eta(k), k] \\ h_2[\eta(k), k] \end{bmatrix} = \begin{bmatrix} \alpha_1(k) \\ \alpha_2(k) \end{bmatrix} \tag{5}$$

$\alpha_1(k)$ and $\alpha_2(k)$ are the target bearings with regard to observer station 1 and observer station 2 which can be computed by following expression,

$$\begin{cases} \alpha_1(k) = \arctan \dfrac{\Delta y_1(k)}{\Delta x_1(k)} = \arctan \dfrac{S_{Ty}(k) - S_{O1y}}{S_{Tx}(k) - S_{O1x}} \\ \alpha_2(k) = \arctan \dfrac{\Delta y_2(k)}{\Delta x_2(k)} = \arctan \dfrac{S_{Ty}(k) - S_{O2y}}{S_{Tx}(k) - S_{O2x}} \end{cases} \tag{6}$$

In Formula (6), $\Delta x_1(k)$, $\Delta x_1(k)$, $\Delta x_2(k)$ and $\Delta y_2(k)$ are the relative distances between target and two observer stations in x and y coordinates. $\Delta r_1(k)$ and $\Delta r_2(k)$ are the range between target and observer stations which can be computed by following equation,

$$\begin{cases} \Delta r_1(k) = \sqrt{\Delta x_1(k)^2 + \Delta y_1(k)^2} \\ \Delta r_2(k) = \sqrt{\Delta x_2(k)^2 + \Delta y_2(k)^2} \end{cases} \tag{7}$$

The unscented filtering algorithm

The unscented filter can be derived by substituting the mean and covariance updating equations in EKF with the unscented transform. The unscented filtering algorithm consists of the following steps:

1. Computing one-step prediction of the means and covariance for system state variables at time instant k. Firstly we choose $2n$ samples:

$$\hat{x}_{k|k}^{(i)} = \hat{x}^{+}(k \mid k) + \tilde{x}^{(i)} \quad i = 1, \cdots, 2n \tag{8}$$

2. Using nonlinear function f in target state equation to transform $2n$ samples:

$$\hat{x}_{k}^{(i)} = f[\hat{x}_{k|k}^{(i)}, u(k), k] \quad i = 1, \cdots, 2n \tag{9}$$

3. Calculating one-step predictive mean and covariance of target state at time instant k:

$$\hat{x}^{+}(k+1 \mid k) = \frac{1}{2n} \sum_{i=1}^{2n} \hat{x}_{k}^{(i)} \tag{10}$$

$$P_x(k+1 \mid k) = \frac{1}{2n} \sum_{i=1}^{2n} \left[\hat{x}_{k}^{(i)} - \hat{x}^{+}(k+1 \mid k) \right] \left[\hat{x}_{k}^{(i)} - \hat{x}^{+}(k+1 \mid k) \right]^{T} + Q(k) \tag{11}$$

4. Calculating one-step predictive mean and covariance of measurement:

$$x_{k+1|k}^{(i)} = \hat{x}^{+}(k+1 \mid k) + \tilde{x}^{(i)} \quad i = 1, \cdots, 2n \tag{12}$$

5. Using nonlinear function h in measurement equation to transform $2n$ samples:

$$\hat{y}_{k}^{(i)} = h[\hat{x}_{k+1|k}^{(i)}, k] \quad i = 1, \cdots, 2n \tag{13}$$

6. Calculating one-step predictive mean and covariance of state:

$$\hat{y}^{+}(k+1 \mid k) = \frac{1}{2n} \sum_{i=1}^{2n} \hat{y}_{k}^{(i)} \tag{14}$$

$$P_y(k+1 \mid k) = \frac{1}{2n} \sum_{i=1}^{2n} \left[\hat{y}_{k}^{(i)} - \hat{y}^{+}(k+1 \mid k) \right] \left[\hat{y}_{k}^{(i)} - \hat{y}^{+}(k+1 \mid k) \right]^{T} + R(k+1) \tag{15}$$

7. State and covariance updating:

$$\begin{cases} W(k+1) = P_{xy} \cdot P_{y}^{-1} \\ \hat{x}^{+}(k+1 \mid k+1) = \hat{x}^{+}(k+1 \mid k) + W(k+1) \cdot [y(k+1) - \hat{y}^{+}(k+1 \mid k)] \\ P^{+}(k+1 \mid k+1) = P_x(k+1 \mid k) - W(k+1) P_y(k+1 \mid k) W(k+1)^{T} \end{cases} \tag{16}$$

Simulation and result analysis

Table 1 gives the parameters configuration for Matlab simulation scenario. The observation period is 1 simulation second. The initial state estimates and covariance are chosen as follows.

$$\eta(0) = \begin{bmatrix} 4050 & 5050 & 0 & 0 \end{bmatrix}^{T} \tag{17}$$

$$P(0) = \begin{bmatrix} 10 & 0 & 0 & 0 \\ 0 & 10 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{18}$$

Table 1 Parameters configuration for simulation scenario

Number of observations	Target position	Observer positions	Measurement noise
150	(4000m,5000m)	(-2000m,0m), (2000m,0m)	**1°**

Figure 2 shows the target tracking trajectory and true trajectory with unscented filter.

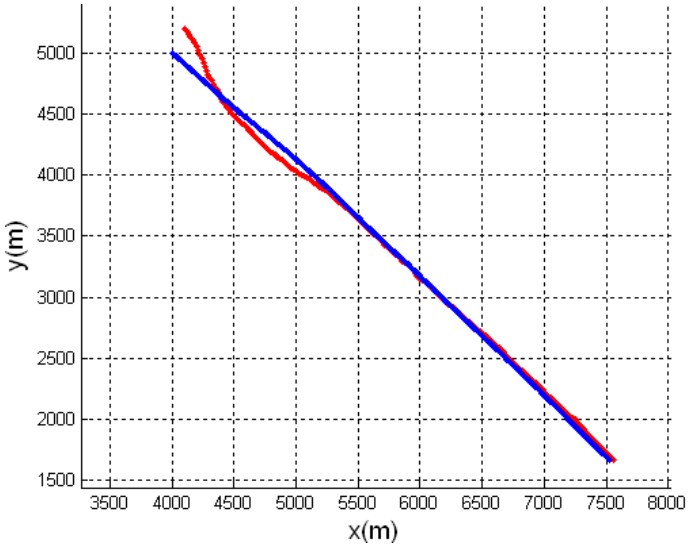

Fig. 2 Target tracking trajectory

Summary

This paper discussed the target tracking problem in dual station based bearings-only measurement system. The unscented filter is used in virtue of the strong linearity. First, the system model is given with target motion equation and observer measurement equation. Second, we introduced the unscented filtering algorithm which is based on unscented transformation. Finally, the Matlab simulation scenario is taken for illustrating the effectiveness and validity of the algorithm. From the simulation result, we can see that the unscented filter greatly reduced the biasness and computational complexity. Especially in bearings-only target tracking, the unscented filter has better convergence and stability compared with EKF.

Keywords: Mobile, Wireless communications, Buffered clock, Network

Abstract. The microprocessor generates many digital noises that find their way back from the clock reference input of the microprocessor to the reference clock lines with which the RF circuits are sharing. These digital noises are conductively coupled to the RF circuits, including any RF transceiver, Bluetooth module and other RF circuits, such as a local oscillator and phase locked loop circuits, to cause spurious signals and jitters in the circuits, which in turn, degrade the RF performance or cause a radio to fail certain specifications.

Introduction

Mobile wireless communications devices, such as cellular telephones and similar communications devices, include a housing and circuit board carried by the housing. A microprocessor, radio frequency (RF) transceiver and RF circuitry can be carried by the circuit board and operative with each other. An antenna could be located external or within the housing. A clock, such as a crystal oscillator, could be positioned external to the components and off the circuit board or mounted on the circuit board, and provide a clocking signal to the microprocessor[1], RF transceiver and other RF circuitry, including any Bluetooth modules, phase locked loop circuits, and local oscillator (LO) circuits. Typically, spurious signals and jitters caused by digital noise from a microprocessor creates problems because it shares the same clock with the RF circuits, such as the reference clock input to the phase locked loop. The clock from the crystal oscillator provides the reference clock input signal to both the RF circuits, such as the phased locked loop circuit, RF circuits and digital circuits, such as the microprocessor, but without buffering[2].

Mobile wireless communications device design mechanism

This is aiming at solving the aforementioned defects, providing an IoT intelligent gas meter and its control system based on the transmission of IoT, and adopting supporting network management system. Many different forms can be set forth and described embodiments should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope to those skilled in the art. Like numbers refer to like elements throughout, and prime notation is used to indicate similar elements in alternative embodiments.

A mobile wireless communications device includes a housing and a circuit board carried by the housing. A microprocessor, a radio frequency (RF) transceiver and RF circuitry are carried by the circuit board and operative with each other. Clock buffer circuitry is carried by the circuit board and connected to the RF transceiver, RF circuitry and microprocessor for isolating a clock signal from the noise of the microprocessor and allowing greater isolation for the RF transceiver from RF circuitry[3].

The RF circuitry includes a Bluetooth module and the clock buffer circuitry is connected to the Bluetooth module for isolating a clock signal after the RF transceiver. The RF circuitry could also include a phase locked loop circuit and the clock buffer circuitry is connected to the phase locked looped circuit for isolating a clock signal after the RF transceiver and Bluetooth module.

The RF transceiver is formed as a GSM/GPRS (Global System for Mobile communications/General Packet Radio Service) system. The clock buffer circuitry could be formed as a plurality of serially connected buffers each having an output connected to a predetermined one of the RF circuitry and microprocessor. Each buffer could provide about to about 80 decibels of reversed isolation from its output to its input in a non-limiting example. The plurality of serially connected buffers could also be formed as transistors connected as emitter followers. The housing can be configured for handheld operation and the RF transceiver, RF circuitry and microprocessor can be operative as a cellular communications device. An antenna could be carried by the housing and operative with the RF transceiver[4].

The implementation of an example of mobile wireless communication

Different embodiments show that different clock signals can be isolated from the noise of the microprocessor. More sensitive RF circuits, for example, the GSM/GPRS chip set, could be connected to the crystal oscillator output first with proper impedance matching. The output of a first buffer circuit could be connected to a less sensitive RF circuit, for example, a Bluetooth module or chip. The buffer circuit could provide about to about 80 decibel reversed isolation from its output to the input. Other buffer circuits could be included with separate isolation.

A brief description will now proceed relative to FIGS. 1- which disclose an example of a mobile wireless communications device, for example, a handheld portable cellular radio, which can incorporate the non-limiting examples of the various buffering circuits and clock distribution network. FIGS. 1-are representative non-limiting examples of the many different types of functional circuit components and their interconnection, and operative for use with the clock distribution network and buffering circuits as described.

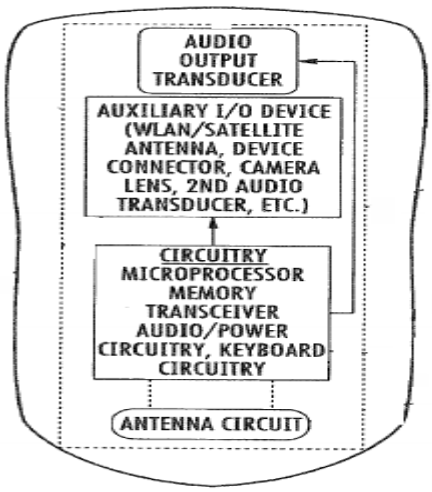

FIG. 1

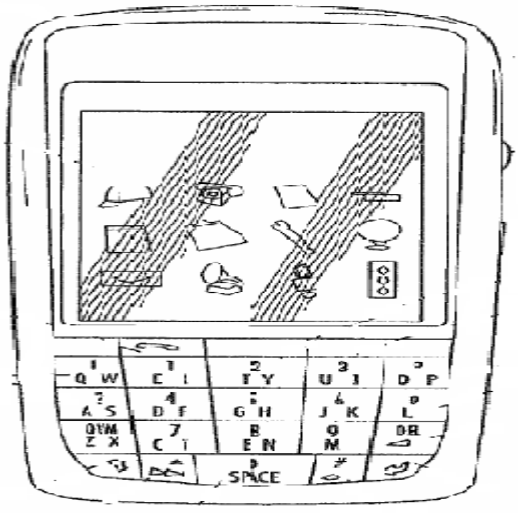

FIG. 2

Referring initially to FIGS. 1 and an example of a mobile wireless communications device , such as a handheld portable cellular radio, which can be used with the present invention is first described. This device illustratively includes a housing having an upper portion and a lower portion , and a dielectric substrate (i.e., circuit board) , such as a conventional printed circuit board (PCB) substrate, for example, carried by the housing. A housing cover (not shown in detail) would typically cover the front portion of the housing. The term circuit board as used hereinafter can refer to any dielectric substrate, PCB, ceramic substrate or other circuit carrying structure for carrying signal circuits and electronic components within the mobile wireless communications device . The illustrated housing is a static housing, for example, as opposed to a flip or sliding housing which are used in many cellular telephones. However, these and other housing configurations may also be used[5].

Circuitry is carried by the circuit board , such as a microprocessor, memory, one or more wireless transceivers (e.g., cellular, WLAN, etc.), which includes RF circuitry, including audio and power circuitry, including any keyboard circuitry. It should be understood that keyboard circuitry could be on a separate keyboard, etc., as will be appreciated by those skilled in the art. A battery (not shown) is also preferably carried by the housing for supplying power to the circuitry . The term RF circuitry could encompass the interoperable RF transceiver circuitry, power circuitry and audio circuitry.

Furthermore, an audio output transducer (e.g., a speaker) is carried by an upper portion of the housing and connected to the circuitry . One or more user input interface devices, such as a keypad (keyboard) FIG. , is also preferably carried by the housing and connected to the circuitry . The term keypad as used herein also refers to the term keyboard, indicating the user input devices having lettered and/or numbered keys commonly known and other embodiments, including multi-top or predictive entry modes. Other examples of user input interface devices include a scroll wheel and a back button . Of course, it will be appreciated that other user input interface devices (e.g., a stylus or touch screen interface) may be used in other embodiments.

An antenna is preferably positioned at the lower portion in the housing and can be formed as a pattern of conductive traces that make an antenna circuit, which physically forms the antenna. It is connected to the circuitry on the main circuit board . In one non-limiting example, the antenna could be formed on an antenna circuit board section that extends from the circuit board at the lower portion of the housing. By placing the antenna adjacent the lower portion of the housing , the distance is advantageously increased between the antenna and the user's head when the phone is in use to aid in complying with applicable SAR requirements. Also, a separate keyboard circuit board could be used.

More particularly, a user will typically hold the upper portion of the housing very close to his head so that the audio output transducer is directly next to his ear. Yet, the lower portion of the housing where an audio input transducer (i.e., microphone) is located need not be placed directly next to a user's mouth, and can be held away from the user's mouth. That is, holding the audio input transducer close to the user's mouth may not only be uncomfortable for the user, but it may also distort the user's voice in some circumstances. In addition, the placement of the antenna adjacent the lower portion of the housing also advantageously spaces the antenna farther away from the user's brain.

Another important benefit of placing the antenna adjacent the lower portion of the housing is that this may allow for less impact on antenna performance due to blockage by a user's hand. That is, users typically hold cellular phones toward the middle to upper portion of the phone housing, and are therefore more likely to put their hands over such an antenna than they are an antenna mounted adjacent the lower portion of the housing . Accordingly, more reliable performance may be achieved from placing the antenna adjacent the lower portion of the housing .

Still another benefit of this configuration is that it provides more room for one or more auxiliary input/output (I/O) devices to be carried at the upper portion of the housing. Furthermore, by separating the antenna from the auxiliary I/O device(s) , this may allow for reduced interference therebetween.

Some examples of auxiliary I/O devices include a WLAN (e.g., Bluetooth, IEEE 8011) antenna for providing WLAN communication capabilities, and/or a satellite positioning system (e.g., GPS, Galileo, etc.) antenna for providing position location capabilities, as will be appreciated by those skilled in the art. Other examples of auxiliary I/O devices include a second audio output transducer (e.g., a speaker for speaker phone operation), and a camera lens for providing digital camera capabilities, an electrical device connector (e.g., USB, headphone, secure digital (SD) or memory card, etc.).

Summary

Accordingly, the mobile wireless communications device as described may advantageously be used not only as a traditional cellular phone, but it may also be conveniently used for sending and/or receiving data over a cellular or other network, such as Internet and email data, for example. Of course, other keypad configurations may also be used in other embodiments. Multi-tap or predictive entry modes may be used for typing e-mails, etc. as will be appreciated by those skilled in the art.

Keywords: Airborne three-line array CCD Sensor, Direct Geo-positioning, Self-Calibration，Block Adjustment, ADS40/80

Abstract. On the basis of establishing direct geo-positioning model for three-line array sensor ADS40/80 images, in order to optimize the positioning accuracy, the self-calibration technology was used to update the ADS40/80 sensor imaging parameters. Moreover, the ADS40/80 camera error model and self-calibration bundle adjustment model were set up. Multi-groups of ADS40 data over the Songshan experimental field were used for direct geo-positioning and parameter updating experiments. Experimental results proved that the self-calibration adjustment technique can effectively update sensor imaging parameters and significantly improve image direct positioning accuracy.

Introduction

For a long time, it is a goal been pursued by photogrammetry community of realizing direct remote sensing image geopositioning from space to ground by measuring spatial positions and attitudes of cameras at imaging moments and obtaining exterior orientation elements of projection beam (photograph) directly[1]. If the direct-geopositioning mode does not rely on ground control, the outdoor work strength can be greatly released and aerial mapping cycles can be significantly shortened. Undoubtedly, it has important application value especially for disaster-prone and harsh natural conditions areas, borders and other disputed areas that are difficult to carry out ground control survey work.

With the development of sensor devices and related technology, direct remote sensing image geopositioning without ground control is becoming a reality. In the aerial remote sensing field, an important feature of ADS40/80 representative airborne linear CCD sensor is the sensor integration technology, which constitutes the direct positioning and orientation system (Postioning and Orientaiton System-POS) through integrating GPS and inertial measurement unit IMU (Inertial Measurement Unit)[2]. The POS system can obtain exterior orientation elements at imaging moments in real time. In theory, direct geospotioning can be achieved for remote sensing images using POS data without ground control. However, the actual application showed that although direct geopostioning can be achieved for ADS40/80 images using POS data, but the accuracy indicators is still unable to meet the large scale mapping and precise targeting requirements. Now it is an important research direction to effectively optimize direct positioning accuracy upon the current research basis.

Based upon the analysis about ADS40/80 sensor, the direct geopositioning model is built to realize direct image geopositioning firstly. And then the self-calibration technology is introduced to update sensor imaging parameters and optimize the direct positioning accuracy. Finally, the full set of ADS40 aerial flight data over Songshan remote sensing testfield is used to validate and evaluate the direct geopositioning accuracy and the optimization effect.

1. ADS40/80 Airborne Digital Sensor

ADS40/80 is a multi-line CCD digital aerial camera launched by Leica Ltd. in 2000, after wards upgrading to ADS80. It takes the three-line array push-broom imaging mode, which can image the

ground target from three different angles (ie, front, nadir and backward) synchronously and obtain three viewing angle panchromatic and four multispectral (R, G, B, NIR) images simultaneously. For ADS40/80 camera, single lens is used and different band image is separated by three colors splitter. All bands of linear array CCD detector areplaced in the same focal plane plate and the arrangement of all CCD linear array shown is in Figure 1. Each group of panchromatic CCD imaging line is composed of two CCD linear arrays arranged in half-pixel displacement, and for four multi-spectral bands each band corresponds to one CCD line. Each CCD linear array contains 12,000 pixels and each pixel size is 6.25mm.

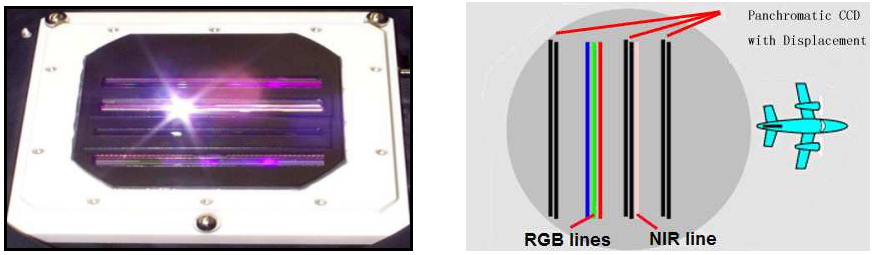

Fig. 1 Focal Plane Plate of ADS40/80 and Arrangement of CCD Linear Arrays

The main components of ADS40/80 camera include a sensor probe SH40, the control unit CU40, large capacity memory MM40, the operation display system OI40, navigation display system PI40 and gyro stabilized platform PAV30. Among them SH40 is the main optical imaging components, integrating optical lens system and IMU equipment. CU40 integrates GPS receiver and Applanix's POS / AV (Positioning and Orientation System for Airborne Vehicles) equipment and is mainly used to record synchronous photographic camera position and attitude data during flight. MM40 is primarily used to store video and GPS / IMU data, OI40 and PI40 is primarily used to provide a human-computer interactive interface.

2. The Direct Positioning Model of ADS40/80 Imagery

The ADS40/80 is a linear array CCD sensor and takes the pushbroom imaging mode. The scanning line acquired at each imaging moment has strict central projection relation with the ground imaged target and fulfills the line central projection relationship. Each scanning line has its own corresponding set of exterior orientation elements. If the instantaneous image plane coordinate system is established by taking the flight direction as x axis and the scanning direction as y axis, the instantaneous imaging equation is set up as.

$$\begin{bmatrix} x \\ y \\ -f \end{bmatrix} = \frac{1}{\lambda} R^{T} \begin{bmatrix} X - X_{Si} \\ Y - Y_{Si} \\ Z - Z_{Si} \end{bmatrix} \tag{1}$$

Dividing the former two equations in formula (1) by equation 3 and eliminating the scaling factor λ, the below formula can be gotten.

$$\begin{cases} x = -f \dfrac{a_1(X - X_{Si}) + b_1(Y - Y_{Si}) + c_1(Z - Z_{Si})}{a_3(X - X_{Si}) + b_3(Y - Y_{Si}) + c_3(Z - Z_{Si})} \\ y = -f \dfrac{a_2(X - X_{Si}) + b_2(Y - Y_{Si}) + c_2(Z - Z_{Si})}{a_3(X - X_{Si}) + b_3(Y - Y_{Si}) + c_3(Z - Z_{Si})} \end{cases} \tag{2}$$

In where (x, y) is coordinates of image point at instantaneous image plane coordinate system. For linear array image acquired by the same CCD, the x coordinates are all the same, and x always 0 for nadir image. For ADS40/80 images, the attached camera file recorded the coordinates of each CCD pixel center in the focal plane for all CCD linear arrays, and (x, y) can be queried from the camera file directly. (X,Y,Z) is the ground space coordinates of the corresponding ground point P. $(X_{Si}, Y_{Si}, Z_{Si}, \omega_i, \varphi_i, K_i)$ is the exterior orientation elements of the i-th scan line, R is the rotation

matrix formed by angle values (ω,φ,K),and $a_i,b_i,c_i(i=1,2,3)$ are elements in the rotation matrix $\boldsymbol{R}$. In this paper, the ω,φ,K angle system is taken.

Applying linearization on formula (2), we can obtain the linearized equation as follows,

$$\begin{cases} v_x = a_{11}\Delta X_S + a_{12}\Delta Y_S + a_{13}\Delta Z_S + a_{14}\Delta\omega + a_{15}\Delta\varphi + a_{16}\Delta\kappa - a_{11}\Delta X - a_{12}\Delta Y - a_{13}\Delta Z - l_x \\ v_y = a_{21}\Delta X_S + a_{22}\Delta Y_S + a_{23}\Delta Z_S + a_{24}\Delta\omega + a_{25}\Delta\varphi + a_{26}\Delta\kappa - a_{21}\Delta X - a_{22}\Delta Y - a_{23}\Delta Z - l_y \end{cases} \quad (3)$$

Where,

$$l_x = x + f\frac{\bar{X}}{\bar{Z}},\quad l_y = y + f\frac{\bar{Y}}{\bar{Z}},\quad \begin{cases} \bar{X} = a_1(X - X_{Si}) + b_1(Y - Y_{Si}) + c_1(Z - Z_{Si}) \\ \bar{Y} = a_2(X - X_{Si}) + b_2(Y - Y_{Si}) + c_2(Z - Z_{Si}) \\ \bar{X} = a_3(X - X_{Si}) + b_3(Y - Y_{Si}) + c_3(Z - Z_{Si}) \end{cases} \quad (4)$$

Obviously, if the interior and exterior orientation elements of the camera are known, formual (3) can be simplified as.

$$\begin{cases} v_x = -a_{11}\Delta X - a_{12}\Delta Y - a_{13}\Delta Z - l_x \\ v_y = -a_{21}\Delta X - a_{22}\Delta Y - a_{23}\Delta Z - l_y \end{cases} \quad (5)$$

Formula (5) is the error equation for the least-squares adjustment of multi-photo forward intersection. After the initial values are given out, ground coordinates (X,Y,Z)can be obtained by iterative computation. This is the direct ADS40/80 images positioning model adhpoted in this paper.

3. The Imaging Parameters Updating for ADS40/80 Based Self-calibration Technique

The self-calibration technique is based on the traditional photogrammetry theory and it is the most effective system error compensation method in analytical photogrammetry [5]. It basic idea is to treat the underlying systematic errors as undetermined parameters and absorb them into the overall adjustment for aerial block triangulation, which carries the optimal estimation on the main parameters and system error parameters simultaneously and assess accuracy. The final purpose is to eliminate or reduce system errors. Among various adjustment methods, the bundle block adjustment is most suitable for the introduction of additional parameters.

Considering the geometrical and physical factors in sensor imaging, if the self-calibration additional parameters can accurately reflect the systematic errors in sensor interior and exterior orientation elements and photographic lens optical distortions, the sensor geometric self-calibration can be successfully realized by the exact solution to the additional parameters through block adjustment[6]. This is the theoretical basis, for updating the ADS40/80 imaging parameters .

3.1 Fundamental Adjustment Equations

The basic formula of the self-calibration bundle block adjustment based on additional parameters is:

$$\left.\begin{aligned} x + \Delta x &= -f\frac{a_1(X - X_s) + b_1(Y - Y_s) + c_1(Z - Z_s)}{a_3(X - X_s) + b_3(Y - Y_s) + c_3(Z - Z_s)} \\ y + \Delta y &= -f\frac{a_2(X - X_s) + b_2(Y - Y_s) + c_2(Z - Z_s)}{a_3(X - X_s) + b_3(Y - Y_s) + c_3(Z - Z_s)} \end{aligned}\right\} \quad (6)$$

Where Δx and Δy represents the additional parameters function at the image point. If the control points are treated as the weighted observations, then the basic adjustment equations are listed as.

$$\begin{cases} V_X = A\Delta + C\Delta_S + B\dot{\Delta} - L_X & P_X \\ V_C = E\Delta_S - L_S & P_C \\ V_G = E\dot{\Delta} - L_G & P_G \end{cases} \quad (7)$$

Where V_X, V_G, V_C are the increment vectors of the image point, the ground control point and the self-calibration parameters observations respectively. $\dot{\Delta}$ is the increment vector of the unknown

ground coordinates, Δ is the increment vector of the unknown exterior orientation elements, Δ_S is the unknown self additional parameters; A, B, C are the coefficient matrixes corresponding to the unknowns; E are the identity matrixes, L_X is the constant observation vector for image point, L_S is observation value for self calibration parameters, L_G is observation value for for ground point; and the P_X, P_C, P_G are the corresponding weight matrixes.

3.2 Camera Error Model of ADS40/80

In order to compensate system errors effectively, a reasonable and effective self-calibration additional parameter model (ie camera error model) is particularly critical. Home and abroad scholars have carried out numerous investigation and put forward various parameter models, which can mainly be summarized into two types, namely polynomial type parameter model and the physical parameter model considering imaging aberration. Starting from the pure mathematics perspective, the former type does not consider the specific factors causing the point systematic error and does not emphasize the physical meaning of the additional parameters. It treats the combined effects of errors as a whole and uses a general form of polynomials as additional parameters. But the latter type starts from the physical factors causing the systematic errors for analyzing and designing the parameter model.

In the latter scenario, the 29-parameter model designed by Brown DC[7] has been widely used. Although the Brown model was originally designed for the film analog cameras, but applications demonstrate that it still applies for CCD digital sensor. In the ADS40/80 ORIMA adjustment software provided Leica, the used self-calibration module is modified form of Brown model, using a total of 18 additional parameters[8]. Its expression is as follows:

$$\begin{cases} dx = x_0 + a_1(r^2 - r_0^2)x + a_2(r^4 - r_0^4)x + a_3(r^6 - r_0^6)x + b_1x + b_2y \\ \quad + \dfrac{x}{f}\left[c_1(x^2 - y^2) + c_2x^2y^2 + c_3(x^4 - y^4)\right] + d_1xy + d_2y^2 + d_3x^2y + d_4xy^2 + d_5x^2y^2 \\ dy = y_0 + a_1(r^2 - r_0^2)y + a_2(r^4 - r_0^4)y + a_3(r^6 - r_0^6)y \\ \quad + \dfrac{x}{f}\left[c_1(x^2 - y^2) + c_2x^2y^2 + c_3(x^4 - y^4)\right] + d_6xy + d_7x^2 + d_8x^2y + d_9xy^2 + d_{10}x^2y^2 \end{cases} \quad (8)$$

In where (x_0, y_0) is coordinates of the principal point, f is the principal distance, a_1, a_2, a_3 are lens radial distortion parameters, b_1, b_2 are affine transform parameters, c_1, c_2, c_3 are photograph flatten parameters, $d_1 \ldots d_{10}$ are film deformation and lens non-radial distortion parameters, r_0 is principal point radial distance, r is the radial distance of image point, $r_0^2 = x_0^2 + y_0^2$, $r^2 = (x - x_0)^2 + (y - y_0)^2$.

4. Test and Analysis

4.1 Experimental Data

The used experimental data were ADS40 aerial remote sensing data s acquired over Songshan experimental field in August 2009. Through groups of data with the flying height being 600 m, 1000 m and 3000 m were selected for test and recorded as DataA, DataB and DataC. For DataA, the average flying height is about 600m and the average ground resolution is of 6cm. It includes two east-west routes and two north-south frame routes, and a total of 30 ground control points are selected from the coverage area. For DataB, the average flying height is approximately 1000m and the average ground resolution is 10cm. It comprises two east-west routes and a north-south frame route and 28 control points are picked out from the coverage area. For DataC, the average flying height is about 2900m and the corresponding ground resolution is 30cm, including two east-west routes and two north-south cross-routes and 35 chosen control points.

4.2 Experimental Methods and Results

1) Firstly, direct positioning experiments were carried out for three sets of data. Residuals on check points were statistically computed and the results were shown in Table 1, which calculated the maximum residual errors and the root mean squares (RMS) errors of check points. To facilitate the subsequent comparison, the RMS errors were computed in two standards meter and pixel resolution GSD.

2) Better quality data DataA and DataB were selected for self-calibration adjustment. The ORIMA software self-calibration module was used for self-calibration adjustment and to generate and extract the updated camera self-calibration file, denoted CamA and CamB (The raw camera file was denoted as Cam0).

3) The direct positioning test was carried out on three sets of data again using the new camera files CamA and CamB. Residuals on check points were statistically calculated and the results were shown in Table 2. The residual results were also converted into GSD standard. And comparison were made among direct positioning accuracy using Cam0 file, CamA file and CamB file respectively and the accuracy optimization results was evaluated and shown in Table 3.

Table 1. Direct Positioning Result of ADS40 data

Data	Maximum Error/m			RMS/m			RMS/GSD		
	X	Y	Z	X	Y	Z	X	Y	Z
DataA	0.395	-0.423	-0.815	0.235	0.200	0.408	3.917	3.333	6.800
DataB	-0.518	0.732	-1.261	0.290	0.309	0.527	2.901	3.090	5.274
DataC	-1.463	1.910	-4.331	0.814	0.764	1.258	2.714	2.545	4.194

Table 2. Direct Positioning Results for ADS40 DataUsing Updated Camera Files

camera file	DataA（RMS/m）			DataB（RMS/m）			DataC（RMS/m）		
	X	Y	Z	X	Y	Z	X	Y	Z
Cam0	0.235	0.200	0.408	0.290	0.309	0.527	0.814	0.764	1.258
CamA	0.169	0.126	0.135	0.164	0.246	0.212	0.253	0.360	0.719
CamB	0.164	0.112	0.140	0.153	0.249	0.199	0.261	0.333	0.690

Table 3. Comparison on Direct Positioning Accutacy Using Different Camera Files

	AX	AY	AZ	BX	BY	BZ	CX	CY	CZ
cam0	3.917	3.333	6.8	2.901	3.09	5.274	2.714	2.545	4.194
camA	2.817	2.1	2.251	1.641	2.46	2.121	0.843	1.201	2.397
camB	2.733	1.867	2.334	1.531	2.49	1.991	0.87	1.11	2.301

4.3 Analysis on Experimental Results

1) It can be seen from Table 1,that although the direct positioning based on POS data can reach certain precision level for ADS40 image, but there still exists from a wide gap towards pixel-level accuracy. If evaluated in absolute accuracy, the accuracy of DataA was the best, the RMS errors on checkpoints were 0.235m, 0.200m and 0.408m respectively in X, Y and Z directions, followed by DataB and DataC in descending order. It shows that under normal circumstances, the direct positioning accuracy of ADS40 images positioning accuracy declined with the ground resolution. But if the evaluation standard was changed to GSD, the situation was opposite. DataC in the worst absolute accuracy was the highest, with 2.714, 2.545 and 4.194 GSD accuracy in X, Y, and Z direction. And DataA had the lowest accuracy in three-axis direction, respectively 3.917, 3.333 and 6.800 GSD.

2) From Table 1, it can be overall seen that the direct positioning accuracy for ADS40 images was relatively close in planar X, Y direction, ranging between about 2 to 4 GSD. It was much better than that in the Z direction from 4 to 7 GSD. Three groups of data had roughly the same changing trend in the three-axis directions and it presented the obvious system errors in direct positioning.

3) It can be seen from Table 2 that for three sets of test data, the accuracy of direct positioning using camA and camB was far superior to that using cam0, which validated that the updated camera file can

significantly improve the positioning accuracy. As it was seen from Table 3, better optimization results were achieved using CamA and CamB, and the enhanced extent were roughly equal. For both situations, the accuracy improvements were closer in the planar X, Y direction, at 1.3 GSD averagely, while the accuracy improvements were most obvious in Z direction with maximum value of 4.5 GSD and a minimum of 1.8 GSD. Accuracy curve corresponding to Cam0 undulated greatly, while those of CamA and CamB were relatively flat. And the two latter curves were very similar and relatively smooth, indicating that the direct positioning of ADS40 image has been basically stable.

5. Conclusions

Three sets of ADS40 data over Songshan field were taken to conduct onboard POS assisted three-line CCD image direct positioning test and precision optimization experiments. Experimental results show that when using the original camera files, direct positioning accuracy for ADS40 data can achieve 2 to 4 GSD in planar direction and 4 to 7 GSD in height direction without ground control, which lies a certain gap with the expected accuracy. Two sets of ADS40 data were selected for self-calibration bundle block adjustment through a reasonable set of camera error model. After self-calibration, the new camera files are updated. Using the newly generated camera files, the direct positioning accuracy were significantly improved for three groups of data, the accuracy enhancement in planar direction was 1.3 GSD averagely, and that in the elevation direction was about 3.1 GSD. The optimization effect is very obvious. Experimental results demonstrates the proposed method is feasible and effective, and has significantly implications for aerial work production.

The CDMA Spread-Spectrum Cell Mobile Communication Uplink System With Cooperative Diversity

Hancheng Liao

School of Software and Communication Engineering

Jiangxi University of Finance and Economics

Nanchang, China, 330013

Liaoemail@163.com

Keywords: Cooperative Diversity, CDMA, Uplink

Abstract. In this paper, physical layer cooperative communication of code division multiple access system is explored. Many mobile terminals relay signals for each other so as to achieve spatial diversity. The cooperative scheme of the mobile terminal is well designed. The uplink system model, as well as the receiving structure is given. The performance advantage of such system is clearly indicated through simulation.

Introduction

Code division multiple access (CDMA) system is famous for combating multipath fading in wireless communication [1-2]. Large-area-synchronized (LAS) codes are very suitable to act as the multiple access codes (MACs) due to their good auto-correlation property and cross-correlation property [3-4]. Cooperative diversity is a cooperative multiple antenna technique for improving performance or channel capacities which exploits user diversity by decoding the combined signal of the relayed signal and the direct signal in wireless networks [5]. A conventional single hop system uses direct transmission where a receiver decodes the information only based on the direct signal while regarding the relayed signal as interference, whereas the cooperative diversity considers the other signal as contribution. Hence, it can be seen that cooperative diversity is an antenna diversity that uses distributed antennas belonging to each node in a wireless network. In the discussion behind, cooperative diversity is applied to uplink CDMA system.

System Model

Usually, there are many antennas which can be installed on the base station (BS) for a practical CDMA mobile communication system, while only one antenna can be installed on each mobile terminal (MT) in view of the size. For simplicity, we suppose that the number of antenna in the mobile terminal and in the base station is both only one. Although both transmitting operation and receiving operation can make use of the same antenna by time-division duplex (TDD), we can assume that two antennas are mounted—one is focusing on transmitting data and the other is focusing on receiving data. Considering that all of the constellation points are in the unit circle, phase-shift-keying (PSK) is chosen as the modulation scheme. Furthermore, we take it for grant that perfect power control technology is implemented to completely eliminate the near-far effect in all cells. As for the multiple access codes, LAS codes are employed. In addition, it is a relay technology in nature when we refer to cooperative diversity. Hereafter, the uplink CDMA system model of LAS spread-spectrum cell mobile communication system applying cooperative diversity technology is studied, as well as some simplified cooperative protocol.

In this paper, we only talk about a single cell. Naturally, there are many active mobile terminals in each cell for such mobile system. Suppose that the base station has chosen K mobile terminals as a group for some short period by a given rule—being in near area, having similar angle-of-arrival (AOA), indicating the same distance to the base station. During such period, they are cooperators, that is to say, every one of them is be in duty bound to relay the data from the others. We only discuss the

situation that the relay number of times is one and the links with twice relays are not taken into consideration. Such cooperative CDMA cell is illustrated in Fig. 1. In this situation, one base station is placed in the center and one omnidirectional antenna is installed on it.

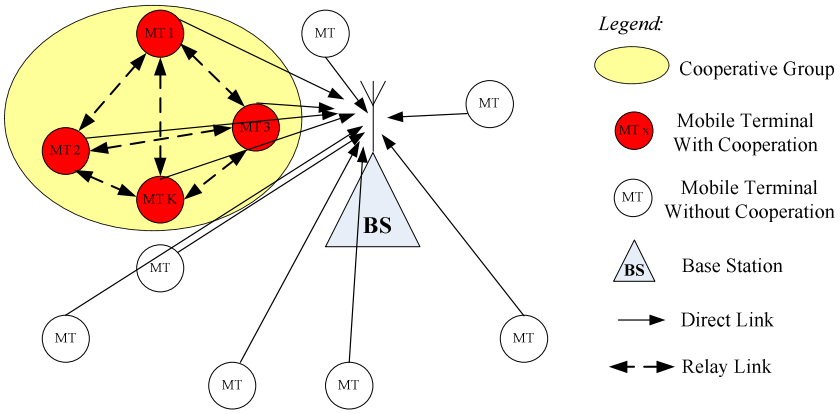

Figure 1. A cooperative CDMA cell with one base station and many mobile terminals

As we know, every each mobile terminal can acquire the spread-spectrum sequence or MAC for each other from the base station. Here, we begin with only one group consisting of K members and each member has stored K MACs from the beginning of cooperation. Other cases of many groups in a cell with either equal or different number of members in a group can be studied in further work. Also, we don't take such situation into account that any cooperative mobile terminal is working irregularly, no matter because of power cutting, interrupt or breakdown. The allocation scheme of time slots (TSs) in such cooperative uplink system is shown in Fig. 2. During the first K time slots, each mobile terminal transmits its data successively, e.g., No. k mobile terminal (named MT k) sends at No. k time slot (named TS k). Meanwhile, the other K-1 mobile terminals and the base station are receiving such data. Then it is followed by K-1 relay time slots, in which each one mobile terminal transmit data of the others by a given order. As shown in Fig. 2, the data of the first mobile terminal is transmitted by MT K in TS K+1, by MT K-1 in TS K+2, up to by MT 2 in TS 2K-1. Although there are more time slots than systems without cooperation, the communication efficiency is not reduced obviously in general according to the fact that a lot of mobile terminals have spare time in many kinds of business or even they are in standby mode.

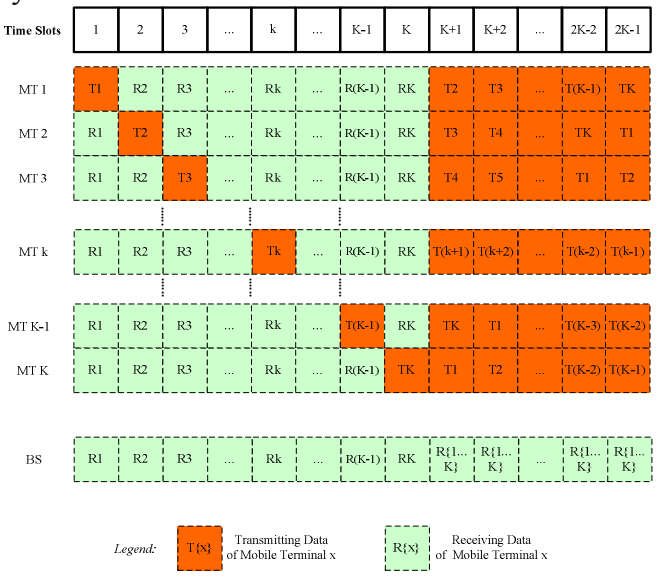

Figure 2. The allocation scheme of time slots in uplink system for K cooperative mobile terminals and one base station

Then we go on to the system model of any mobile terminal. Without loss of generality, we can only research the first mobile terminal. Its model is given in Fig. 3, where only baseband signals and

operations are mentioned. The transmitting and receiving signal of MT x is notated as $s_x(t)$ and $r_x(t)$. During the first time slot (named TS 1), MT 1 transmits its data. During the next K-1 time slots, MT 1 receives data from MT 2 to MT K in turn. In the figure, $\hat{s}_p^n$ represents the despread symbol of MT n received by MT p using MAC c_n, it is an estimate of symbol s_n^n for MT n and should be transmitted by MT p hereafter. The amplifying coefficient can be simplified as $a_p^n = 1/\left\|\hat{s}_p^n\right\|$ when PSK is employed. During the last K-1 time slots, the relay signals $a_p^n \hat{s}_p^n$ is spread with c_p and transmitted by MT p separately.

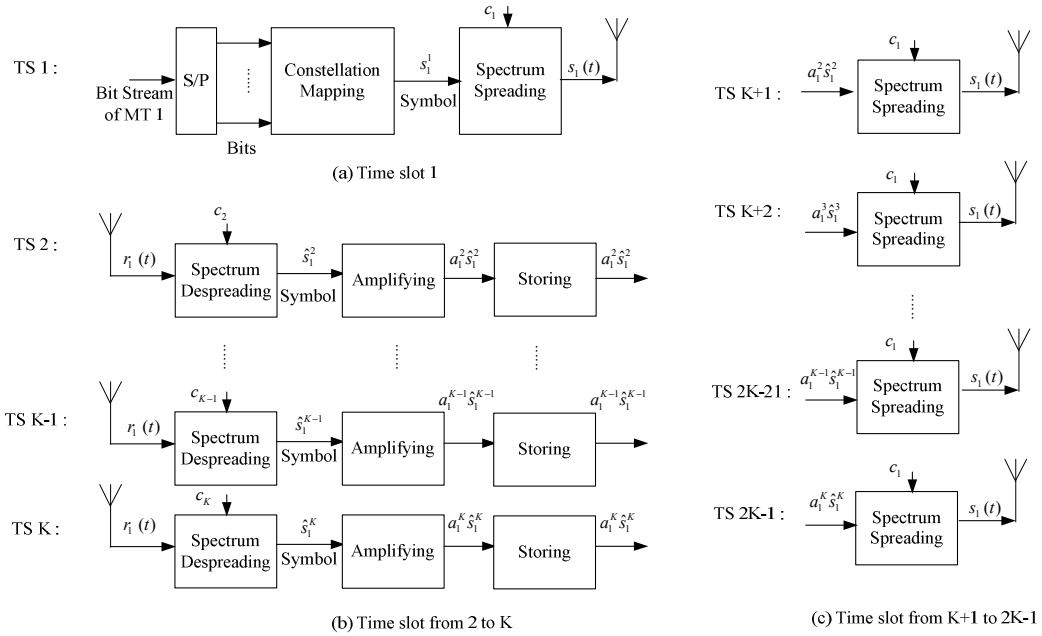

Figure 3. The uplink system model for the first cooperative mobile terminal (MT 1)

The corresponding uplink system model of base station is given in Fig. 4, where $r(t)$ is the received signal and r_j^n is the despread symbol for MT n using MAC c_n during TS j. r_{K+1}^1, r_{K+2}^1, …, r_{2K-1}^1 and r_1^1 are prepared for the next diversity combining operation. As the modulation type is PSK, we can choose equal gain combining (EGC) method and let $r^1 = \overline{r}/\left\|\overline{r}\right\|$, where $\overline{r} = (r_1^1 + r_{K+1}^1 + \cdots + r_{2K-1}^1)/K$.

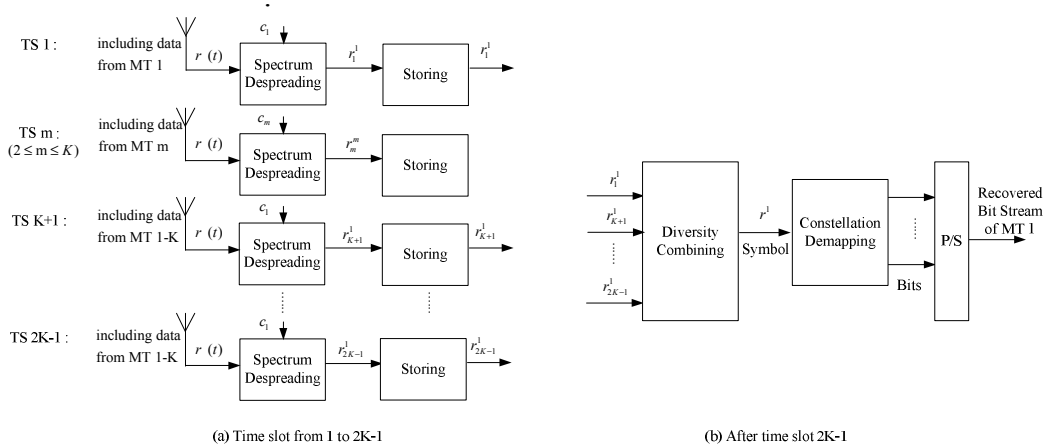

Figure 4. The uplink system model for the base station (only showing the operation concerning MT 1)

Performance Simulation

In the simulation, both system with cooperation (K>1) and system without cooperation (K=1) are considered. The spread factor is 16 and modulation type is QPSK. The channel model is ITU-VA 120 km/h. The base station knows the channel state information (CSI) but the mobile terminals don't. The bit error rate (BER) performance is simulated by MT 1 and is shown in Fig. 5. The diversity gain is obvious and almost linear to K.

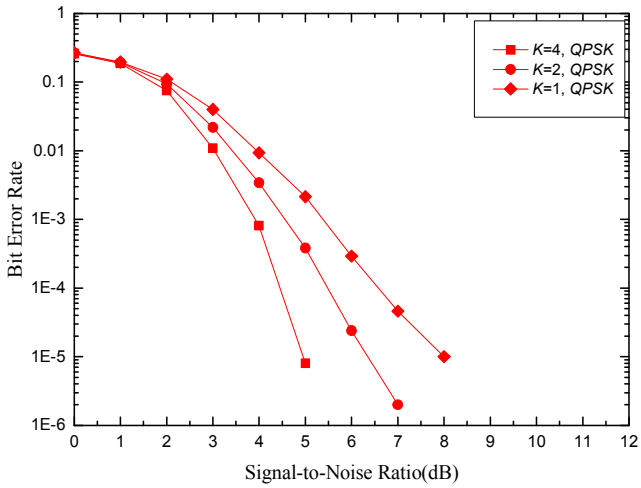

Figure 5. The BER performance of cooperative CDMA system

Summary

By applying cooperative diversity technology to existing CDMA spread-spectrum system, the system performance and capacity can be much better. As the number of cooperative users increases, the diversity gain augments. Our numerical simulation reveals that the cooperative scheme is able to extract the full distributed spatial diversity in the uplink. Of course, there is trade-off between the diversity gain and the loss of other wireless resource such as time and power resources because they are wasted to relay the signal from the source node to the destination node. Therefore, it is noteworthy that the number of cooperative users is limited.

3D Facial Shape Reconstruction From A Single Frontal Image

Qian Ma

Wuhan University of Science and Technology City College, Wuhan, China

icey_mq@163.com

Keywords: Shape from shading; Improved Fast Marching Method; Shape reconstruction

Abstract. In this paper, we propose an improved method for reconstruct 3D facial shape from a single frontal image. We use improved fast marching method to solve the Eikonal equation which can obtained from the method of shape from shading (SFS). In order to overcome the concave-convex ambiguity problems inherent to SFS, we find out the concave region and recover concave into the convex keeping the relative shape invariant to reconstruct the accuracy facial shape.

Introduction

The 3D shape recovery is a classical problem in computer vision. It recovers the relative height of each point to gets the 3D model through one or more gray images. Horn put forward the shape from shading (SFS) in the 70's [1]. He used a first order nonlinear partial differential equations (PDE) to express this problem. This equation is called the image irradiance equation. As we all know, the unique solution cannot be solved in the classical sense by SFS method. Actually, one gray image cannot avoid convex-concave ambiguities, because the singularity may correspond to the maximum value point (convex point) or the minimum point (concave point) or saddle point on the surface of the object. Thus how to avoid convex-concave ambiguities is the focus of current research.

Along with the rapid development of computer image technology, 3D face modeling and animation is applied so widely, that it has become a research focus of many scholars at home and abroad. Due to the less condition of the single view modeling, there is a great prospect of application. In this paper, we used a single frontal face image to reconstruct 3D facial shape. We transformed the image irradiance equation into the corresponding static Hamilton-Jacobi equation through the SFS method, then used the improved fast marching method to obtain the viscosity solution and it is a unique solution [2-3]. But it could only eliminate the ambiguity of saddle point [4], so we searched the concave areas which are convex actually, and recovered the accuracy facial shape by reflection.

Shape from Shading

We suppose the reflection model is a Lambert reflection model [5], in which the illuminant is located far enough from the surface, the imaging is the orthogonal projection and the albedo is constant and equal to 1. So the brightness of the image points on an object surface only decided by the cosine of the angle of incident light. The camera coordinate system is used as the reference system, and the surface is expressed as a function of $z=z(x, y)$. I is the normalized image brightness, $N = (N_x, N_y, N_z)$ is the unit normal vector of the surface, and $L = (L_x, L_y, L_z)$ is the illuminant direction. Thus we can have

$$I = N \cdot L \tag{1}$$

Consider the light source is vertical incidence, so $L= (0, 0, 1)$, and we can obtain the unit normal vector from the surface function as $n=(z_x, z_y, z_z)$, where $z_x = \frac{\partial z(x,y)}{\partial x}$ $z_y = \frac{\partial z(x,y)}{\partial y}$, $z_z = 1$. Then Eq.1 can be rewritten as

$$I = \frac{1}{\sqrt{z_x^2 + z_y^2 + 1}} \tag{2}$$

because $\nabla z(x,y)=(z_x,z_y)$, then

$$\left\|\nabla z(x,y)\right\|=\sqrt{\frac{1}{I(x,y)^2}-1} \tag{3}$$

This is a static Hamilton-Jacobi equation, also known as Eikonal equation.

Improved Fast Marching Method

The level set method was first proposed by Sethian and Osher in 1988[6], which is an efficient numerical algorithm to solve the partial differential equations. Eq.3 could be rewritten as:

$$\left\|\nabla z(x,y)\right\|=f(x,y) \tag{4}$$

Then the numerical algorithm of the level set arrival time method is:

$$\{[\max(D_x^- z_{ij},-D_x^+ z_{ij},0)]^2+[\max(D_y^- z_{ij},-D_y^+ z_{ij},0)]^2\}^{1/2}=f_{ij} \qquad i=1,...,N,\ j=1,...M \tag{5}$$

Its computational complexity is $O(N^3)$, in order to reduce the complexity, a fast algorithm has bee n developed, called "Fast Marching Method(FMM)". The basic idea of FMM is used the unidirectio nal movement of the curve in the arrival time method, creating an activated narrow-band around the transmission boundary. The arrival time of the inner points of the narrow-band is unknown, and the t ransmission boundary is one-way spread outward, like the spread of the water. When the point has b een spread, we froze the time of arrival in before, then created a new narrow-band with the recent wa ve. So we can gain the arrival time of each point finally. The computational complexity of the FMM is $O(N^2\log N)$.

The FMM used the first difference to approximately calculate the gradient ∇T. In order to improve the accuracy, we used the second order difference to approximately calculate the gradient whenever points are available, and reverted to a first-order approximation in the other cases. If we want to calculate the arrival time of the point (i,j), we need its neighbors as following: $(i\text{-}2,j)$, $(i\text{-}1,j)$, $(i,j\text{-}1)$, $(i,j\text{-}2)$.

The improved fast marching method used the second order difference to calculate the gradient if it meets one of the following two cases:

(1)The arrival time of the points which are two points away from (i,j) in each direction is known. For example, $z_{i-2,j}$ and $z_{i+2,j}$ must be known in the direction of x;

(2) The points which are two points away from (i,j) in each direction must have less arrival time than those points at one point away from (i,j). For example, in the direction of x, we must have $z_{i-2,j}\le z_{i-1,j}$ and $z_{i+2,j}\le z_{i+1,j}$.

Two order forward difference and the backward difference formula are as follows:

$$\begin{aligned} D_x^- z_{ij}&=\frac{3z_{i,j}-4z_{i-1,j}+z_{i-2,j}}{2\Delta x}, D_y^- z_{ij}=\frac{3z_{i,j}-4z_{i,j-1}+z_{i,j-2}}{2\Delta y}\\ D_x^+ z_{ij}&=-\frac{3z_{i,j}-4z_{i+1,j}+z_{i+2,j}}{2\Delta x}, D_y^+ z_{ij}=-\frac{3z_{i,j}-4z_{i,j+1}+z_{i,j+2}}{2\Delta y}\end{aligned} \tag{5}$$

By substituting the above formula into Eq.4, we can have

$$\begin{aligned}&[\max(\frac{3z_{i,j}-4z_{i-1,j}+z_{i-2,j}}{2\Delta x},\frac{3z_{i,j}-4z_{i+1,j}+z_{i+2,j}}{2\Delta x},0)]^2+\\ &[\max(\frac{3z_{i,j}-4z_{i,j-1}+z_{i,j-2}}{2\Delta y},\frac{3z_{i,j}-4z_{i,j+1}+z_{i,j+2}}{2\Delta y},0)]^2=f_{ij}^2\end{aligned} \tag{6}$$

It can be rewritten as:

$$\begin{aligned}&[\max(\frac{3z_{i,j}-\min(4z_{i-1,j}-z_{i-2,j},4z_{i+1,j}-z_{i+2,j})}{2\Delta x},0)]^2+\\ &[\max(\frac{3z_{i,j}-\min(4z_{i,j-1}-z_{i.j-2},4z_{i,j+1}-z_{i,j+2})}{2\Delta y},0)]^2=f_{ij}^2\end{aligned} \tag{7}$$

Let

$$Z = z_{i,j}, Z_1 = \min(4z_{i-1,j} - z_{i-2,j}, 4z_{i+1,j} - z_{i+2,j}), Z_2 = \min(4z_{i,j-1} - z_{i,j-2}, 4z_{i,j+1} - z_{i,j+2})$$

Then

$$[\max(\frac{3Z - Z_1}{2\Delta x}, 0)]^2 + [\max(\frac{3Z - Z_2}{2\Delta y}, 0)]^2 = f_{ij}^2 \tag{8}$$

Because the improved fast marching method guarantees the Z is larger than its neighbors Z_1 and Z_2. So we get

$$(\frac{3Z - Z_1}{2\Delta x})^2 + (\frac{3Z - Z_2}{2\Delta y})^2 = f_{ij}^2 \tag{9}$$

This equation can be simplified as follow:

$$aZ^2 + bZ + c = 0 \tag{10}$$

The coefficients are given as follow:

$$a = \frac{9}{4}(\frac{1}{\Delta^2 x} + \frac{1}{\Delta^2 y}), b = -\frac{3}{2}(\frac{Z_1}{\Delta^2 x} + \frac{Z_2}{\Delta^2 y}), c = \frac{1}{4}(\frac{Z_1^2}{\Delta^2 x} + \frac{Z_2^2}{\Delta^2 y}) - f_{ij}^2$$

The solution of equation is given as follow:

(1) If $Z<min(Z_1, Z_2)$, then the gradient component z_x and z_y are zero, so $Z^{(n+1)}=Z^{(n)}$;

(2) If $Z_1>Z>Z_2$, then $z_x \approx 0$, $z_y \approx Z^{(n+1)} - Z_2$, so $Z^{(n+1)}= Z_2+f_{ij}$;

(3) If $Z_2>Z>Z_1$, then $z_y \approx 0$, $z_x \approx Z^{(n+1)} - Z_1$, so $Z^{(n+1)}= Z_1+f_{ij}$;

(4) If $Z>\max(Z_1, Z_2)$, then solve equation: $(\frac{3Z - Z_1}{2})^2 + (\frac{3Z - Z_2}{2})^2 = f_{ij}^2$, so

$Z^{(n+1)}=\frac{Z_1 + Z_2 + \sqrt{8f_{ij}^2 - (Z_1 - Z_2)^2}}{6}$.

The experimental results are shown in Fig.1

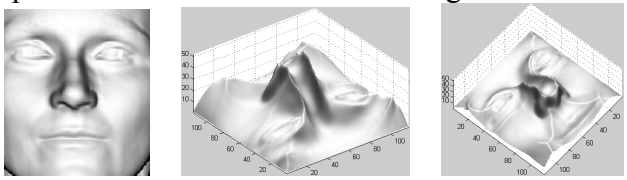

Fig.1

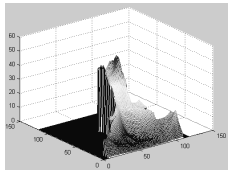

Fig.2

3D Facial Shape Reconstruction

As we can see in the experimental result, the integrity of the face shape is relatively good, but it cannot avoid convex-concave ambiguities. So we need the subsequent processing in order to get an accurate 3D face model.

We found out the recessed region firstly. Because the highest point of the nose is the lowest one in the recessed region at present, we got the initial curve which has the highest point of the nose in the vertical direction. According to the symmetry of the face, we extended each point to the horizontal direction on the curve. Then we putted the points into the concave point set which have the higher value of the height than the initial points, and updated the points and kept extend until the height decrease. The result of the recessed region which we found through the above steps is shown in Fig.2.

Then we reconstructed the recessed region keeping the relative shape invariant. Based on the boundary of the recessed region as a benchmark, we used mirroring to create convex surface so it can keep the relative shape invariant. The result is shown in Fig.3.

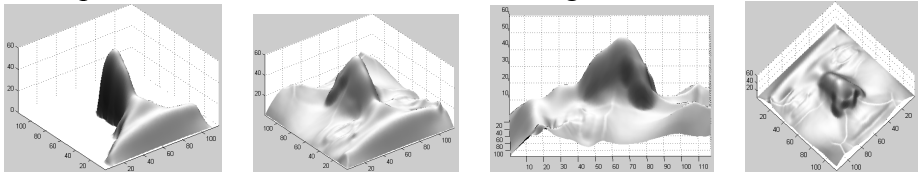

Fig.3

Experiments and Conclusions

We have performed extensive experiments on several facial images, and show a part of our results in Fig.1, Fig.2, Fig.3 and Fig.4. When the improved fast marching method to solve the SFS is used, it can recover the 3D model with integrity, but it cannot avoid convex-concave ambiguities. We can see this result from Fig.1. Then we used the proposed method in previous section to extracted concave region, we can see that the depression areas extraction are ideal from the experimental results from Fig.2. Based on the boundary of the recessed region which we found, we got the 3D face reconstruction which is shown in the Fig.3 and Fig.4. It can be seen from the results that the concave recovered into the convex keeping the relative shape invariant.

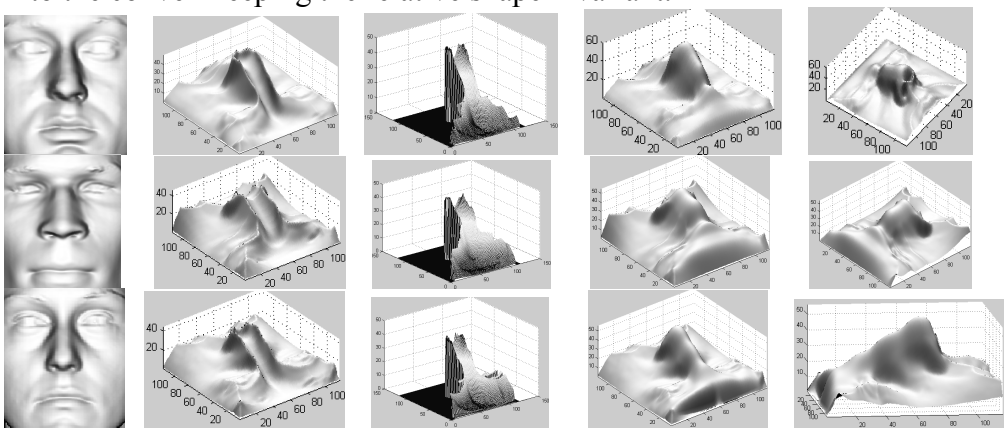

Fig.4

In this paper, we have introduced a framework to recover the 3D facial shape from a single image. We used the improved fast marching method to solve image irradiation equation based on the evolutionary algorithm, and reconstructed the concave into the convex. Experimental results have shown that our method is feasible and effective, and we can get a 3D face model which has high similarity with the original 2D image. However, much more work remains to be done in the future, for example, to consider if the light environment is more complex, and if the 2D facial image is not frontal.

Abstract. With combining Unmanned Aerial Vehicle (UAV) and the high-precision of the low altitude Remote Sensing (RS) technology, UAV RS technology has become an important complement for satellite and manned aircraft RS, so it has drawn great attention of people at home and abroad. Most of UAV RS image technologies use small digital cameras to shoot so that it causes some problems such as lower magnitude, more and larger morphing image. The image processing and mosaicing system of UAV RS implements the function of image identifying, selection of image group control points, geometric correction, mosaicing, seam lines eliminating automatically and rapidly with Interactive Data Language (IDL), and is targeted to solve the practical application problems such as preprocessing, mosaicing, seam-lines removing of civil UAV RS image.

Introduction

At present, the study on UAV RS applications has become a craze at home and abroad, many scholars and scientific research institutes have done many beneficial explorations in this area [1,2], but most of UAV RS image mosaicing technology use the traditional processing method such as ERDAS, ENVI which are targeted to process images of satellite and manned aircraft RS [3]. Therefore, there is no system that processes and mosaic civil UAV RS image because of their characteristics. Most of UAV RS image technologies use small digital cameras to shoot so that it causes some problems, for example, lower magnitude, more and larger morphing image, etc. It needs longer time to process images and the efficiency has become a bottleneck leading to restrict the development and the application of civil UAV RS field. As a result, in geometric correction of image it should take into account these factors such as characteristics of RS images, parameters of camera calibration, attitude parameter when shooting and relative geometric model. In addition, a corresponding system needs to be developed to implement interactive processing with functions of image identifying automatically and mosaicing rapidly, meanwhile, to meet the request of real-time and rapidity in image processing of civil UAV [4].

Our system focuses on solving the problems such as image preprocessing, image mosaicing and seam-line eliminating automatically and rapidly, to satisfy the needs of present practical applications.

System Research and Design

According to the need of civil UAV RS image processing, our system has the following functions: (1) Image import, including import the description of image such as name, storage path and size. (2) Extract the feature points of a single image and match the feature points of two adjacent images. (3) Mosaic images automatically with obtaining feature points. (4) Selecting group control points for geometric correction of image. (5) Mosaic image interactively after geometric correction.

As to original data of UAV RS image, synchronizing and correcting camera interior error and exterior orientation attitude parameters of images in data reception department, the corrected images do further corrective processing by selecting character points and geometric precision correction.

Then, after mosaicing images, systematic eliminating seam-lines between two adjacent images, crop images and does other processes. The system processing procedure is shown as Fig. 1.

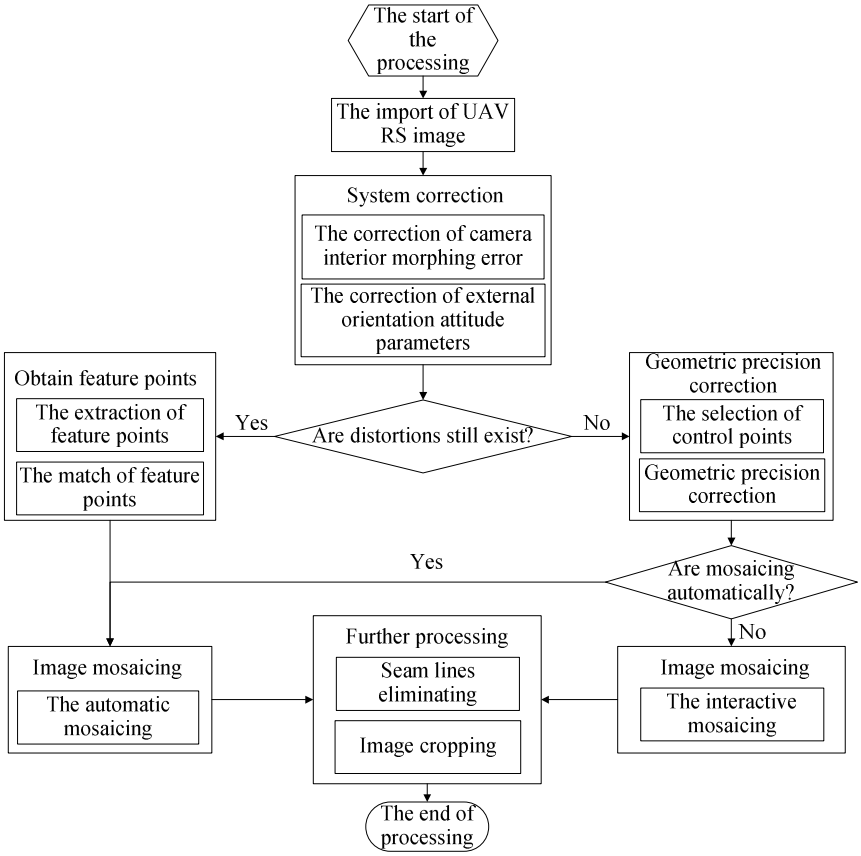

Fig.1 The system processing procedure.

Selecting control points is the first step for interactive correction and mosaicing of image. Its' quantity and quality affect corrective accuracy of image directly, as well as the geometric accuracy of mosaicing finally. The selecting procedure of control points is shown as Fig. 2: At first, the system display images with callout window; then enlarge the part of image at zoom window through clicking any area of callout window; at last locate control point accurately in zoom window.

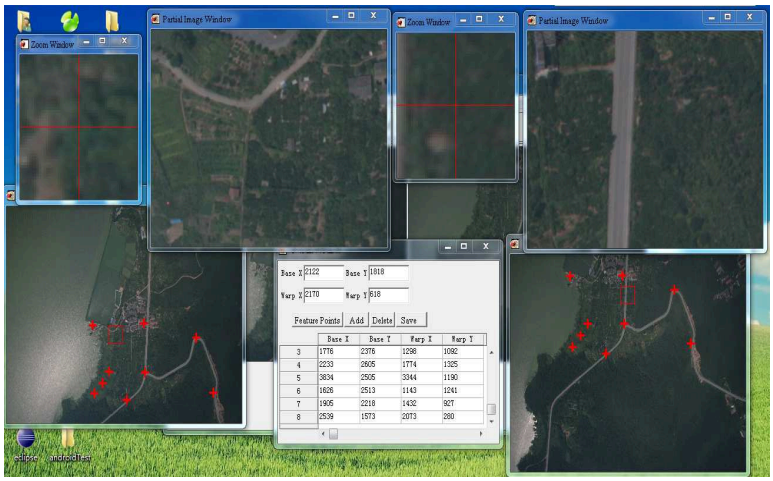

Fig.2 The window of control point selection.

After selecting a couple of control points, their coordinates are added into the control point list of the main window and are marked in the corresponding location of the marking window. The locations marked by the red crosses in Fig. 2 are control points selected. Click the preserving button of the main

window to preserve them when more enough and evenly distributed control points are selected. As The file format of preserving control points' coordinates can be saved by TXT text format as Fig. 3.

Fig. 3 The preserving file of control points.

Before correcting the two images interactively, select the control point file and then set the corresponding correction parameters, which include correction, polynomial and resampling methods, as shown in Fig. 4.

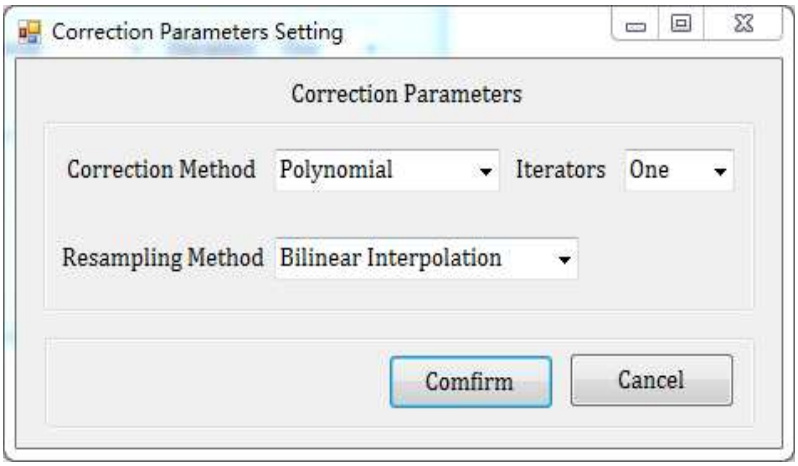

Fig. 4 The window of setting correction parameters.

The interactive mosaic of image is based on the mosaic of image pixels, is like that find the best mosaic location of the two images by moving them. And then according to the location of the image, construct a new array and assign values to finally preserve it [5]. The image with geometric precision correction can mosaic directly with the reference image. Our system adopted the strategy to mosaic the feature points automatically as follow: obtaining the corresponding relationship of the two images by using the polynomial model and then correct the reference image.

First of all, according to the corrected image, obtain the corresponding coordinates of its image pixels which are in its four angles. Then, obtain a region of covering the reference image and a minimal rectangle of the corresponding correction region as a new image to save. Next, ascertain the gray value of each image pixel in the new image.

The image pixels of the mosaic image are divided into four regions: the first kind of pixel point is belong to neither the reference image nor the correction image, called the background point; the second kind of pixel point is only belong to the reference image, called the reference image point; the third kind of pixel point is not only the reference image but also belong to the correction image, called the overlapping point; the forth kind of pixel point is only belong to the correction point, called the correction image point. The characteristics of these four regions' pixel points are different, so adopt different strategy to set gray value. For the background point, its pixel value is assigned to black. For

the reference image point, its pixel value is unchanged. For the overlapping point, its pixel value is replaced with pixel value of the reference image because of the geometric errors may be existed in the two image. For the correction image point, its pixel value is assigned to gray value of the correction image. Ensure the best mosaic location of the two images by moving their locations. At last, according to its location, select the start point and the end point of the seam-line and feather width. And then mosaic and feather the given area with compulsory improved algorithm provided by us [5]. Fig. 5 shows the effects after image mosaicing and feathering.

Fig.5 The effects after image mosaicing and feathering.

Summary

This system implements selection of image group control points, geometric correction, mosaicing, se- am lines eliminating and other functions with Interactive Data Language (IDL). It has been applied in Nanjing Meteorological Administration in China, and has already got the software copyright certific- ate authorized by Copyright Protection Center of China. It is targeted to solve the practical application problems such as preprocessing, mosaicing, seam-lines removing of civil UAV RS image.

Keywords: Image Retrieval, Saliency Map, Color Histogram

Abstract. With the development of the internet, more and more images appear in the internet. How to effectively retrieve the desired image is still an important problem. In the past, traditional color histogram is used image retrieval system, but color histograms lack spatial information and are sensitive to intensity variation, color distortion and cropping. As a result, images with similar histograms may have totally different semantics. So the spatial information should be included in color histogram. The color histogram based on saliency map approach is introduced to overcome the above limitations. In this paper, we present a robust image retrieval based on color histogram of saliency map. Firstly, in order to extract useful spatial information of each pixel, the steady saliency map of the images is extracted. Then, color histogram based on saliency map is introduced, and the similarity between color images is computed by using the color histogram of saliency map. Experimental results show that the proposed color image retrieval is more accurate and efficient in retrieving the user-interested images.

Introduction

With the development of Internet, there is an explosive growth of color image databases. How to search through such a large scale collection effectively and efficiently is still a challenging task in computer vision [1] [2] [3]. The increasing number of images has opened the need for developing powerful tools for searching through such image databases. Automatic retrieval of an image from a whole data set using representative text-annotation comes from the early 1970s.However; manual indexing and annotation can be highly subjective, inefficient and tedious. Content based image retrieval (CBIR) techniques overcome these difficulties by making use of image-based features and attributes.So CBIR gets more and more attentions in nowadays [4].CBIR system relies on visual feature-based representations, such as color, texture, shape, etc., which can be extracted from images automatically. In these features, the most important feature is color because color is the most intuitionistic feature of a image, and it is robust to background complication and is independent of image size and orientation. Considerable research has been carried out on the basis of color content. The most popular representation of color information is global histogram. Statistically, it denotes the joint probability of intensities of the three-color channels, thus describing the global color distribution in an image. In general, the color histogram provides useful clues for the subsequent expression of similarity between images, due to its robustness to background complications and object distortion. Moreover, it is translation, scale, and rotation invariant, very simple to implement and systems encountering histograms exhibit a fast retrieval response that makes real-time implementation easier.

There are two main weaknesses in traditional color histogram. First, traditional color histogram doesn't take into account the spatial distribution of color across different areas of the image. The second, traditional color histogram cannot retrieve images with noise effectively [5].

To deal with the problems, a number of methods have been developed for integrating color and spatial information for content-based queries. Eauqueur [6, 7] make use of segmentation technology to obtain image's main areas in image retrieval, and then extract each area's color and spatial

information as image's features. But the image segmentation is still an open problem in computer vision so far. So these systems cannot generate extremely good performance. Wang [8] uses image's color area's spatial information and shape feature to calculate shape-matrix based histograms, but the model for similarity calculating has difference with human visual system. Ediz [9] suggests an image retrieval algorithm based on distance-orientation histogram, which calculates histograms in special distance and orientation. Jeong[10] uses Gaussian vector quantization technology to extract color histogram, but Gaussian quantization not only costs too much time but also the calculation is too complex. Wang [11] develops a method for making use of significant bit –plane, which could cut down time complexity and spatial complexity due to the low histogram's dimension.

In this paper, we propose a new color histogram based on saliency map. The saliency map, which can extract the important regions in the image, and can also separate the background and foreground. The color histogram based on saliency map is considered in the image retrieval system. The simulation experiment results have shown a significant improvement over the traditional methods.

The remainder of this paper is organized as follows: the calculation of saliency map is described in next section. And we will describe how to construct color histogram based on saliency map in Section 3. Extensive experiments results on benchmark datasets will be discussed in Section 4.We then make concluding remarks in Section 5.

The calculation of saliency map

In order to construct a novel histogram which contains spatial location information, a saliency map is combined with traditional scheme. So we should calculate the saliency map of the image [12].

2.1 Pattern distinctness

It's a common method to measure pattern distinctness based on comparing each image patch to all other image patches. If the patch is salient, it should be different from other patches. We also find the color image's non-distinct patches are mostly concentrated in the high-dimensional space, while distinct are mostly scattered. So all 9*9 patches are extracted and the average patch is computed. And then we compute the distance between each patch and the average patch and normalize by maximum distance. The average is shown as follows:

$$P_A = \frac{1}{N}\sum_{x=1}^{N} P_x \tag{1}$$

Where PA is image's average patch, p_x is image's 9*9 patch, if p_x is dissimilar to the average patch, this patch is considered salient.

In order to further improve the accuracy of measuring pattern distinctness, PCA coordinate is utilized. Thus, pattern distinctness $P(p_x)$ is defined as:

$$P(p_x) = \| \tilde{p}_x \|_1 \tag{2}$$

Where $\tilde{p}_x$ is p_x's PCA coordinate.

2.2 Color distinctness

Pattern distinctness is not sufficient for all images. So color distinctness should be used to further strengthen the extraction of salient objects. There are two steps for detecting regions of distinct color.

The first step, we utilize the SLIC superpixels to segment the image into regions. And then, we define the color distinctness of region in CIELAB color space as follows:

$$C(r_x) = \sum_{i=1}^{M} \| r_x - r_i \|_2 \tag{3}$$

Where M is the numbers of regions, r_x is the region we want to calculate and the r_i is the i-th region of M regions.

2.3The combination of pattern distinctness and color distinctness

After the steps above, we could get each patch's pattern distinctness and color distinctness. If the patch is distinct, the patch should salient both in color and pattern. So we could combine color and pattern as follows:

$$D(p_X) = P(p_x) \cdot C(p_x) \quad (4)$$

This map is normalized to the range [0, 1].

Generally speaking, the center of the image is more important than the surrounding. Because the salient object is generally located in the center of the image. So a weight map $G(p_x)$ that is weighted sum of all the Gaussians is generated. So the finally saliency map is shown as follows:

$$S(p_X) = G(p_x) \cdot D(p_x) \quad (5)$$

The calculation of color histogram based on saliency map

The traditional color histogram tells the global distribution of colors in the images. But color histogram doesn't take into account the spatial information. Adopting the saliency map could solve the problems. We don't calculate each color's distributing in the whole images any more, but in saliency map. We can eliminate useless information in the image but hold useful information. Because saliency map is important area in the image, so we could avoid the distribution of useless information. We now detail the different steps of scheme:

Step 1: calculating each color's saliency score in the image as section 2

Step 2: calculating the summation of each color's pixels' saliency score in the image

$$H(i) = \sum s(p_x) \quad (6)$$

Step 3: normalizing the vector $H(i)$ and calculating color histogram

Experiment results

To prove the capability of this paper, we give out the experimental results of our system, and compare the results with global histogram. During the experiment, we choose testing set which is used by system *SIMPLIcity* as image database. The images database are chosen form *Corel* image database, which includes 10 sorts (table 1) and which each sort has 100 images.

Table 1: Ten sorts of the image database

Class NO.	1	2	3	4	5	6	7	8	9	10
Semantic	Bus	Horse	Flower	Dinosaur	Building	Elephant	People	Beach	Scenery	Dish

To prove the validity of this paper, we choose 5 images in each sort randomly to calculate the precision and recall.

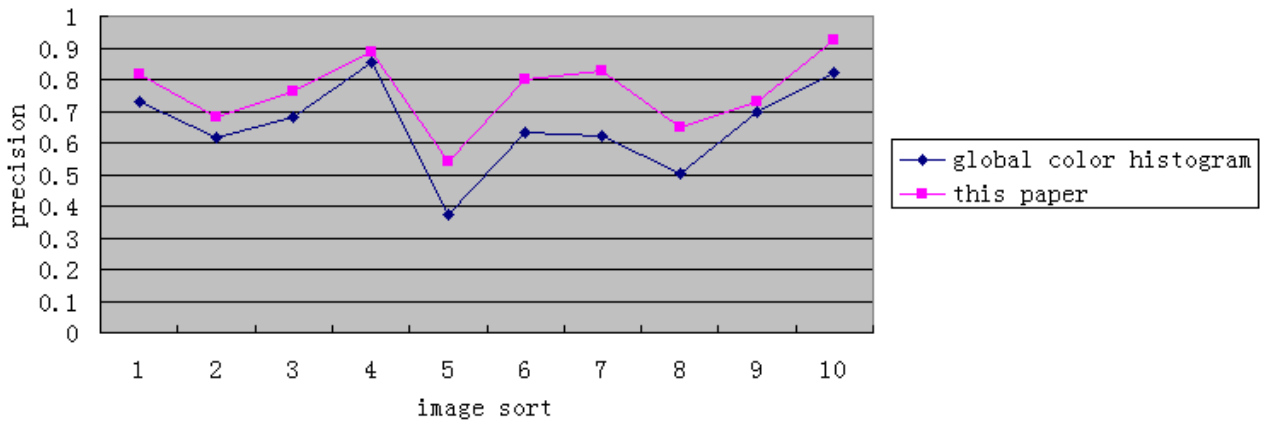

Fig1: Precision of global color histogram and this paper

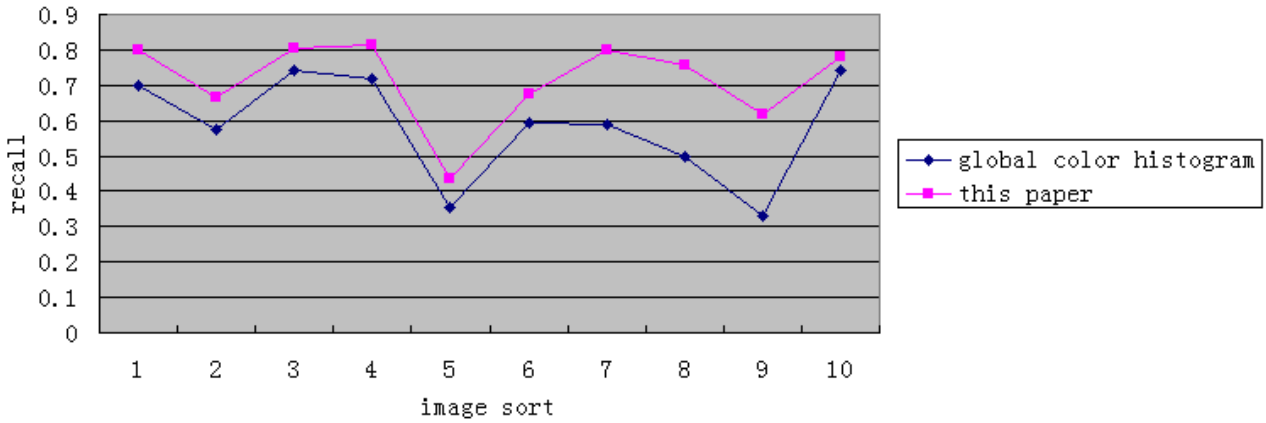

Fig2: Recall of global color histogram and this paper

Conclusion

In this paper, we propose a novel color histogram based on saliency map for image retrieval, saliency score of image is utilized to construct color histogram. In our new scheme, spatial location is contained in histogram, which can improve retrieval result. The simulation experiments show the effectiveness of our method.

Key words: Beamforming. High-speed Railway. Kerdock Codes. LTE

Abstract. Beamforming technique based the reciprocity of LTE communication system for high-speed railway is a practical way to improve the system performance in this paper. Kerdock codes, which facilitate efficient codebook and codeword search, are implemented in the LTE system for high-speed railway as the beamforming precoding codebook. The analysis of complexity and simulation results about the communication system of the beamforming with Kerdock codes (KBF) show that the proposed KBF can eliminate complex multiplications and improve the Bit Error Rate (BER) performance at large SNR compared with the existing beamfoming communication system for high-speed railway.

Introduction

With the rapid development of high-speed railway, the reliability and efficiency of wireless communication systems are facing serious challenges. The high speed mobility of onboard mobile stations brings serious Doppler Effect which reduces the performance of the existing communication systems. Recently, some of the advanced and innovative technologies of LTE can be applied to high-speed railway communication systems such as beamforming technique in [1,2]. Based on the linear topology of the high-speed communication systems base stations (eNodeBs) and the characteristic which the users and eNodeBs share the train running velocity information. Opportunistic Beamforming (OBF) [1] technology and Location information-assisted Opportunistic Beamforming (L-OBF) [2] for high-speed railway LTE system are proposed, and the L-OBF can obtain better achievable rate compared with the OBF.

In this paper, we apply Kerdock codes, whose codebook is generated by the transmitting antennas $M_t = 2^B (B \in \{1,2,\})$, as the beamforming precoding code in high-speed railway LTE system. We not only compare the storage and the search complexity between KBF and L-OBF, but also the BER performance and the achievable rate among KBF, L-OBF and OBF.

Channel Model for High Speed Railway

Linear network for high-speed railway communication is the same as in [2], each eNodeB has M_t antennas, the cell radius is R and the vertical distance from eNodeB to the track is d_{min}, the distance between the adjacent eNodeBs is L_e. Assume that there are U onboard transceivers on the train whose length is L, and then the equal space between the transceivers will be $L/(U-1)$. Every onboard transceiver, which can be viewed as a user u, is equipped with a signal antenna for communication with the eNodeBs. The distance gone through by user u is denoted by d_m, and as shown in Fig. 1, the angle of the direct path to user u's moving direction is Θ_u. Eq. 1 is the calculation of Θ_u.

$$\Theta_u = \begin{cases} arc\cot\left(\dfrac{\sqrt{R^2 - d_{\min}^2} - d_m}{d_{\min}}\right), & for \quad 0 \le d_m \le \sqrt{R^2 - d_{\min}^2} \\ \pi - arc\cot\left(\dfrac{d_m - \sqrt{R^2 - d_{\min}^2}}{d_{\min}}\right), & for \sqrt{R^2 - d_{\min}^2} < d_m \le 2\sqrt{R^2 - d_{\min}^2} \end{cases} . \quad (1)$$

Compared to the distance between the eNodeB and the user, the transmit antennas are at close proximity, and then the fading gains of the antennas are correlated [1]. The correlated Rician channel between the user u and the eNodeB's antenna n can be expressed as [3]:

$$h_{un}(t) = \sqrt{\frac{K_u}{1+K_u}} \exp(j\theta_{un}) + \sqrt{\frac{1}{1+K_u}} b_{un}(t) . \quad (2)$$

where K_u denotes the Rician factor of the physical channel from eNodeB to user u, and $b_{un}(t)$ is an independent complex Gaussian random variable with zero mean and variance one: $b_{un}(t) \sim CN(0,1)$. The angle θ_{un} is calculated as follows:

$$\theta_{un} = \frac{2\pi n d f_c \cos\Theta_u}{c} . \quad (3)$$

where the space d between two antennas is not larger than half wavelength, f_c denotes the carrier frequency, c represents the velocity of light.

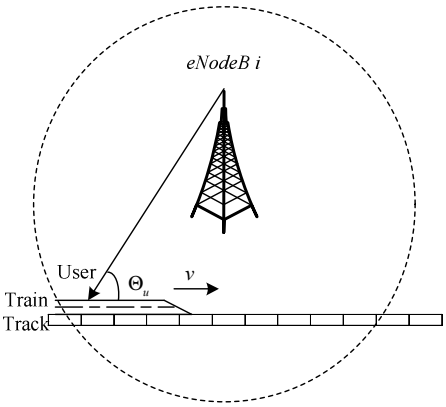

Figure 1: User *u*'s direction of arrival Θ_u

The Construction of Kerdock Codes

A brief illustration of constructing mutually unbiased bases (MUBs) for Kerdock codes was introduced in [4] and [5]. The Kerdock codes are used to generate the precoded LTE System for high-speed railway. The generated M_t+1 MUBs are $D, D^2, \ldots, D^{Mt+1} = I$. The general construction of Kerdock codebook is as follows.

1) Construct the $M_t \times M_t$ Sylveste-Hadamard matrix $H_{Mt} = H_2 \otimes H_2 \ldots (B\ times)$ by the Kronecker product of B Sylveste-Hadamard matrix $H_2 = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$.

2) Generate a $M_t \times M_t$ diagonal matrix by $\{1, -1, j, -j\}$. Then get the matrix D by the product of the diagonal generator matrix and H_{Mt}. The generated M_t+1 MUBs are $D, D^2, \ldots, D^{Mt+1} = I$.

3) Take the columns of each basis to construct the beamforming codebook $F = \{f_1 = [D]_1, f_2 = [D]_2, \cdots, f_{(M_t+1)\times M_t} = [D^{M_t+1}]_{M_t}\}$.

Beamforming Communication System with Kerdock Codes for High-speed Railway

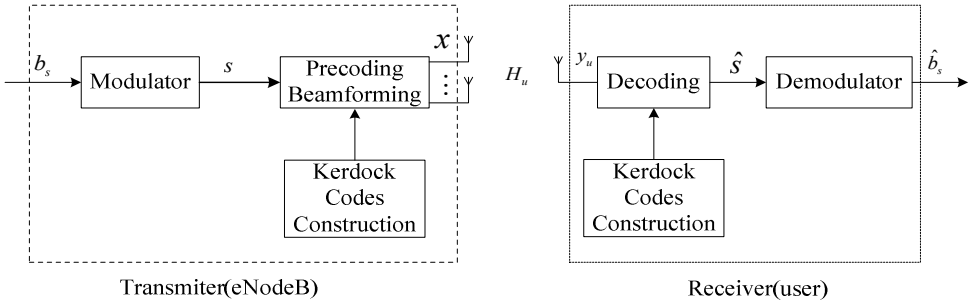

Figure 2：Beamforming with Kerdock codes communication system for high-speed railway

In the beamforming with Kerdock codes communication system for high-speed railway, let each eNodeB and user construct the beamforming Kerdock codebook $F=\{f_1,f_2,\ldots,f_N\}$. At time slot t, the eNodeBs select the user and the codewords according to the maximum ratio combining criterion such as

$$[u^*, F_u^*] = \arg \max_{\substack{u\in\{1,\cdots,U\} \\ F_i\in F}} \left| H_u F_i \right|. \tag{4}$$

The communication system model between eNodeB and the selected user is shown in Fig. 2. The i.i.d.(independent identity distributed) bit stream b_s is modulated to get $s(t)$ by MQAM modulation. The $s(t)$ is precoded to obtain the transmit signal vector $x=F_u^* s(t)$. The received signal vector of the user u is

$$y_u(t) = H_u(t)x + n_u(t). \tag{5}$$

where $H_u=[h_{u1},h_{u2},\ldots,h_{uMt}]$, and $n_u(t)$ is additive white Gaussian noise: $n_u(t)\sim CN(0,\sigma^2)$.

Then the user u get the signal by ML detection such as

$$\hat{s}(t) = \arg \min_{s(k)\in Q} \left| y_n(t) - H_u(t) F_u^* s(t) \right|. \tag{6}$$

Storage and Search Complexity

Table 1: The storage of eNodeB when M_t and U changes (N_b=8bits)

M_t	2		4	
U	8	24	8	24
KBF (bit)	64	64	96	96
L-OBF (bit)	256	768	512	1536

Storage. Assume that both the the eNodeB and the user need N_b bits to store a real number, and there are U users in the system. In [1] and [2], OBF and L-OBF need $2N_bUM_t$ bits for both the eNodeB and the user. However, KBF only needs $(4+2\times M_t)\times N_b$ bits. Compared to OBF and L-OBF, the storage of the KBF system has no relation with the number of the users.

For example, N_b = 8bits, the storage of the eNodeBs of the KBF and L-OBF system is shown in Table 1. It can be seen that the storage of the KBF is less than L-OBF.

Search Complexity. The search complexity is concerned about: I. the search of the user u by eNodeB; II. the search of the codeword F_u^* by eNodeB; III. the detection of the signal by the user u. Let the number of the users be U, the transmit antennas of the eNodeB be M_t, M-ary modulation be implemented. Multiplication and addition of complex numbers are considered in this section.

In the L-OBF system, the operation of I and II requires $M_t \times k \times U$ complex multiplications and $(M_t-1) \times k \times U$ complex additions. And for KBF system, the same operation of I and II in Eq. 4 need $UN \times (M_t-1)$ complex additions. For both L-OBF and KBF, the operation III in Eq. 5 requires the same M_t+M-1 complex additions, $M_t + M$ and M complex multiplications, respectively.

From the above comparison of KBF and L-OBF, the KBF system needs a small storage and the complexity is low at both the transmitter and the receiver.

Simulation Results

In this section, the results demonstrated below are based on Monte Carlo simulation over the channel for high speed railway. The simulation parameter settings are as follows: the antenna is omni-directional, f_c = 2GHz, K_u = 6, d_{min} = 30, R = 3km, L_e = 4.8km, transmission time interval Δt = 500ms, and the speed of the train is 360km/h. The Kerdock codebook for M_t = 4 and M_t = 2 are constructed by section 2(see in [4]).

The BER of 16QAM with Mt = 2 and Mt = 4 when U=16 is depicted in Fig. 3 and Fig. 4. It is observe that the performance of KBF system is better than L-OBF system when SNR > 12dB and SNR > 8.2dB, respectively.

$$R = E[\log_2(1+\rho F^H H^H HF)]. \tag{9}$$

The ergodic achievable rate of Mt = 2 and Mt = 4 with different number of users based on Eq. 9(ρ is the average SNR) is depicted in Fig. 5 and Fig. 6. We can see that the achievable rate of KBF system are lower than the L-OBF system, but higher than OBF system.

Conclusion

In this paper, Kerdock codes are applied as the beamforming precoding code in high-speed railway LTE system. In KBF system, the signal processing at eNodeB only needs addition operations. Although the signal detection at the user requires the same number of complex additions, the numbers of complex multiplications are less than L-OBF and OBF system. Therefore, the KBF system complexity is low, and can reduce implementation costs for signal processing. The simulation results show that the BER performance of KBF system is better than L-OBF system and OBF system at large SNR. The achievable rate of KBF system is lower than the L-OBF system, but higher than OBF system. So the beamforming with Kerdock Codes in LTE system for high-speed railway can get a tradeoff between the performance and complexity.

Keywords: image encryption, chaotic map, dynamical diffusion

Abstract. This paper designs an image encryption algorithm with a dynamical feedback operation based on sensitive chaotic system. In the proposed algorithm, the piece wise linear chaotic map is selected to construct pseudo-random keystream sequences. The pseudorandom keystream sequences are used to permute and substitute the plain image data. To enhance the complexity and security of the algorithm, each pixel is dynamically confused by its two previous adjacent encrypted pixels which are specified by a quantized binary tuple derived from a chaotic element. Both theoretical analysis and experimental tests show that the proposed algorithm is secure and efficient.

Introduction

Securing of digital image has become an important research topic in recent years. Image data have particular properties such as bulk capacity, high redundancy and high correlation among image pixels. Traditional encryption technologies regard digital image data as common data without considering their special properties, so they are not suited in protecting digital image data.

The chaotic system has interesting and close relationship with cryptography. Besides, the chaotic system has a lot significant properties which are favorable to the digital image security, such as ergodicity, aperiodicity, nonconvergency and sensitivity to initial conditions [1]. Therefore a lot of chaotic encryption methods [2-12] are investigated and employed in securing digital image data. In the literature, most of the algorithms are composed of the permutation and substitution procedures to satisfy the Shanon's confusion and diffusion criteria. In a substitution procedure, feedback operation is always adopted to resist chosen-plaintext attacks. Generally, each pixel is confused by its previous adjacent encrypted pixel, such that feedback operation has a fixed mod.

In this paper, an image encryption algorithm based on sensitive chaotic system is proposed. First the original image is permuted by an effective matrix multiplexing transform. Second, each pixel of the image is dynamically confused by a chaotic element and the two previous adjacent encrypted pixels which are specified by a quantized binary tuple derived from a chaotic element. Such a dynamically feedback operation provides high complexity. Computer simulation results and analysis are provided to demonstrate the algorithm's high level performance of security and efficiency.

PWLCM

One dimensional chaotic function, Logistic map, is widely used in cryptography applications as its high level efficiency and low computational complexity. However, it is pointed out insecure to statistical attacks. To overcome the security weakness of Logistic map, piece wise linear chaotic map (PWLCM) is adopted to generate chaotic numbers in this paper. The PWLCM is described by:

$$x(n)=F(x(n-1))=\begin{cases} x(n-1)\times\dfrac{1}{r}, & \text{if} \quad 0\le x(n-1)<r \\ (x(n-1)-r)\times\dfrac{1}{0.5-r}, & if \quad r\le x(n-1)<0.5 \\ F(1-x(n-1)), & if \quad 0.5\le x(n-1)<1 \end{cases} \tag{1}$$

where r is a control parameter of PWLCM and $x(n) \in (0,1)$ is the iteration trajectory value. When $r \in (0,0.5)$, PWLCM evolves into chaotic state. PWLCM can produce excellent pseudo-random sequences as it has uniform invariant distribution and good ergodicity. The produced pseudo-random sequences are fit to digital image cryptographic application.

The Proposed Image Encryption Algorithm

The proposed algorithm is described in this section. The algorithm includes two parts: permutation procedure and substitution procedure. They are stated in the following subsections.

3.1 Permutation Procedure

For any size ($M \times N$) of a grayscale image $I(m,n)$, The permutation procedure is described as follows:

1. Use Eq. (1) to generate two groups of pseudo-random sequences $\{x_1(i)\}_{i=0}^{M-1}$ and $\{x_2(j)\}_{j=0}^{N-1}$, with the different initial values and parameters of $(x_1(0), r_1)$ and $(x_2(0), r_2)$ respectively.

2. Sort the sequences $\{x_1(i)\}_{i=0}^{M-1}$ and $\{x_2(j)\}_{j=0}^{N-1}$ in ascending order and get two ordered sequences $\{\overline{x_1}(i)\}_{i=0}^{M-1}$ and $\{\overline{x_2}(j)\}_{j=0}^{N-1}$.

3. Find the index values of $\{\overline{x_1}(i)\}_{i=0}^{M-1}$ in $\{x_1(i)\}_{i=0}^{M-1}$ and get the index transform sequence $\{T_1(i)\}_{i=0}^{M-1}$. Get another index transform sequence $\{T_2(j)\}_{j=0}^{N-1}$ from $\{x_2(j)\}_{j=0}^{N-1}$ and $\{\overline{x_2}(j)\}_{j=0}^{N-1}$ in the same way.

4. Define permutation matrices by

$$P_1(i,j)_{M\times M} = \begin{cases} 1 & for \quad (T_1(i), i) \\ 0 & others \end{cases}, \quad P_2(i,j)_{N\times N} = \begin{cases} 1 & for \quad (j, T_2(j)) \\ 0 & others \end{cases} \tag{2}$$

Then the permutation procedure is described as an effective matrix multiplexing transform

$$P = P_1 I P_2 \tag{3}$$

The inverse transform of permutation for decryption is described by

$$I = P_1^{-1} P P_2^{-1} \tag{4}$$

3.2 Substitution Procedure

The substitution procedure is described as follows:

1. Get the permuted image $P_{M\times N}$ from the permutation procedure of Section 3.1. We treat $P_{M\times N}$ as a linear sequence in the substitution procedure.

2. Iterate the PWLCM k times with initial value and parameter $(x_3(0), r_3)$ to get rid of the harmful effect of initial value.

3. For $i = 0$ to $M \times N - 1$ perform the following steps:

(a) Compute a chaotic state value x from PWLCM.

(b) Calculate an 8-bit random value

$$d_i = \mathrm{mod}(floor(x \times 2^{16}), 256) \tag{5}$$

and a binary tuple

$$q_i = (q_i(0), q_i(1)) = \begin{cases} (0,1) & if \quad 0 \le x < s \\ (1,0) & if \quad s \le x < 2s \\ (1,1) & if \quad 2s \le x \le 1 \end{cases} \tag{6}$$

where $s \in (0,0.5)$ is a control parameter which can be served as a part of the key.

(c) Compute the current value of the cipher image by the following formula

$$C_i = P_i \oplus \mathrm{mod}(q_i(0)\times C_{i-2} + q_i(1)\times C_{i-1} + d_i, 256) \quad (7)$$

where $\oplus$ is the bit-wise exclusive OR operator. The initial constant value C_{-2} and C_{-1} are served as a part of the key too. The inverse transform of diffusion for decryption is described by

$$P_i = C_i \oplus \mathrm{mod}(q_i(0)\times C_{i-2} + q_i(1)\times C_{i-1} + d_i, 256) \quad (8)$$

The permutation procedure and substitution procedures are to satisfy the Shanon's confusion and diffusion properties respectively. In order to enhance the security, these procedures will be repeated t ($t \geq 2$) times and the final encrypted image is obtained.

3.3 Discussion

The proposed encryption algorithm has a simple structure that combines two primitive procedures. This structure provides high efficiency and simplicity for implementation.

The proposed algorithm shows high sensitivity and feedback properties. Depending on the quantized binary tuples of PLWCM, any output value C_i of the substitution procedure is a dynamical confusion obtained from its two respective previous adjacent encrypted pixels C_{i-2} and C_{i-1}. Specified by the quantized binary tuple $(q_i(0), q_i(1))$, C_{i-2} and C_{i-1} are dynamically adopted to participate in confusing the plain pixel P_i, which greatly enhances the sensitivity and security of the algorithm.

Experiment Result

For validating the proposed algorithm, original and encrypted images of Barbara and Peppers are shown in Fig. 1. The results are achieved by setting $r = 0.3$, $s = 0.4$, $k = 1000$, and $t = 2$. From the figure, no visual relationship can be found between the original and encrypted images.

Fig. 1 The original images and the encryption results

Performance Analysis

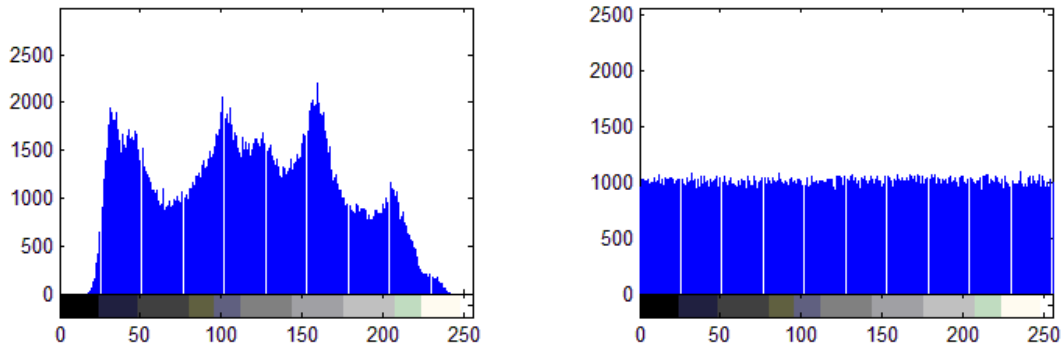
Several tests and analysis are made in this section to validate the security of the proposed algorithm.

5.1 Key Space

To provide the proposed algorithm with high security, the key space should be large enough to make any brute force attack infeasible [13]. The encryption algorithm consists of nine key parameters in this paper, they are $x_1(0)$, $x_2(0)$, $x_3(0)$, r_1, r_2, r_3, s, C_{-2} and C_{-1}, where the real numbers $x_1(0)$, $x_2(0)$, $x_3(0) \in (0,1)$, r_1, r_2, r_3, $s \in (0,0.5)$ and the integer parameters C_{-2}, $C_{-1} \in [0,255]$. If the calculation precision is 10^{-14}, the secret key space is $(10^{14})^7 (2^8)^2 \approx 2^{341}$. Clearly the key space is large enough to resist the brute force attacks.

5.2 Histogram Analysis

The histogram indicates the pixels distribution of an image. An encryption scheme is more robust against statistical attack and differential attack when the histogram of an encrypted image has a uniform distribution. Fig. 2(a) and (b) represent the histogram of plain Barbara and encrypted Barbara respectively. From the figure it is clear that the histogram of the encrypted image is completely uniform and significantly different from that of the plain image. Hence, it is not feasible to employ statistical attack or differential attack on the proposed algorithm.



(a) Histogram of plain Barbara (b) Histogram of encrypted Barbara

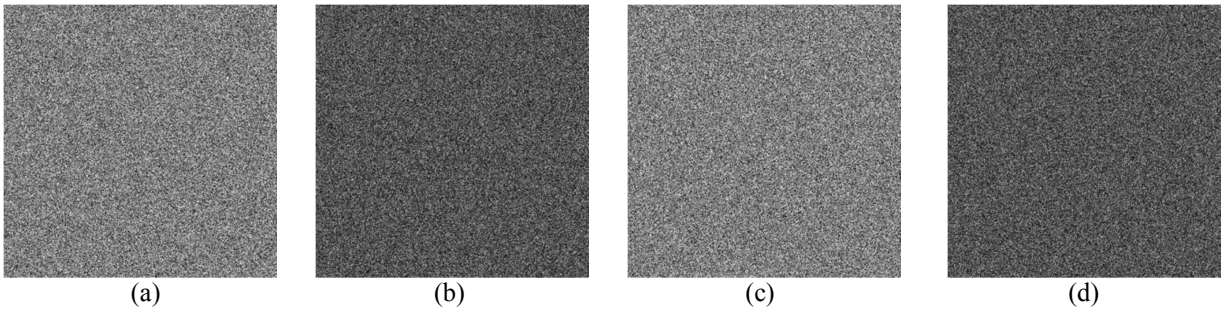
Fig. 2 The histogram distribution of plain image and cipher image

5.3 Sensitivity Analysis

Sensitivity includes encrypted key sensitivity and plain image sensitivity.

First, we encrypt the original Barbara with a slightly change encrypted key (changing $x_1(0)$ with a precision of 10^{-14} compared to the encrypted key used in Fig. 1(b)). Fig. 3(a) shows the encrypted image with the changed key. Fig. 3(b) shows the absolute differential image between Fig. 1(b) and Fig. 3(a). With a simple computation, the difference between Fig. 1(b) and Fig. 3(a) is 99.59%, which means the encryption process is quite sensitive to the encrypted key. Tests on other secret parameters have similar results, so they are omitted from illustration.

Second, we encrypt a modified Barbara with a slightly change pixel (changing the last bit of the first pixel) using the same key that used in Fig. 1(b). Fig. 3(c) shows the encrypted image. Fig. 3(d) shows the absolute differential image between Fig. 1(b) and Fig. 3(c). The difference between Fig. 1(b) and Fig. 3(c) is 99.65%, which means the encryption process is quite sensitive to the plain image too.



(a) (b) (c) (d)

Fig. 3 Sensitivity Analysis: (a) Encrypted image with only wrong initial value $x_1(0)$; (b) Differential image between Fig. 1(b) and Fig. 3(a); (c) Encrypted image with modified Barbara; (d) Differential image between Fig. 1(b) and Fig. 3(c)

On the other hand, two indicators, *NPCR* and *UACI*, are computed to measure the difference between the encrypted images when the respective original images have only one bit difference. *NPCR* indicates the number of pixels change rate between two encrypted images, $E(m,n)$ and $E'(m,n)$, while only one pixel of the plain image changed. *UACI* shows the average intensity of differences between two encrypted images. They are calculated by:

$$UACI = \frac{1}{M \times N} \sum_{m,n} \frac{|E(m,n) - E'(m,n)|}{255} \times 100\%, \qquad NPCR = \frac{\sum_{m,n} D(m,n)}{M \times N} \times 100\% \tag{10}$$

where $$D(m,n) = \begin{cases} 1 & if \quad E(m,n) \neq E'(m,n) \\ 0 & if \quad E(m,n) = E'(m,n) \end{cases} \tag{11}$$

Generally, an encryption scheme is robust against differential attack when the NPCR value is over 99.6% and the UACI value is over 33.3%. The result of the proposed algorithm is showed in Tab. 1.

Tab. 1 The *NPCR* and *UACI* performance

Encrypted image	NPCR	UACI
Barbara	99.6317	33.4387
Peppers	99.6195	33.3815

Tab. 2 Coefficients of the original image and the encrypted image

Correlations	Original image	Encrypted image
Horizontal	0.9814	0.0156
Vertical	0.9632	0.0108
Diagonal	0.9127	0.0113

5.4 Correlation Analysis

Commonly plain image has strong correlations among adjacent pixels which makes statistical attack possible. To investigate the correlations of adjacent pixels of the proposed algorithm, 1000 pairs of two adjacent pixels (in horizontal, vertical, and diagonal direction) are randomly selected from the plain Barbara and the respective encrypted image, and the correlation coefficient is calculated by the following formula:

$$r_{xy} = \frac{E(x - E(x)E(y - E(y))}{\sqrt{D(x)D(y)}} \tag{12}$$

where $E(x)$ and $D(x)$ are the expectation and variance of variable x, respectively. The average results are given in Tab. 2. It is clearly that all kinds of the correlation coefficients are extremely near zero which denotes low correlations.

5.5 Information Entropy Analysis

Information entropy is an important indicator of randomness in information theory. The information entropy is calculated by:

$$H(m) = \sum_{i=0}^{2^N - 1} p(m_i) \log_2 \frac{1}{p(m_i)} \tag{13}$$

where $p(m_i)$ represents the probability of symbol m. In the gray scale image processing case, there are totally 256 possible outcomes of the signal with equal probability. Thus, the information entropy should ideally be $H(m) = 8$ for an encrypted image. The test results of information entropy for encrypted image are listed in Tab. 3.

Tab. 3 The information entropy performance

Encrypted image	Information entropy
Barbara	7.9981
Peppers	7.9963

Tab. 4 Comparison of speed performance

Image size	Encryption speed of proposed algorithm(ms)	Encryption speed of DES(ms)
256*256	15	46
512*512	48	181
1024*1024	190	683

5.6 Speed Analysis

In practical image transmission, expecially in real-time internet applications, the encryption time must also be considered. Measurements of encryption speed of images with various sizes by using the

proposed algorithm and the well-known DES algorithm are listed in Tab. 4. The runing envirenment in the test is: Windows 7, Matlab 7.8, 2.6 GHz Intel Core2 Duo with 4GB memory. From Tab. 4 we can see the proposed algorithm is advantaged and it is fast enough for practical applications.

Conclusions

This paper proposes an image encryption algorithm with a dynamical feedback operation based on sensitive chaotic maps. The proposed algorithm has a simple structure that combines two primitive procedures: permutation and substitution. Each encrypted pixel is dynamically confused by its two respective previous adjacent encrypted pixels which greatly enhances the complexity and security of the algorithm. Several security and performance analysis are carried out to illustrate that the proposed algorithm has good encryption performance.

The Application of the Movement Video Analysis Technology in the Sports Area

Xiao Xiao

Physical Education Department of Nanyang Institute of Technology Nanyang 473000

Keywords: Movement Video; Analysis Software; Network Technology; Multi-Media Technology

Abstract. In this paper, the author starts from the literature reviews and the development and application of the video analysis technology software in the sports area, discussing the movement video collection, the processed and transformed digits from the computer software. Through the application of the first-line coaches and teachers in the sports teaching course, the athletes or students can see the technical action and tactical implementation effects, get the timely and accurate analysis information of which it will be beneficial to put the language style into the intuitive image, make the exchange for the coach or the students at the spot. In this way, the sports training and the teaching results will be greatly improved.

At present, the visualization technology of the multi-media computers and the Internet in the motion analysis is setting off a revolution in the action skill improvement. It is long-standing to guide the athlete with the motion video analysis techniques. in the 1980s, the sports video analysis technology is widely used to the sports programs in the European countries. In the sports teaching process, students are able to see their technical movements and immediate tactical effects after the training, and get the quick and accurate analysis, change the language style into the visual images, make the live exchange for the teachers and students. In this way, the technology will be greatly applied to the increasing effectiveness of the sports teaching and training levels.

The Application of Video Analysis Technology in Physical Education Teaching

1.1 The Collection and Organization of Video Analysis Materials

Firstly, it is necessary to confirm the technical analysis action requirements in a project. you can download the information via the Internet or make a record by yourself. Generally, you can use an ordinary video equipment or a high-speed video equipment to record the video. according to the characteristics of each project, it needs to install a video capture device of which the capturing steps are divided into the following steps:

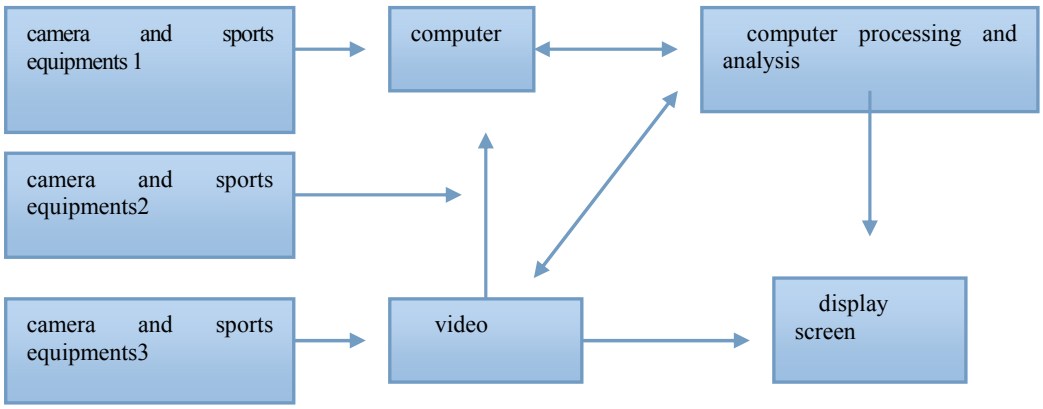

Figure 1 The major steps of video captures

Then entire collection equipments consist of two parts: one part is to complete the shooting, storage, and playback, delay and other requirements in terms of motion video; another part is the processing and analysis works in sending the commands to the computer, collecting the interesting

action video for the teacher or student. The images and related data processing results can be displayed in the big screen TVs and the computer display. In the computer, it is able to enter and store the collected video materials from the IEEE -1394 high-speed input interface or the video capture card.

Currently, the major domestic and international analysis system software are three-dimensional analysis software like dart-fish4.09 (Germany), sinimotion 3D7.2 (Switzerland), USA Ari-el, the gold medal coach DVCoach system. In the computer, the shooting films or images will be stored. The above mentioned software is used to organize and classify the interesting action videos for the teachers or the students.

1.2 Video Analysis

Through the collected digital video or the comparison methods, The main function of the sports video analysis technology is to improve the teachers' teaching level and the sports training level so that there is a higher level for the school sports training, competition and sports teaching process. For example: the sports video analysis software can offer the visual feedback in a direct, convenient and fast way of which the effective platform allows the students and teachers to make the technical communication and exchange; After the training, the sports video analysis software can also provide the in-depth analysis in comparing the completion situation of the technical action. The existing video analysis software has the following functions: video broadcast, manual drawing of video analysis, action video panorama synthesis, action video superposition contrast, the parameter acquisition of the human body motion , motion curve display and analysis. In sports training field, the quick feedback functions of the technical movement image is accessible to repeatedly play the students' immediate technical training. At the same time, it is able to take the technical video about the excellent students in the hard disk so as to make a comparison and analysis. As well, the freezing effects of the action video panorama is used to analyze the changing process and trajectory in a statical way so as to make an analysis about the understanding and completion of the action. It is able to overlay and compare the students' action with the video of the excellent athletes' action in the analysis software of which a seamless video is produced. In this way, the difference of the two actions can be clearly discovered for the athletes to master the essentials and improve the physical training performance in a faster way. With the powerful analysis and drawing tool (Figure 2) , it is able to calculate its speed, angle, height and length. The data table will be automatically generated so as to automatically track and calculate the changing data size, and then display and output the data in a generic data sheet. The teachers' training and scientific researches will be greatly improved.

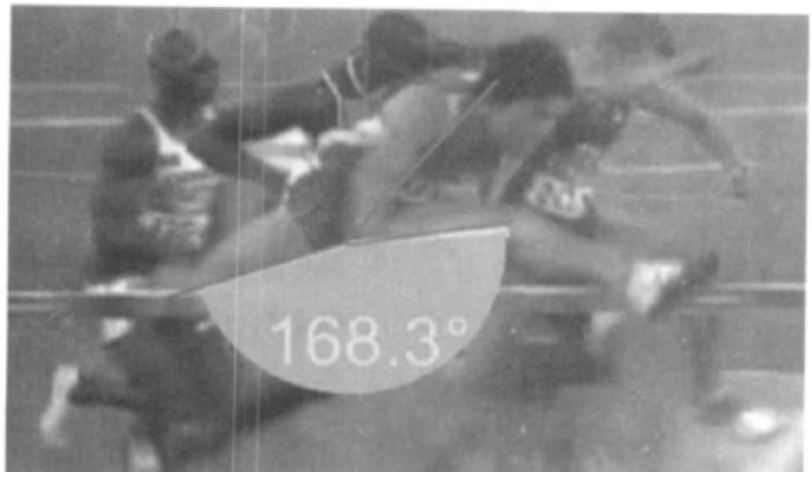

Figure 2

In the whole process, the teachers can extract all the technical parameters of the students (such as joint position, angle and angular velocity, etc) through the analysis software. with these analysis information, the teachers can provide the guidance and advices for the students in the training of which it is conducive for the improvement of the students' training level. These data are compiled

into a database so as to simulate the action. In the analysis software, it needs to enter the three-dimensional structure of the athletes. After that, the action will be converted into a standard level. In the process of training and teaching, the contrasting results will be sent to the students through the big screen or other media. For example, the human body motion parameters in the gold coach DVCoach system is based on the tracking technology of the human body movements in the video, acquiring the movement trajectory of the major human body parts and the joint angle. In figure 3 and figure 4, it shows the athlete's chest motion curve in a springboard game.

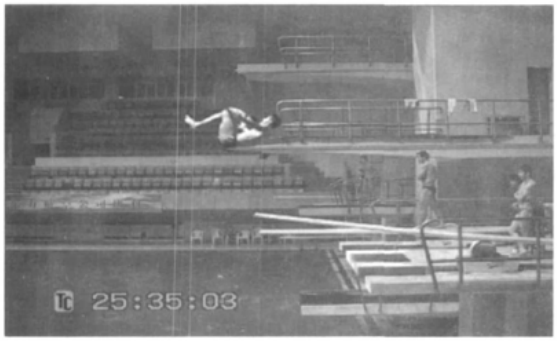

Figure 3

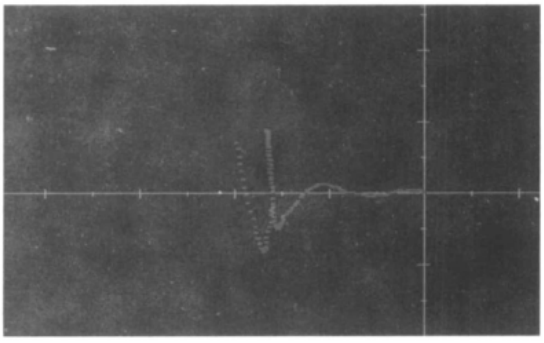

Figure 4

In the SimiMotion system, the technology parameters is used to construct the three-dimensional simulation model of the human body as well as the virtual movements under the background as stated in Figure 5 and Figure 6.

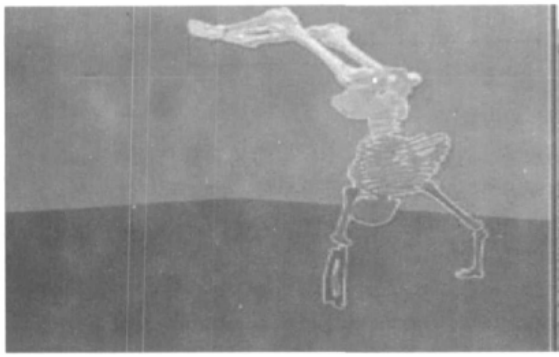

Figure 5

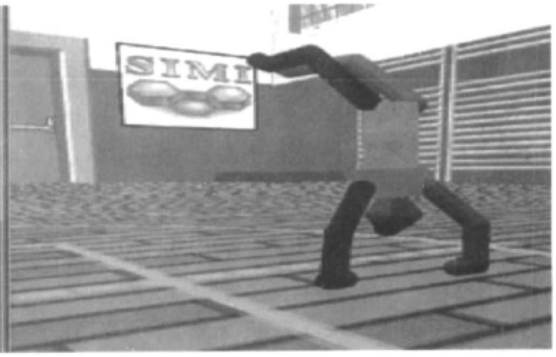

Figure 6

2 The unsolved issue of the sports video analysis technology in the sports teaching and training

With the rapid development of the computer and network technology, the training place or school takes form of the single unit. It is short of the connection for the multiple units. Without a network and data system, it will seriously affect the efficiency and sharing of the video analysis results. In this condition, it needs to firstly establish a huge sports video analysis database with the WEB2.0 technology (including blogs, RSS, peer-to-peer, instant messaging TM). In this way, the scattered units will be quickly assembled into a huge database while the it is able to make the exchange and information sharing in the network platform.

As a new technology, the sports video analysis has been widely used in the sports circles. Due to the equipments and the high cost to use, the rich data content has limited the development of the technology. According to the current situation in the domestic, the national team and a few of the provincial team is equipped with this device. There are less than 15 devices in the sports colleges in all. The high cost and the technology of the self-developed software is also undesirable. The professional video processing software (e.g., corel video studio pro multilingual10.0, Flash) is not professional while the obtained data is not quite accurate so that the data is difficult to be applied in the actual situation. In addition, the computer training for the physical education teachers is relatively lagging of which it has limited the use of the software. The computer level for most of the sports teachers shall be improved.

In the current sports circles, the application of the sports video analysis in the sports teaching and training is still relying on the teachers' naked eye observation, and undertake the action correction for the student in oral language. The students are difficult to form a definite concept of image in terms of their actions of which it will affect the correction of the action. Due to many technical actions are completed in an instant moment in the teaching, the fine point is difficult to be distinguished with the naked eye. Since the sports video analysis technology is applied in the communication of the teachers and students, the action analysis will be helpful for the students to speed up the comprehension of the action requirements and quickly improve the understanding of the correct action. With an intuitive understanding of their actions, they can quickly correct their wrong actions of which it accelerates the physical training courses study and physical exercise performance. For the students, the training can change, consolidate and improve the students' competitive ability of students in getting the good grades in the game. The competitive sports will go after the faster, higher, and stronger development. In a strict sense, the training process is to constantly find and solve the problems. Sports video analysis technology is not only applied in the communication of the teachers and students, not only becomes the platform for the Chinese and foreign teachers. The contrastive video analysis in the training and actual combating process help the students to better understand the teachers' demand on the actions and rapidly improve the performance. Through the contrastive action video analysis of the outstanding students, the advanced technology are understood in the world for the students's simulation and learning. Through the contrastive action analysis of the training and the match, the students' practical ability is strengthened. In particular, the action deformation and others are perceived with the changes of the psychology and endurance. With the help of the Dartfish software, the researchers of Beijing Institute Of Sports Science make our hockey ball defender Ma Yibo become one of the athletes who can master the skill action in the world.

The emergence of the sports video analysis software has greatly raised the level of sports training. In the future, the training process will certainly combine with the coaches, students, sports video analysis system software and network. The establishment of the sports video database will promote the development of the physical education teaching for the development of the national fitness campaigns. The traditional training pattern will disappear instead the training and teaching mode will be covered with the advanced technology and science and the reasonable training and teaching.

Keywords: Anti-counterfeiting technology, Information encryption, Halftone screening technology, Moire effect

Abstract. Moire effect is a special optical phenomenon caused by the interference of light. In the printing industry, it is also called Moire phenomenon which is caused by superposition of the multicolor printing dots for halftone images. Now it is widely used in the anti-counterfeiting areas. In this paper, we firstly introduce the basic principle of Moire effect. Then we describe several main applications of the Moire effect in the field of halftone image security. We review the main types of Moire-based anti-counterfeiting methods, compare them, and explain how they can be used for such security applications. It will provide the necessary technical information for the persons that in anti-counterfeiting area.

Introduction

Moire effect is a visual perception that occurs when viewing a set of lines or dots that is superimposed on another set of lines or dots, where the sets differ in relative size, angle, or spacing. In the printing industry, the Moire pattern is an artifact that occurs in the print reproduction process when any two, or more, repeating patterns overlap each other. Usually it is a harmful optical phenomenon when we print the multicolor halftone images. Many technicians are trying to find the method to avoid this problem in order to achieve better printing quality. However, it was found that the Moire patterns in the halftone images can be used in the anti-counterfeiting areas through special design or screening methods. To be specific, the Moire patterns are embedded in the halftone image by the peculiar screening technology invisibly. If the image is reproduced by scanning or photocopying simply, the latent image will be appeared. So the halftone prints with the anti-counterfeiting technology are difficult to copy. Moreover, the greatest advantage of this technology is that the security cost is low. In order to acquire good security effect, the designers can screen the image by the specific software when they make the printing plate. There is no other material cost during this simple process[1]. Therefore, it is an important anti-counterfeiting technology which is increasingly accepted by the printing industry.

The Principle of the Anti-counterfeiting Technologies

Normally, the Moire patterns can be avoided in this new technology, and we can only find them with special tools. Firstly, the image should be divided into two parts, the hidden figure area and graphic display area. Then these two parts are screened with different screen angles. If we print this image, you cannot find the hidden information. However, if someone should see the embedded information, he must use a decoding tool.

The specific process is as follows. The original image and the embedded information (image or characters) are inputted into the computer respectively. Then the encrypted methods which are also known as special screening technologies are used to obtain a new halftone image. Meanwhile, a decoding image showed with specific screened dots is generated by the corresponding algorithm, and we can output it onto a transparent film. If we put this film onto the printed image in the right place, the hidden information can be seen clearly. The screening algorithm for decoding information into the image is unique, and the counterfeiters are difficult to crack it. Also, we do not need any other materials in the whole process, so it is a cost-effective anti-counterfeiting technology[2].

The Main Methods for Anti-counterfeiting Technologies based on Moire effect

Phase Modulation Methods. This is a very simple method for hiding and extracting latent image. This method is based on the physical presence on the document of a latent image, which is generated using a technique known as "phase modulation". In this technology, we firstly print a fine, uniform line grating or screen of dots on the substrate, but the same line grating or dot screen is printed in a different phase within the predefined borders of the latent image. Because of the high frequency of the lines or dots, the latent image which printed on the substrate is hard to distinguish from its background. But when a reference transparency comprising an identical but unmodulated line grating or dot screen is superposed on the substrate, thereby generating a Moire effect, the latent image predesigned on the substrate becomes clearly visible[3].

As shown in Figure 1, let A and B be two identical line gratings with a small period. Assume that within the borders of a given shape, the parallel lines of grating A are shifted by half a period (see Figure 1(a)). Because the period is too small, the whole image seems uniform, and the latent image cannot be seen. If we print the line grating B on a transparent film by the same period with no latent images (see Figure 1(b)), and then superposed it on top of grating A at the same angle, there will be two results. It is showed in Figure 1(c) that the two gratings are superposed in-phase, and Figure 1(d) shows the superposition when grating B is shifted by half a period. Therefore, grating B can be seen as a decoding tool which can find the latent image hidden in grating A. The normal reproducing equipment cannot copy the gratings totally because of the high frequency, and we can obtain a uniform gray-level image after reproducing. If you put the decoding latent image on the same area, the original latent image is invisible.

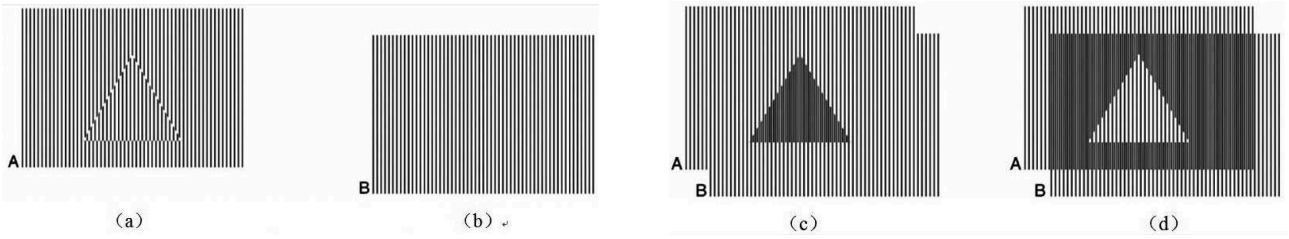

Fig.1 The basic principle of phase modulation methods

Grating Extract Methods. This is a way combined with the halftone image screening technology and optical reflection characteristics of the grating materials. When the grating sheet superposed on the prints, lenticular grating lines are interference with the printed dots based on Moire effect. It is occurred only in the situation that the lenticular grating lines and the dot lines are in the same direction. Then the embedded dots will be displayed. Therefore, we embed the information by processing the screened dots, and then detect it with the lenticular gratings. It is called as the grating extract method for anti-counterfeiting[4].

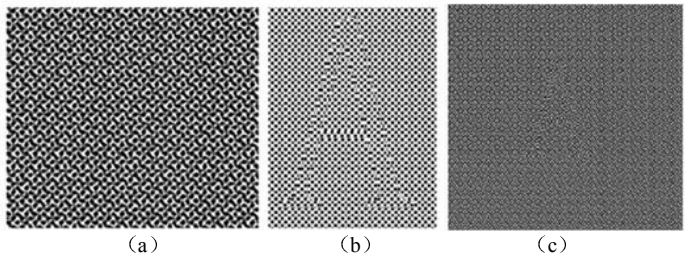

Fig. 2 （a）Original halftone image
（b）The channel of hidden information
（c）Overlaid halftone image

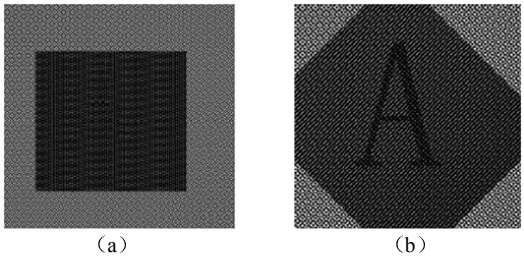

Fig. 3 （a）View in angle 0°
（b）View in angle 45°

During the process of this method, we firstly superimpose the four channels of the primary color; the result is showed in Fig 2 (a). Secondly, choosing a channel for hiding the special information, usually, we make use of the black channel. There is an A shaped area which is selected as the hidden area showed in Fig 2 (b). Then we move the dots in the specific area and hide the information in the

black channel. After that, the processed channel can be combined with the other three halftone channels. And the overlaid halftone image is obtained which is showed in Fig 2(c). If you want to detect the hidden information, a special lenticular grating should be put on overlaid halftone image. We can observe the different effects by changing the angle of the grating changes. Fig 3(a) shows the result of the image with an angle of 0 degrees of the grating, and Fig 3(b) shows the result of the image with an angle of 45 degrees of the grating. Because the screening angle of the black channel is 45 degrees, so we can see the hidden letters with this angle.

The 2D Moire Methods Based on the Microstructure Screening Technologies. Both two methods mentioned before are relatively simple, they are widely used in the printing industry. With the development of high-precision scanning technologies, the reproducibility of them is a problem recently. The 2D Moire methods based on the microstructure screening technology is put forwarded by Amidror from EPFL, Switzerland. The image must be microstructure screened firstly, and then choose decoding tools. There are two different points between the new method and the phase modulation methods. One is a way that we embed the hidden information with the microstructure dots in the screening process instead of the method of phase shift for inputting the latent image, and in the screening process using different shaped microstructures directly outlets directly into the implicit information; the other one is that the hidden information is decoded with a 2-fold periodic pinhole array rather than a 1-fold periodic grating made of linear slits. Three parameters in the new method must be strictly controlled, namely, the line screen, screen angle and dot shape. The theoretical basis is more complex, detailed explanation can be found in the reference[5].

Although the technical principle is slightly different from the other methods, the process is similar. We firstly screening images with the microstructure dots with the art "D" shape showed in Figure 4.

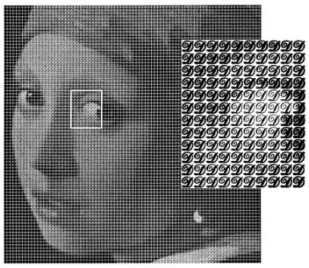

Fig. 4 The image screened by microstructure with local amplifier

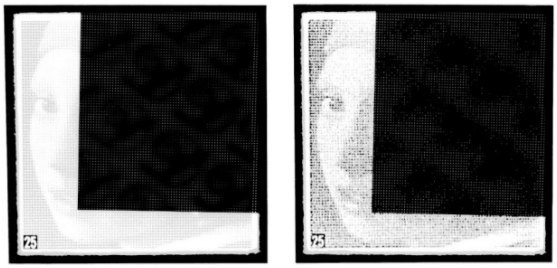
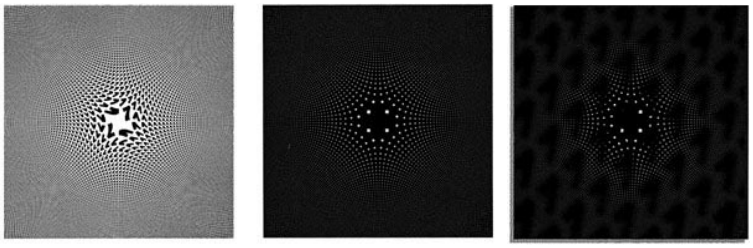


(a) (b)

Fig. 5 The diagram for the decoding image superposed on the origin and the copy

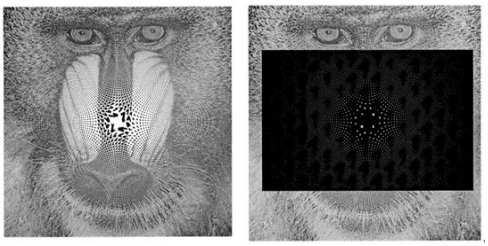
Due to the higher screening rulings, we cannot find any difference between the obtained halftone and the image screened by the traditional technology. But the hidden information is embedded into specific contour of the dots. The role of decoding tool is that it can amplify the tiny dot contour information in order to obtain the hidden information directly through the naked eye. The decoding tool is a 2-fold periodic pinhole array in the black background. We should superpose the decoding tool on the prints in the right position. If the hidden information can be seen just like the image showed in Fig 5(a), we can decide the authentication of the image. Otherwise, the destroyed image can be seen as it shows in Fig 5(b) which may be copied by duplication.

A specific function can be used for distortion of the microstructure screened image in order to increase the strength of security, and the distorted image is showed in Fig 6(a). The corresponding pinhole array in the decoding film should be distorted (Fig 6(b)). Then, the original contour information can be restored by the two images superimposed together (Fig 6(c)). It is difficult for counterfeiters to obtain the information directly from the image because of the uniqueness of the deformation function. Figure 7 is obtained with this method, and it can achieve better anti-counterfeit effect[6].



（a） （b） （c）

Fig. 6 （a）Image transformed with the specific function （b）The same transform with the decoding image （c）Decoding result



（a） （b）

Fig. 7 The diagram for the anti-co counterfeit effect by the method of Fig 7

In addition, the pseudo-random screening algorithms can be used in this method. In these variants, pseudo-random dot screens are used rather than periodic ones, and as a result the Moire effect which is obtained in the superposition is no longer periodic. It further improves the difficulty of counterfeiting[7].

Conclusions

The above studies proved that the anti-counterfeiting technology for halftone image based on Moire effect can achieve better security effect. We can widely use this method in document protection because there is no other material cost during the whole process. Also, with the rapid development of technology, a single security technology cannot meet the growing demand for anti-counterfeiting marketing. Further research will be focused on the combination of multiple anti-counterfeit techniques which is the trend of security domain.

Keywords: Motion Image Retrieval;Based-Static Image Retrieval;object segmentation;image index

Abstract. In the face of mass movement of image data storage management and retrieval applications, traditional search techniques and methods have been completely incompetent. The emergence of the technology on Based-Static Motion Image Retrieval, points out a specific direction for the development of the field of information retrieval. First of all, the thesis analyze the basic principles of the Based-Static Image Retrieval technology and Based-Static Motion Image Retrieval technology. And the thesis discuss mainly the relevant key technologies and development situations whose based on the static motion image retrieval technology. Secondly, the thesis Introduce and analyze, briefly, the characteristics and application background of several motion image retrieval prototype system, which developed by the domestic and foreign research institutes.

Introduction

With the rapid development of electronic information technology and the progress of motion image acquisition equipment and the means of acquisition, the digital motion images have a very wide range of applications in the field of industrial, commercial, transportation management, military, etc. With the development and progress of the image analysis and motion image processing technology, the application of digital motion images, from the original motion image recording and motion image monitoring, is developing to the application of the Intellectualization motion image.

Facing the storage management of massive motion image data and retrieval applications, especially in the static-based analysis and retrieval application requirement, the Based-Static Motion Image Retrieval (BSMIR) emerge as the times require. Static-based image retrieval technology , a kind of fuzzy query technology , find out the closest image [1] to the query requirements in the feature space, through extracting the visual features of the image (color, texture, shape, spatial relationships, etc.) and semantic features (feature semantics, object semantics and abstract semantics) .

It based on the static of the motion image and context, extracts and descripts the feature and the static of the motion image automatically, in the case of no human involvement, so as to realize the technology and method of motion image data retrieval from the large-scale motion image database. Organization of the Text.

The feature of BSMIR

BSMIR is different from the traditional keyword-based retrieval and its main features embodies in [1]: it is based on the knowledge as image processing, pattern recognition, computer vision and image understanding.

It can, drawing on the knowledge and the data presentation as cognitive science, artificial intelligence, database management and human-computer interaction and information retrieval, Achieve Based-Static Motion Image Retrieval function by introducing a new media data, data mode, as well as effective retrieval algorithm and friendly man-machine interface. BSMIR which is relative to the method of the traditional text-based retrieval has two prominent characteristics: It breaks through the limitations of traditional retrieved based on the expression, And Analyzes Directly on the static of motion image. The process that the computer extract features and semantic automatically Avoids the subjectivity of artificial described.

It achieves Based-Static Retrieval by making use of these static to build aspect indexing and adopts the method of similarity matching to Query.

BSR technology and its Research status

Since the existence of the inevitable contact between the motion image and the image— The motion image is a sequence of the moving image.

The image is a frame of still motion image. In the research of Based-Static Image Retrieval, there are many technical issues of common concern in the BSMIR. Therefore, below is a brief introduction about Based-Static Image Retrieval techniques.

2.1 BSIR technology and its development situations

It is a hot topic in the image database study that BSIR technology, which starts with characteristic analysis and comprehension of the image mainly, take the advantage of vision features (color, texture, shape, spatial relationship, etc.) and semantic features (semantic characteristics, object semantics and abstract semantics) of the image to Retrieval In recent years.

Color is an important visual information. It has the features such as simple computation and stability, and has a strong robustness to rotation, translation transformation and the various deformation. It has become one of the characteristics of the most widely used in the existing retrieval system [1].

The common methods of color features include: histogram method, the cumulative histogram method, Color histogram method, color layout method, central moment method, etc. and the histogram method is one of the most commonly used method.

There is no formal definition for texture currently. it Is generally believed that the texture is the regular permutation and combination of the texture elements .but people regard the regional of Repetitive, simple shape and consistent strength as the texture elements. According to the psychology study of human towards the visual perception of texture, Tamura [1] put forward the expression of texture features, mainly including Roughness, directional Directionality, Contrast, Line-Likeness Regularity and Coarseness. After decades of research, the texture feature extraction methods have been proposed many methods [2], for example:Gray Level Difference Statistics method, Gray Run Length method, Spatial Domain Energy method, Regional Texture Primitive Parameter method, Co-occurrence Matrix method, the features extraction based on the texture spectrum , the texture features extraction based on mathematical morphology ,etc.

2.2 BSMIR technology and its development situations

(1) The motion image feature extraction

The motion image features including the underlying visual features and high-level semantic features. The extraction of the underlying visual features such as color, texture, shape, spatial relationship are basically the same as the method of the image feature extraction .The following main about motion feature of motion image is discussed. The motion is a unique feature of the motion image data, it shows that the development and changes of the motion image static in the timeline, and has a very important role for the description and understanding of motion image static [1].

Motion in the motion image is mainly divided into two types: motion of background and foreground. Background Motion is the overall movement of all pixels within the lens caused by the movement of the camera, also known as Global Motion or Camera Motion; But the Foreground Motion refers to the motion that the object being photographed in the scene, also known as Local Motion.

The methods that express and descript the motion information of the motion image mainly include: using the parametric motion model to describe the global motion , describing the local motion ,with the help of image segmentation and target tracking, describing The motion activity attribute of the motion image' static activity intensity level.

From the above three description methods, MPEG-7 recommended a descriptor respectively. There are two main kinds of methods for motion feature extraction and calculated / estimated: One is based on gray element time changes, thereby calculating a dense optical flow of the respective pixels. Under reasonable limitative conditions, two unknown components of the optical flow field can be obtained by solving a set of nonlinear equations.

The other is a group sparse features based on the first extracting the target, and track them in subsequent frames. Once the corresponding relationship is established among frames, and certain restriction is established according to the feature of target, motion component also can be obtained by solving a set of nonlinear equations.

The parameters of global motion estimation methods mainly include [3]: improved hybrid least squares estimation method, least square estimation method, iterative least squares estimation method, etc. Two main kinds of study on the feature extraction of the local motion in the motion image [4]:

Local motion vector field and motion image object motion trajectory.

Trajectory describes the object of the motion image during the movement, and the motion image feature is extracted by extracting motion information and its trajectory from the motion image sequence.

The trajectory can be usually directly obtained by the MPEG compressed stream α channel.

However, the effect is usually not very ideal that relying solely on the motion information retrieves the motion image data. In most cases, it needs to combine with others visual information features in order to achieve a satisfactory retrieval result.

(2) Motion image object segmentation

MPEG-4 introduces the concept of a motion image object to support object-based functions. It allows users to apply and study the specific algorithms according to the concrete applications, rather than obtaining the concrete methods of the motion image object from the motion image sequence.

Many domestic and foreign scholars have proposed a variety of motion image object segmentation algorithms can be roughly divided into two categories: motion segmentation based on time-domain information and segmentation method combined with temporal spatial domain information.

The earliest object segmentation based on time-domain information method is segmentation method based on optical flow field.

Based-motion-similarity Time-space object segmentation algorithm, which based on region segmentation, calculates the features of region motion and combines with image regions to form the motion object segmentation, according to the similarity of the regional motion .It can also realize object segmentation by clustering algorithm Based on region segmentation. Bayesian space-time object segmentation algorithm implemented at the regional level is a kind of motion object segmentation technology. Because of the image area with color, texture, shape and other characteristics, and the region motion features calculated by estimating region motion, the space-time Bayesian object segmentation algorithm separates object integrating the features of image and motion. The region tracking provides consistency clues of region motion in the timeline, in a period of time. Through the analysis of the spatial relationships in the area, you can take advantage of the regional time consistency to separate the segmentation motion image object.

(3) Motion image indexing technology

For the motion image data, you can build two indexes; one is based on visual features that can be extracted from the key frames; the other is the semantic primitive index based on the target or motion, which is usually more complex and needs further comment after the extraction.

The index based on visual features is to index the meaning that the visual primitives carry [3].According to Symbol linguistic analysis here, the meaning that visual primitives carry can be regarded as the meaning that symbols combination transmit, so it can be automatically extracted by checking the low-level visual features and combinations.

The visual nature can be modeled as a multi-dimensional feature points, such as color, texture and shape, so the index structure can use point access method. The performance of point access method depends on the number and the distance metric used by expression of the nature in the actual. For most point access method, its performance will decline in the number of features over 10 [1].Therefore, the high-dimensional data is often mapped to low-dimensional space before the index. Because the characteristics of visual features and field have a minor relevancy, the index based on visual features is more applicable to a variety of different motion images, and visual features automatically extracted from the motion image using image processing and analysis technology. The index based on semantic features is to index some semantic primitives around the target or visual elements which carry the meanings.

Some of the target elements can be extracted from the key frames, and compared with that from the query graph.

The motion image static is very complex, covering a broad field, so the motion index extraction is quite complex.

The motion image retrieval system technology and Its Research situation at home and abroad

At present, domestic and foreign have developed a number of the prototype system Based-Static Motion Image Retrieval [3], among them, the more famous are IBM's QBIC system, VisualSeek system that the joint research of the Columbia University, Department of Electronic Engineering and Telecommunications Research Center Image and Advanced Television Laboratory,

IDVL researched by Carnegie Mellon University, VideoQ system developed by Columbia University, TV-FI (Tsinghua Video Find It) motion image program management system developed by Tsinghua University, Webscope-BSMIR developed by Zhejiang University, etc. Although they, in terms of performance, cannot fully meet the needs of the business, but still has a higher theoretical reference value. QBIC system allows to use the example images, user-constructed sketches and drawings with their chosen color , texture patterns, and the lens and target motion graphics information, to query the large image and moving image database. VisualSeek is a based-static retrieval system on the Internet, collecting images and motion images through a automatic network engine in the network. it can automatically analyze and build indexes with images and motion images, which can be placed in a certain topic categories. IDVL developed by the Carnegie Mellon University specifically includes: the motion image segmentation, the motion image character recognition, the pronunciation analysis and recognition, the natural language processing, the face detection and so on, to retrieve and summarize the motion image data. VideoQ extends the traditional query method based on keywords and themes, allowing the users to retrieve image motion with the visual features and temporal and spatial relationship.

Concluding Remark

The motion image retrieval is no only one of the important research topics in the field of multimedia, but also the most extensive and difficult topics involving the subjects, which has made some achievements after years of research.

But there are still many technical issues to be further in-depth study and exploration for motion image retrieval.

For example, how to combine motion image low-level features with high-level semantics organically, how to design effective motion image similarity measures for multiple types of features, how to meet the comprehension of motion image similarity foe human .

Keywords: Image Retrieval; Weight-Vector; Particle Swarm Optimization; Relevance Feedback

Abstract. As the physical meaning of components are different in feature vector, this paper presents a weight query vector based on QPM to represent the user's true intention more properly, and then proposes two RF frameworks to learn the weights for positives and negatives in the feedback process of CBIR by PSO. Experiments were conducted to validate the proposed frameworks based on color histogram weight-vector. The proposed frameworks were compared and outperformed four other relevance feedback methods regarding their efficiency and effectiveness, thanks to the fact that they can make full use of the features' different importance.

Introduction

Relevance feedback (RF) technology has been shown to provide significant performance for reduce the semantic gaps in CBIR [1] [2]. QPM is an RF method used in CBIR, however there are three parameters need to be fixed. What's more, it does not consider the different importance of feedback images [3]. Therefore, improving the query vector may express the user's real query intentions better and raise the accuracy of retrieval. Image retrieval problems can be seen as a problem of optimizing query vector. Nowadays, many studies about image retrieval have done with particle swarm optimization (PSO) algorithm [3] [5] [7] [8]. Optimize query vector by PSO is to weight distribution of features through learning users' intention and adjust the weights dynamically and find the optimal solution by iteration.

On the basis of Rocchio formula, Jing proposed the weight QPM algorithm [5]. However it does not take the query vector obtained previously into the feedback iterative process, which can make the query information loss. PSO-CBIR [6] is a preliminary version first introduced through its effective space exploration mechanism to find the most similar images by iterative between particles. Evolutionary PSO-RF [7] redistributes the weight of feature vector dynamically. However, it has not consider the effect of former retrieval results directly, then a PSO-based interactive image retrieval [4] is proposed, it use particles' movement to adjust the weights of positive and negative cases in relevance feedback dynamically, finally optimize the query vector.

For the methods mentioned above all put forward based on the query vector, PSO is useful in learning the weights of positive images and negatives while weight-QPM is also meaningful. As we know the physical meaning of the various components' in feature vector may be different, we propose a weight query vector by improving the Rocchio equation with weight-vector. And then we put forward a PSO-based weight-vector techniques to optimize the query vector by PSO.

PSO-based weight-vector RF algorithm

As an index of visual features, we change it into weight-feature first, and then determine the initial weight query vector by QPM function, if the user is not satisfied with the initial result, adjust the weight query vector according to users' feedback information to let it closer to the positives, far from the negatives. On this basis, we use PSO for optimization, propose a PSO-based weight-vector framework,.

PSO-based weight-vector algorithm constructs weight query vector by taking use of $TF \times IDF$ model [7] to calculate weight-vectors and reconstructs it by PSO, finally outputs results by similarity matching.

2.1 Weight-Vector

In this paper, the composition of weight-vector is based on $ci \times ici$ technique [8]. The component importance (ci) is reflecting the relative importance of a feature component in feature internal, and the inverse collection importance (ici) is reflecting the difference of this feature component with component of other images.

Assume the feature vector of $i\text{-}th$ image is $F_i = [f_{i1}, \ldots, f_{ik} \ldots, f_{im}]$, we define,

$$ci_i = [\frac{f_{i1}}{mean_1}, \ldots, \frac{f_{ik}}{mean_k}, \ldots, \frac{f_{im}}{mean_m}], \quad (1)$$

$$ici_i = [\log_2(\sigma_1 + 2), \ldots, \log_2(\sigma_k + 2), \ldots, \log_2(\sigma_m + 2)], \quad (2)$$

where $mean_k$ is the mean value of component feature f_{ik} in all the features, σ_k is the standard deviation of the $k\text{-}th$ component of ci in all the features. Then the weight-vector is $w_i = ci_i \times ici_i$. While ci is a normalized representation for every component of feature that can reduce the different range of values, ici_i can use standard variance to weaken the effect of non-relevant component in features.

2.2 Weight Query Vector

In general, different descriptors are combined statically in retrieval process [8], if they can be combined more complex, users' visual perceptions can be characterized better. Allocating same weights to positive images in QPM, the distinctive importance of feedback images does not take into account, neither of the negative ones, that is, the query vector is not the optimum, it need to be improved. We changed it as,

$$Q_{i+1} = \alpha Q_i + \frac{1}{rel} \sum_{I \in REL} \beta_I w_I - \frac{1}{irr} \sum_{J \in IRR} \gamma_J w_J, \quad (3)$$

where Q_{h+1} is the updated retrieval vector while Q_h is the primary one. REL is a set of positive images indicated by user, and rel is the number of this set, similarly, IRR is a set of negative ones annotated and irr is its number. β_I, γ_J are different weights for different positive images and negative ones correspondingly that can be learned according to the feedback information.

PSO is starting with a group of initial solutions that randomly generated, and changing the velocity and location toward its pbest and gbest. We can get the optimal weight through learning the different importance of positives and negatives by PSO to construct the optimal weight query vector.

Experiment and Analysis

This paper conducted experiments based on color histogram and use Euclidean distance for similarity matching on Corel 1000 image database, an image library with 10 categories：Africa, Beaches, Monuments, Buses, Dinosaurs, Elephants, Flowers, Horses, Mountain, Food, each category of 100 images. Experimentally, the population size is selected as 60, five times of iterations, and the training set is 35, 0.95 for the inertia factor w, two acceleration factors set as $c_1 = 2, c_2 = 2$. N is assigned as 20.

First we give an effective instruction for the 10 categories. (1) For the categories have single background and outstanding theme, such as Dinosaurs, Flowers, only using 3 times positive feedback or even just 1 time positive and negative feedback can we get a relatively satisfaction results, which basically show our method is more efficient to this kind of image retrieval. (2) For the categories have simple outline and outstanding theme, such as Buildings, Buses, good results can we get after 3 times feedback. Less time is taken as the users are more willing to accept. (3) Then for the categories have complex structure or confused semantic those are difficult to retrieval, such as Elephants, Beaches, Food, 5 times of feedback can be taken to ensure a satisfying results from the perspective of user, for which time is relatively acceptable.

Second, we compare with other intelligence methods on the condition that top N similar images are retrieved, such as PSO-based algorithm, Evolutionary PSO-RF and QPM algorithm. $AP(20)$ is (a) and MAP is (b) in Figure 1. Then we compared the Recall and Precision of retrieval, as (c) in Figure 1. As $P \times R$ curve shows, the algorithm achieved higher precision when recall is fixed in most cases. Also the algorithm achieved better recall when precision is fixed. That means, the proposed algorithm detects more related images with better sorts. With the increase of feedback number, our algorithm may some extent lower than the previous algorithm, because of the image feature itself, based on this, a further study can be done by choosing fusion weight characteristics.

Fig. 2. Retrieval results for different interactive technology

Conclusions

Two effective content-based relevance feedback frameworks, PSO^{+} -based weight-vector algorithm and $PSO^{\pm}$ -based weight-vector algorithm, are proposed in this paper based on particle swarm optimization and weight-vector. They all strengthen positive images and weaken negative ones by learning weights in feedback loop, and proved to be efficiency and effectiveness thanks to the fact that they can make full use of the features' different importance. We believe the retrieval accuracy will be further improved by considering the fusion features.

Keywords: Multiplexing Technique, Bipolar, APDCDM

Abstract. This paper propose a new multiplexing technique which use the bipolar RZ signal to realize duty cycle division multiplexing(DCDM) ,we call it Absolute Polar Duty Cycle Division Multiplexing(APDCDM).Multiplexing and demultiplexing principle of APDCDM are analyzed. Here we have designed a optical fiber transmission system based on APDCDM of three users by Joint simulation with Optisystem and Matlab. Simulation result shows the feasibility of this system. By the analysis of signal energy, explain APDCDM can carry more users than DCDM.

Introduction

Multiplexing is a technique amis at solving the problem of how to use one channel transmit multiple signals simultaneously .The mature research currently are Time division multiplexing(TDM) , wavelength division multiplexing(WDM) and Code Division Multiplexing(CDM).

The main issue of TDM is clock recovery. In WDM system, a user can only transmit data on a single carrier. Duty Cycle Division Multiplexing(DCDM)[1] We proposed before solved these problems. However, with the number of users increasing, The multiplexed signal energy increasing rapidly. For MZ modulator, the nonlinear effects of lightwave output will be very obvious when the signal voltage is larger.. In order to solve this problem, we propose a new multiplexing technique which use the bipolar RZ signal to realize duty cycle division multiplexing(DCDM) named Absolute Polar Duty Cycle Division Multiplexing(APDCDM).This technique significantly reduce the energy of the multiplexed signal so that the system allows more users thus improve the bandwidth utilization.

Working Principle

APDCDM is the improvement of DCDM. A APDCDM system with three users below is used for an example to describe the principle of multiplexing and demultiplexing. Figure 1-(a),1-(b) and 1-(c) show the duty cycle distribution of three users system, where 0.25,0.5,0.75 duty cycle are used to represent user 1,user 2 and user 3 .Noting that user 2 has opposite polarity to user 1 and user 3 .Use the Periodic signal 10101010,11001100,00001111 represent these three users' signal respectively. Amplitude superimposed on the timeline when the three signals multiplexed. The multiplexed signal shows in figure 1-(d) and the absolute polar multiplexed signal shows in figure 1-(e).The system can be extended to n number of users, for the system of n users, each user is set to the duty cycle of 1 / (n +1), 2 / (n +1), 3 / (n +1) ..... n / (n +1),the odd user's polarity is positive and the even user's polarity is negative. Multiplexing the same principle.

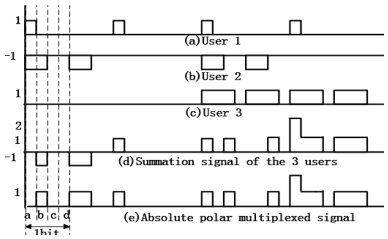

Fig.1 The multiplexing principle of APDCDM

Table1 The principle of demultiplexing

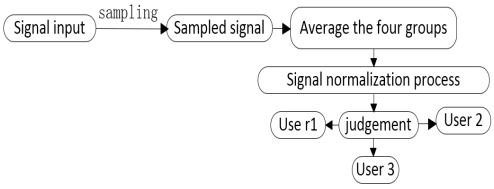
output1	output 2	output 3	a	b	c	d
0	0	0	0	0	0	0
0	0	1	1	1	1	0
0	1	0	1	1	0	0
0	1	1	0	0	1	0
1	0	0	1	0	0	0
1	0	1	2	1	1	0
1	1	0	0	1	0	0
1	1	1	1	0	1	0

In this paper, we designed a demultiplexer based on APDCDM with Matlab. The principle is shown below: divide every bit of the sampled signal on average into four segments as a, b, c, d. For three users, there are eight kinds of combinations, each case produces a unique waveform as shown in Table 1, we do demultiplexing just according to these 8 kinds of combinations. A de-multiplexing system of n users will be relatively complicated, the principle is similar to the former one. There are 2^n kinds of combinations and we do demultiplexing just according to them.

Simulation Experiment

a. The Design of Demultiplexer

In this paper, A demultiplexer based on APDCDM is designed by matlab, The design process diagram shows in Figure 2.



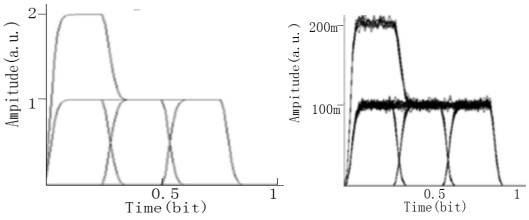


Fig.2. The design process diagram Fig.3- (a) Eye diagram of signal input Fig.3-(b)Eye diagram of the signal after transformed by optical fiber

The simulation setup three users' signal is periodic signal 10101010,11001100,00001111 respectively. Sampling a total of 8192 times, 64 bits per sample, sampling 128 bits and bit rate is 2.5 Gb/s. Put the number of sampled per bit divided into four groups, each group has 16 sampling points, considering the transmission distortion factor, get rid of the first four points and the last four points. Average the rest eight values, then every bit signals has only four values. In actual situation, the normalized processing should be done because the amplitude of signal receiving terminal receives will attenuation. The eye diagram of multiplied signal input and the signal after transformed by optical fiber shown in figure 3- (a) and 3- (b) respectively, two eye diagram just distortion on the amplitude and the range of eye diagram reflects the actual signal amplitude.Therefore, the signals' values whose energy fluctuate near 0,0.118m,0.229m and fluctuation amplitude is less than or equal to 0.03m are assigned to 0,1,2 respectively. The normalized value are four values of each bit, which corresponds to the values above of the group a, b, c, d in each bit. We do the judgment according to table 1 after the normalization ,and the signals which are binary can be separated out, then we can obtain the original signals by the zeroing signal generator. In table 2 we make a comparison of the separated signal of each user with the original one, and get a result that the two kinds of signals are coincident, which indicates that the this method of de-multiplex is feasible.

Table 2 The comparison of the signal before multiplexing and after multiplexing

	signal before multiplexing	signal after multiplexing
Use1		User 2		User 3		
b. Simulation Setup

The simulation settings are shown in Figure 4. The three signals are multiplexed through adders, get the absolute value through a absolute signal generator. We use MZM to modulate the electronic signal to a continuous optical wave emitted from the laser whose wavelength is 1550nm, and photoelectrically converted by the optical detector to obtain the multiplexed electrical signal after the transmission through a 50Km optical fiber. Then input this signal to APDCDM demultiplexer, as a result the multiplexed electrical signal is separated into three binary signals, and finally recover the three users' original data by using the zero pulse generator.

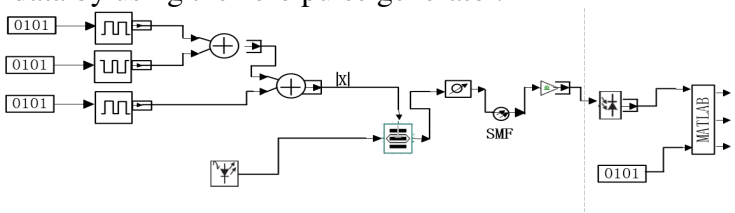

Fig.4 The simulation settings of APDCDM with three users

Result and Discussion

a. Average energy per symbol

The average signal energy per bit can be obtained from the signal waveform by calculating.We work out the signal energy of eight kinds of combinations and and show it in Figure 5.The energy of the signal is calculated as: $E_i = \begin{cases} \frac{n+1}{8n} \times A^2 T_i & n = odd \\ \frac{n+2}{8(n+1)} \times A^2 T_i & n = even \end{cases}$

Where, i = 1,2,3 ... 2^n, n is the number of users, A is the signal amplitude in volt, T_i is duration of the signal. Obtained signal average energy per bit of 8 kinds of combination $E_{everage} = \sum_{i=1}^{8} Ei \div 8 = \frac{2}{24} A^2 Ts$, T_s is the duration of each bit signal.

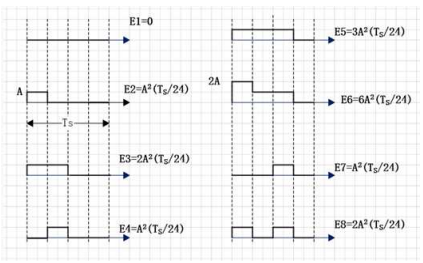

Fig.5 Energy for 8 cases of APDCDM with three users

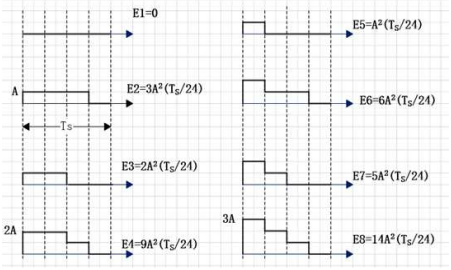

Fig.6 Energy for 8 cases of DCDM with three users

b. Comparison of APDCDM with DCDM

We use the same method to calculate the DCDM energy, and show it in Figure 6 . The average signal energy per bit of the eight kinds of combinations is: $E_{everage} = \sum_{i=1}^{8} Ei \div 8 = \frac{5}{24} A^2 Ts$,Comparing the average energy value DCDM with APDCDM , APDCDM reduce the transmission energy significantly. This solves the problem of DCDM that multiplexed signal energy increases rapidly with the number of users increases. It's obvious that APDCDM can carry more users than DCDM.

Conclusion

This paper propose a multiplex technology which use the bipolar RZ signal to realize duty cycle division multiplexing on the basis of DCDM, that is Absolute Polar Duty Cycle Division Multiplexing(APDCDM). We do the co-simulation by using OptiSystem and Matlab, design a APDCDM optical fiber transmission system of three users, and in the stimulation get a result that the separated signal of each user is consistent with the original one before multiplexing which verifies the viability of apply APDCDM to fiber-optic communication systems. Of course , we have confirmed that because of the introduction of the absolute polar, APDCDM can carry more users than DCDM and has higher utilization of bandwidth. The practical use of this technology still requires further research .

Keywords: target tracking; Camshift; Kalman filter; data fusion; Kim algorithm

Abstract. A tracking algorithm based on improved Camshift and Kalman filter is proposed in this paper to deal with the problems in traditional Camshift algorithm, such as tracking failure under color interference or occlusion. Firstly, the proposed algorithm improves the single color target model and presents a novel target model, which fuses color and motion cues, to enhance the robustness and accuracy of target tracking. And in order to increase the tracking efficiency, the algorithm combines Kalman filter with the improved Camshift algorithm by using Kalman filter to predict the position of the tracking target under color noises and occlusion. The experiment results demonstrate that the proposed algorithm can track the target object accurately and has better robustness.

Introduction

Visual tracking technique is a hot research topic in computer vision and has been widely applied in electronic monitoring system, intelligent traffic management, medicine and military fields. The Meanshift algorithm proposed by the Comaniciu D et al. [1][2] is widely recognized and it has the trait of non-parameters and fast pattern matching. However, the algorithm is not an adaptive mechanism, can not automatically adjust the size of tracking box. Meanwhile, the algorithm does not use the information of moving targets' direction and speed in the process of tracking, the tracking accuracy is low under the complex background and occlusion. Bradski[3] proposed a tracking algorithm based on color histogram--Continuously Adaptive Mean Shift algorithm. This algorithm can automatically adjust the size of the window, accurately track the target, but as with Meanshift algorithm it falls to track the target under color interference or occlusion. Kalman filter is extensively used for tracking in many areas of control theory, signal processing, computer vision and so on. The Kalman filter estimates the state of a dynamic system, even if the precise form of the system is unknown [4].

The Kalman filter theory

Kalman filter is an algorithm of estimating the linear minimum variance of state sequence of a dynamic system, using the state equation and observation equation to describe a dynamic system. In target tracking, the Kalman filter is used for the estimation of an object's location in the current frame, in accordance with the object's locations in the previous frames.

The state equation and observation equation of the system are:

$$X_k = AX_{k-1} + Bu_{k-1} + W_{k-1} \tag{1}$$

$$Z_k = HX_k + V_k \tag{2}$$

Where, X_k and X_{k-1} are state vectors of time k and $k-1$, A is state transition matrix, Bu_{k-1} is external input control, Z_k is the observation vector, the matrix W and V represent the state and the measurement noise with covariances Q and R, respectively.

The process of Kalman filter is divided into two stages: Prediction: includes the state prediction and error covariance prediction; Correction: includes calculating Kalman filter gain coefficients and using the gain coefficients to modify observations and error covariance, for making the correction values are more close to the target's real information.

The improved Camshift algorithm

The color feature is widely used in the process of tracking, for this is easily extracted. Moreover, the variation and complexity of tracking scene may easily lose the target, such as backgrounds with similar color or sudden light changes. If integrating multiple features the algorithm can improve the performance of tracking. Therefore, this paper adopts an improved target model of fusing color and motion information.

The extraction of motion information. This paper uses Kim algorithm to get the target motion information[6], namely, combining frame differential with background subtraction method to effectively extract the target. Supposing $f_{k-1}(x,y)$ and $f_k(x,y)$ are two adjacent frames, $f_b(x,y)$ is background image, calculate the difference between two frames, calculate the difference between current frame and the background image:

$$T_b(x,y)=\begin{cases}1, \left|f_k(x,y)-f_b(x,y)\right|>t_2\\ 0, \left|f_k(x,y)-f_b(x,y)\right|\le t_2\end{cases},\quad T_t(x,y)=\begin{cases}1, \left|f_k(x,y)-f_{k-1}(x,y)\right|>t_1\\ 0, \left|f_k(x,y)-f_{k-1}(x,y)\right|\le t_1\end{cases} \tag{3}$$

Then, calculating target motion template after binarization:

$$M(x,y)=\begin{cases}1, \left|T_k(x,y)\cap T_b(x,y)\right|=1\\ 0, \left|T_k(x,y)\cap T_b(x,y)\right|=0\end{cases} \tag{4}$$

Finally, the images obtained by formula (4) use morphological filter and connectivity analysis, then get motion probability distribution diagram I_m.

The fusion of color and motion information. Assuming that the candidate target is a rectangular area, (x,y) is the coordinates of the area of the pixel in the current frame, the color and motion information are:

$$M_c=\sum_x\sum_y I_c(x,y)\ ,\ M_m=\sum_x\sum_y I_m(x,y) \tag{5}$$

Where $I_c(x,y)$ and $I_m(x,y)$ are position (x,y) pixel values in color and motion probability distribution diagram.

The method of the fusion of color and motion information:

$$M=(1-\beta)M_c+\beta M_m=\sum_{x,y}((1-\beta)I_c(x,y)+\beta I_m(x,y)) \tag{6}$$

Here, M is joint zero moment, $\beta\in[0,1]$ is the weight of motion information, usually take 0.7. This kind of combining color with motion information to establish the target model is more stable and reliable than traditional algorithm which adopted single feature.

Improved Camshift algorithm. The specific process is as follows:

Ⅰ.Firstly, compute zero-order moment and first-order moment:

$$M_{00}=M=\sum_x\sum_y((1-\beta)I_c(x,y)+\beta I_m(x,y)),$$

$$M_{10}=\sum_x\sum_y x((1-\beta)I_c(x,y)+\beta I_m(x,y)),\quad M_{01}=\sum_x\sum_y y((1-\beta)I_c(x,y)+\beta I_m(x,y)) \tag{7}$$

Ⅱ.Calculate the centroid position of the search window:

$$x_1=\frac{M_{10}}{M_{00}}\ ,\ y_1=\frac{M_{01}}{M_{00}} \tag{8}$$

Then, locate the center of the rectangular area $C(x_1,y_1)$, and change the number of iterations $n=n_1+1$.

Ⅲ.If $\|C_1-C_0\|<\varepsilon$ or $n_1>n_0$ stop iteration, update the target position C_1; otherwise, take $C_0=C_1$, return to step Ⅰ.

Combining Kalman filter with improved Camshift algorithm

The Camshift algorithm is vulnerable to full occlusion in successive frames, because the iteration is initialized by using the results obtained in the previous iteration. Therefore, the Kalman filter can be used for full occlusion detection. If the desired object, during overlapping, then its location and speed can be predicted using the Kalman filter. The specific algorithm steps are as follows:

Ⅰ.Read the first frame, extract target manually, obtain the initial state of target, get the target model according to section 2.1;

Ⅱ.Initialize the parameters of Kalman filter, and calculate the predicted position of the object;

Ⅲ.Calculate the optimal target location under Camshift algorithm;

Ⅳ.Determine whether color interference or severe occlusion: if not, using Camshift algorithm optimal location as observed value to update Kalman filter; if yes, using Kalman filter predicted location as observed value to update Kalman filter;

Ⅴ.Read the next frame, return to step Ⅱ.

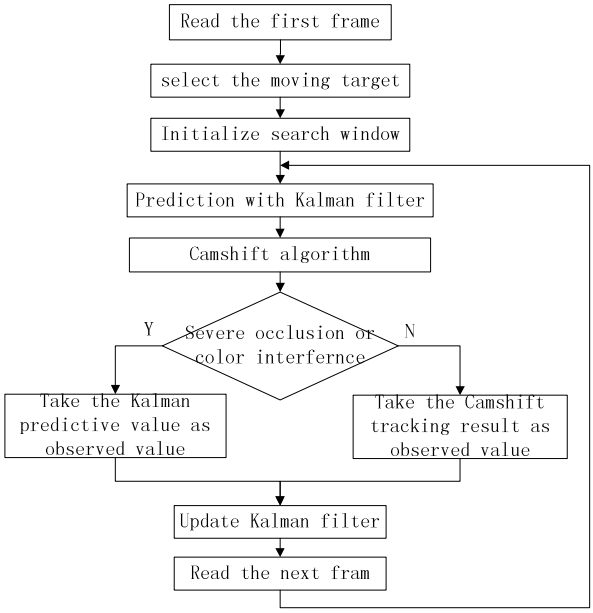

Fig.1 Flowchart of combining Kalman filter with improved Camshift

Experimental results

In order to verify the performance of the algorithm, we did the experiments respectively under the condition of the similar color interference and occlusion. Fig.2 shows the tracking results under similarly colored backgrounds. The traditional Camshift algorithm will gradually lose target, the search window stays on the road, while the proposed algorithm can track the target very well.

(b) Improved algorithm

Fig. 3 Tracking results in the server occlusion

Conclusion

This paper presents a tracking algorithm based on improved Camshift and Kalman filter. Firstly, the algorithm improves the traditional target model and presents a novel target model, which fuses color and motion cues. Then, the algorithm combines Kalman filter with improved Camshift algorithm and uses Kalman filter to predict the position of the target when color noises and occlusion. The new approach can remove the interference of similar color and overcome the occlusion problem in the process of tracking. The experiment results demonstrate the proposed algorithm can track the target accurately and has a better robustness to occlusion.

Keywords: Cognitive radio; sequential spectrum sensing; sensing sequence.

Abstract. In this paper, the problem of maximizing the average throughput of a CRN through setting proper sensing sequences is investigated. In order to find the optimal sensing matrix, we obtain the spectrum sensing sequence. The structure of the proposed scheme is discussed in detail.

Introduction

Emerging new wireless applications and higher data rates rate have incredibly increased the demand for accessing to spectrum in the past ten years. Though the existing spectrum resources seem to not meet the ever-growing demand, many investigations reveal that the spectrum is grossly under-utilized in time, space, and other dimensions [1]. In order to alleviate the shortage of spectrum, cognitive radio (CR) concept, as a potential communication paradigm, has been introduced to improve spectrum efficiency by allowing low-priority secondary users (SUs) to opportunistically exploit the unused licensed spectrums of high-priority primary users (PUs), called white spaces, in a somewhat intelligent manner [2]. To protect primary users (PUs) from the harmful interference, CRs have to be capable of sensing the radio spectrum, learning and adapting to the wireless environment.

The rest of this paper is organized as follows. In Section II, we describe the system model. In Section III, the example and analysis are then presented. Finally, the paper is concluded in Section IV.

System Model

We assume a time-slotted CRN with N_s SUs, which attempt to opportunistically transmit on the channels dedicated to the N_p PUs. The SU exploits narrow-band spectrum sensing that is, it senses only one spectrum at a time. The SUs are synchronous in time-slots with other SUs as well as the PUs. The PUs start their transmissions only at the beginning of the slot whenever they have data for transmissions [3]. Therefore, in order to find the transmission opportunities appropriately and to protect the PUs from a harmful interference, the SUs sense the channels at the beginning of each time-slot, by which the channels can be established as occupied or vacant. We assume that the SU always has packets to transmit, that means, the SU starts its transmission when an opportunity is found. Each SU senses the channels according to its SS sequentially, i.e., the SU senses the channel from the top of the sensing sequence, and then starts sensing the second channel if and only if the first channel is sensed occupied. This procedure will be continued until a transmission opportunity is found.

In order to switch to a new channel, a secondary device needs a specific and constant time duration τ_{ho} to prepare its sensing circuitry. After sensing $K-1$ occupied channels, if the SU finds the K th channel free, the user will transmit data on that channel until the end of the slot. In this case, the wasted time length, i.e., the time spent on the sensing and handover, is equal to $(\tau+\tau_{ho})(K-1)+\tau$. The SUs do not have the adaptive modulation and coding capability; hence they transmit with a constant rate, R during the transmission section.

Then, we have [3]

$$B_k = Re_k = R[1-\frac{(\tau+\tau_{ho})(K-1)+\tau}{T}] \quad (1)$$

where B_k is the average throughput of the SU if the k th channel of its SS is chosen for the transmission. Apparenttly, we can see $B_k > B_j$, if $j > k$ .The objective of every SU is to find a good sensing sequence, which can make the transmission faster.

Here we define a coordinate matrix M with the dimensions of $N_p \times N_s$, where the i th row contains the SS dedicated to the i th SU [4]. The coordinate matrix M contains N_s rows because of N_s SUs. Every row contains N_p elements.

$$M = \begin{bmatrix} SS_1 \\ \vdots \\ SS_{Ns} \end{bmatrix} = [S_{i,j}] = \begin{bmatrix} S_{1,1} & \cdots & S_{1,j-1} & S_{1,j} \cdots S_{1,N_p} \\ & & & \\ S_{N_s,1} & & S_{N_s,j-1} & S_{N_s,j} \cdots S_{N_s,N_p} \end{bmatrix}$$

For the network throughput evaluation, we note that for each spectrum $S_{i,j}$ two possible cases might occur. First, the $S_{i,j}$ th spectrum has been sensed by some SUs in their previous mini-slots (the mini-slots before j th mini-slot). In this case, regardless of the presence or the absence of the PU, the spectrum is occupied (as we assumed error-free sensing in this section). That is, the SU which senses this channel at the first time will transmit if the spectrum is idle. The second case is that the spectrum is sensed at the j th mini-slot by i th SU at the first time. Hence, the occupation probability of this channel only depends on the PU activity. From the above discussion, the repetition of a spectrum in the M when assuming error-free case does not offer any benefit to the CRN throughput.

By the above discussion, the available probability [5] of i th SU for the $S_{i,j}$ th spectrum is expressed by,

$$P_{i,j}^{*} = \begin{cases} 0 \\ P_{0,S_{i,j}} \end{cases} \quad (2)$$

Where $P_{0,S_{i,j}}$ is he absence probability of the $S_{i,j}$ th PU.

However, we can see that the i th SU transmits at the $S_{i,j}$ th spectrum when the spectrums in their previous mini-slots have already occupied.

According to the conditional probability, we have

$$P_{i,j} = P_{i,j}^{*} \prod_{l=1}^{j} \left(1 - P_{0,S_{i,l}}\right) \quad (3)$$

Then, the final available probability is expressed by,

$$P_{i,j} = \begin{cases} 0 \\ P_{0,S_{i,j}} \prod_{l=1}^{j} \left(1 - P_{0,S_{i,l}}\right) \end{cases} \quad (4)$$

By the above discussion, the average throughput of the CRN is easily computed as,

$$Q = \sum_{j=1}^{N_p} \left(\sum_{i=1}^{N_s} P_{0,S_{i,j}} \prod_{l=1}^{j} \left(1 - P_{0,S_{i,l}}\right) \right) B_j \quad (5)$$

Where B_j is defined in (1)

Now, the optimal M is found by solving the following:

$$M^* = \arg\max Q \tag{6}$$

Example and Analysis

In this section, the performances of the proposed schemes are evaluated and compared by the analytical results and simulations considering the effects of different parameters introduced throughout the paper. The values of parameters used for the numerical evaluation are given in Table 1.

Table 1. Simulations Parameters

Parameters	Description	Value
T	Time-slot duration	200ms
τ_{ho}	Requires time for handover	0.1ms
N_p	Number of PUs	5
N_s	Number of SUs	3

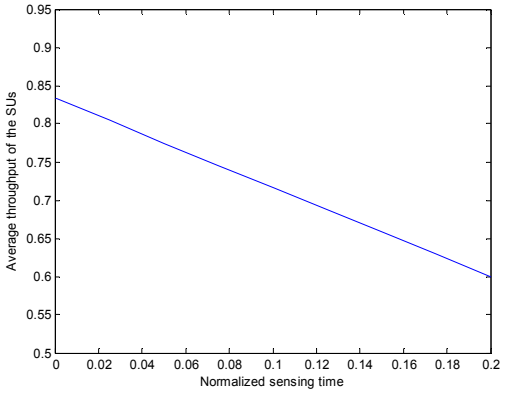

Figure 1 Average throughput against the normalized sensing time

Figure 1 validates our analysis and depicts the average throughput of the SUs against the normalized sensing time for an error-free sensing scheme. For the optimal M , the simulation result is provided. As realized, the average throughput linearly decreases by the normalized sensing time. This is owing to the fact that for the error-free case, there exists no error in the detection scheme and thus while the increase of sensing time does not have any positive effect on the correct detection, it linearly reduces the transmission time.

Conclusion

In this paper, a novel intelligent sensing matrix setting scheme has been proposed, which maximizes the average secondary users' throughput. As a future work, we aim to extend the proposed system by modeling the impact of error and latency on the throughput estimator block.

Keywords: wavelet; de-noising; genetic algorithm; threshold

Abstract. The central step of de-noising in wavelet domain is the threshold selection. To get the best de-noising result, the threshold should be selected according to the noisy observation. This paper presents a genetic adaptive threshold method, which gets the optimum threshold in the sense of least MSE by using an estimation function of the signals' MSE function. The simulation results with standard wavelet test signals shows that the operation speed of the proposed method four times the traditional continuous searching algorithm, moreover, the optimum threshold calculated is more accurate and reasonable.

Introduction

Wavelet transform could decompose noisy signal into several scales. Since signal and noise have different features on different scales, such a property can be used for separating the signal from noise. According to this theory, wavelet transform has been used in many fields for de-noising process [1-8].

The wavelet transform has primary properties such as compression or sparse which means that wavelet transforms of noisy signals tend to be sparse. Due to the fact that the wavelet transform of a noisy signal is a linear combination of the wavelet transform of the noise and the original signal, the noise energy can be suppressed significantly with a suitable threshold while the main signal features can be preserved. The functionality of the de-noising process is due to the threshold value and the thresholding rule. Hard thresholding function is a basic ones introduced by Donoho[8]. The coefficients less than the threshold value are set to zero and others remain unchanged. Therefore, the optimum threshold value selection plays an important role in de-noising process. Reference [1] presented a thresholding function, $t=\sigma\sqrt{2\log N}$, By using this equation, it is easy to get the threshold value of the coefficients of the orthogonal wavelet, however the method has limitation because the optimum threshold value varies with the total number of samples (for example, $N=4096$, $t\approx 4.079\sigma$; $N=1024$, $t\approx 3.723\sigma$). It is obvious that the threshold value get from the previous function is not optimum, and the best result of de-noising can not attained as well. For the noisy signal which contain Gaussian white noise, 99.74% noise are reduction if the threshold value is set as the next formula: $t=3\sigma$, where t is the threshold value and σ is Gaussian white noise standard deviation, furthermore, a suitable constant multiplied by σ could be the best threshold. Reference [7] proposed an approximation value of the mean square function, and the optimum threshold value can be achieved by choosing suitable parameter c, which was used in many applications. However, it is needed too large amount computation for the approximation value so that the process is useless in practice and almost all the practical application choose a random value between [2,3] instead.

Since it is difficult to get the optimum threshold value proposed in reference [7] by using the normal method used for optimum searching, this paper presents a genetic adaptive algorithm which could quickly find the best threshold value according to the objective observed noisy signal.

Wavelet hard thresholding

The signal's singular structures can be represented with the wavelet coefficients. The coefficients of signal and noise have different characters on different decomposition scales. The hard thresholding de-noising in the wavelet domain can be summarized as follows. (1) The noisy signal is decomposed in the wavelet domain; (2) The coefficients which below threshold are set to zero and others remain unchanged; (3) Applying inverse wavelet transform on modified coefficients to reconstruct the signal.

MSE(mean square error) function presents the difference between the real signal and the estimation data. Otherwise, in practical application, the real signal is always unknown. Therefore, the estimation of MSE is needed, and the minimum of the estimation can be used as the criterion for optimum threshold value searching. Reference [8] proposed a MSE approximation function,

$$F(c) \approx Error(c) = 2[\sigma^2 - \frac{k}{2erf(c)N}\int_{-c\sigma}^{c\sigma} x^2 \frac{e^{-x^2/(2\sigma^2)}}{\sqrt{2\pi}\sigma}dx] - E[\hat{W}_f^2] \tag{1}$$

$x \sim N(0,\sigma^2)$, $erf(c) = \frac{1}{\sqrt{2\pi}}\int_0^c e^{-y^2/2}dy$,Obviously, $2erf(c) \approx k/N$, $E[\hat{W}_f^2]$ in equation (1) is the residual wavelet coefficients after de-noising with the threshold $c\sigma$, and k wavelet coefficients are set to zero after de-noising, N is the quantity of samples. It is obvious that the integration process can not expressed by basic functions. Therefore, it is difficult to find optimum threshold value using normal algorithms. The minimum of the MSE correspond with the threshold parameter c which is a approximation of the optimum threshold value parameter. The algorithm above must calculate all the function value correspond with every discrete point in an interval of $c \in [1,6]$. Because of the integrate process need too large amount computations, a random number often be selected at interval [2,3] instead. Therefore, advanced algorithm must be found for searching the optimum threshold value.

Genetic algorithm can be applied for the formula (1) calculation procession which first selecting suitable population and generation, then using bound searching for optimal threshold value instead of continuous searching. In order to reduce the computation complexity and speed up searching process, this paper improves the traditional genetic algorithm. The procedure of new algorithm can be divided into the following steps.

Step 1: Deciding the encoding and decoding method. In this paper, L bits of binary strings are used for encoding and decoding. The bit of the binary is called gene, with a value of 1 or 0. The string of the binary is called chromosome. Suppose the minimum and maximum of c are $c_{\min}$ and $c_{\max}$, respectively, which are calculated according to Equation (1). The accuracy δ can be calculated by formula :

$$\delta = \frac{c_{\max} - c_{\min}}{2^L - 1} \tag{2}$$

in which $c_{\max} = 6, c_{\min} = 1$, suppose $L = 13$, then the accuracy $\delta = 0.00061$. Encode c into a binary code with bits of L, and c can be decoded from the binary code into a decimal number by equation (3):

$$c = c_{\min} + (\sum_{i=1}^{L} b_i 2^{i-1})\delta \tag{3}$$

in which b_i is the value of the i th bit of c in the binary style.

Step 2: Calculating the fitness of every individual of the population. Based on equation (1),

$$F(c) \approx Error(c) = 2\sigma^2 - (\frac{2k}{N\sigma}\frac{\int_0^{c\sigma} x^2 e^{-x^2/(2\sigma^2)}dx}{\int_0^c e^{-y^2/2}dy} + E[(W_f(c))^2]) \tag{4}$$

with $E[(W_f(c))^2] = E[(W_f .* |W_f > c\sigma|)^2]$. The fitness function of the genetic algorithm is defined as follows:

$$f=\frac{2k}{N\sigma}\frac{\int_0^{c\sigma}x^2e^{-x^2/(2\sigma^2)}dx}{\int_0^{c}e^{-y^2/2}dy}+E[(W_f(c))^2] \tag{5}$$

When the MSE Error(c) is at minimum, the fitness function (5) achieves the maximum. Then c is considered as the optimum threshold parameter and the optimum threshold value: $t=c\sigma$.

Step 3: Selecting the individuals in the current generation. Based on Equation (6) the selection probability p_i of the i th individual is determined. Dominant individuals are selected for genetic operation according to the selection strategy. In this paper, the roulette wheel selection scheme is used for selecting the individuals as parents.

$$p_i=\frac{f_i}{\sum f_i} \tag{6}$$

Step 4: selecting p_r percent elite chromosome to directly copied, and each chromosome copies n times, then the quantity of individual after reproduce is : $M_N=M*p_r*n$ (7)

in which M is the quantity of individual in current population. The next process is mutation. The probability P_m of mutation is showing as follows:

$$P_m=p_m*\frac{N-k}{N} \tag{8}$$

in which N is the length of a chromosome and $k=round(\log(10(c_{\max}-c_{\min})))$.

Step 5: updating the population. Replace $M*p_r$ chromosome by optimum chromosome in order to remain the quantity of population unchanged.

Parameters of the binary coding genetic algorithm are determined as follows: the population size N_s=40, the length of chromosome L=13, the copy times n=10, probability of mutation p_m=0.1, the update percent fat=0.2.

It is obvious that large computation concentrate on the calculating the chromosome's fitness functions. This process needs N_s times computation and each chromosome in every generation also need computation their fitness function which computation times is N_s*p_m*n. Therefore, all the operation times can be calculated as follows:

$$N=(N_s+N_s*p_m*n)*G \tag{9}$$

Test results

In order to prove the effect of the proposed algorithm, we designed MATLAB codes to carry out the hard threshold de-noising computation. By testing on the noisy signals which including wavelet noise test data, we can prove the accuracy and effective of the genetic adaptive algorithm. All computation in this paper is carried on by MATLAB codes in Microsoft Windows 7, 64-bits. The processor in the computer is an Intel Core i3 with max speed of 2GHz and 4 GB memory.

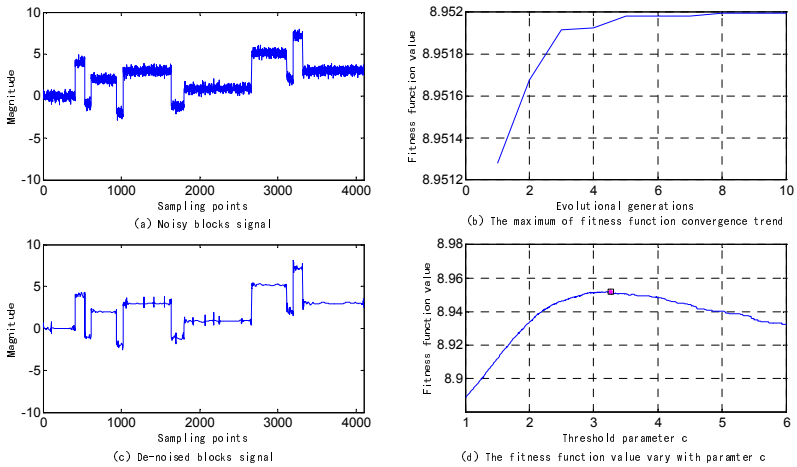

Figure 1. Experiment used blocks signal

The first experiment used 'blocks' signal, figure 1(a) shows the noisy signal which is a linear combination of 'blocks' and Gaussian white noise; Figure 1(b) shows the maximum of fitness function convergence trend with evolutional generations, from this figure it can be seen that the fitness is convergent when the evolutional generation $g > 8$, and the maximum of the fitness is 8.9520, the optimum parameter $c = 3.2628$; Figure 1(c) shows the result of genetic adaptive hard thresholding de-noising; Figure 1(d) shows the chart of fitness function's value using continuous searching algorithm, the searching step is 0.001, interval is [1,6], the maximum of fitness is 8.9520, and the optimum threshold value c=3.262. In this figure, the maximum of fitness calculated by genetic adaptive algorithm is marked with "□" and by continuous algorithm is marked with "*". The two marks almost overlapped at the same point, but the value calculated with genetic adaptive algorithm is more accurate. Furthermore, the time cost of continuous searching is t=14.76s and genetic algorithm time cost is t= 3.58s.

The test data of experiment 2 is 'bumps'; the experiment 3 using 'heavy sine' signal. The compare of traditional continuous searching algorithm and genetic one of each experiment are showing as tables 1.

Table 1. Comparison of two methods

Methods	blocks			bumps			heavy sine		
	Maximum	parameter c	Time (s)	Maximum	parameter c	Time (s)	Maximum	parameter c	Time (s)
Continuous	8.9520	3.262	14.76	3.4323	3.427	14.78	9.6879	3.720	14.84
Genetic adaptive	8.9520	3.2628	3.58	3.4323	3.4264	3.62	9.6879	3.7201	3.67

Conclusion

The paper proposed a fast calculation algorithm of the optimum threshold parameter at the means of least MSE, and the theory and practice proved it can be improve the calculation speed more than 4 times without loss accuracy. The traditional algorithm is random selecting a value between [3,4], the algorithm proposed in this paper solve the problem which can be adaptive selecting the optimum threshold parameter c according practical conditions.

Keywords: ND5 protein Sequences; Similarity; Graphical Representation; L/L matrix; Leading Eigenvalue.

Abstract. Based on the helix and β-sheet and the β-turn conformational parameters, P_α and P_β and P_t, of the 20 amino acids, we propose a new 3D graphical representation of protein sequence without circuit or degeneracy, which may reflect the innate structure of the protein sequence. Then the numerical characterizations of protein graphs, the leading eigenvalues of the L/L matrices associated with the graphical curves for protein sequences, was utilized as descriptors to analyze the similarity/dissimilarity of the nine ND5 protein sequences.

Introduction

In recent years, some researchers proposed many methods to analyze the huge amounts of gene data. The graphical representation method initiated in 1983 by Hamori[1] is one of those methods. From Hamori, Graphical techniques became a very powerful tool for the visualization and analysis of DNA sequences[2-16]. However the graphical representation of protein sequence emerges only recently, and some representations are outlined[17-32].The emergence of graphical representations of proteins was delayed because it is more perplexed to deal with biological strings built on a 20-letter alphabet (representing the 20 natural amino acids) than to deal with biological strings built from only four letters (representing DNA or RNA). Moreover, Most of existing 2D and 3D graphical representations of proteins involve the arbitrary assignment of amino acids to vertices of graphs or geometrical objects considered. Following previous work, Yao et al.[27] outlined a 2D graphical representation for proteins based on the physicochemical properties of amino acids. But there exists circuit or degeneracy in Yao's 2D graphical representation for proteins which lead to losing much biological information due to overlapping and crossing of the curve with itself. In order to avoid deficiency in Yao's work, Wen et al.[28] proposed another 2D graphical representation for proteins based on the physicochemical properties of amino acids. But until now, just few 3D graphical representation of protein sequences was proposed[24,29-31].

In this letter, a 3D graphical representation of protein sequence was outlined utilizing the helix and β-sheet and the β-turn conformational parameters, P_α and P_β [33,34] and P_t [35], of the 20 amino acids, which may reflect the innate structure of the protein sequences. Significantly, our graphical representation avoids the degeneracy of graphical curve. With this graphical representation, we consider the numerical characterization of mutations and analyze the similarities among sequences belonging to nine ND5 (NADH dehydrogenase sub unit 5) proteins: human (Homo sapiens, YP 003024036), gorilla(Gorilla gorilla, NP 008222), common chimpanzee (Pan troglodytes, NP 008196), pigmy chimpanzee(Pan paniscus, NP 008209), fin whale(Balenoptera physalus, NP 006899), blue whale(Balenoptera musculus, NP 007066), rat(Rattus norvegicus, AP 004902), mouse(Musmusculus, NP 904338), and opossum(Didelphis virginiana, NP 007105).

3D graphical representation of protein sequence

The helix and β-sheet conformational parameters, P_α and P_β, of the 20 amino acids have been quantitatively determined from a statistical analysis of 15 proteins with known conformation[33,34].

Later, the β-turn conformational parameters, P_t, of the 20 amino acids was quantitatively determined from a statistical analysis of 12 proteins with known conformation[35]. In this paper, these three protein conformational parameters, P_α and P_β and P_t, of the 20 amino acids was selected as the basic to construct protein map. P_α and P_β and P_t values we have adopted listed in Table 1. From Table 1, we can find that the average of P_α and P_β and P_t values, $<P_\alpha>$and$<P_\beta>$and$<P_t>$, of 20 amino acids is 1.0005 and 1.0405 and 0.9655 respectively. If the point (1.0005,1.0405,0) is taken as the origin, there is 20 special vectors respecting the 20 amino acids in 3D Cartesian coordinates. The numerical values in the last three columns of Table 2 are the *x* and the *y* and the *z* coordinates for 20 amino acids along the *x*-axis with respect to P_α and along the *y*-axis with respect to P_β and along the *z*-axis with respect to P_t. From Table 1, each amino acid can be numerically characterized by a unique special vector. The points in the 3D graphical representation are obtained by the sum of vectors representing amino acids in the sequence. For example, given a protein sequence with *N* amino acids $S = s_1, s_2, \cdots, s_N$, inspect it by stepping one amino acid at a time. For the step *i* (i = 1, 2,… , N), the point $P_i(x_i, y_i, z_i)$ can be constructed as follow:

$$x_i = \sum_{k=1}^{i} S_k^1, y_i = \sum_{k=1}^{i} S_k^2, z_i = \sum_{k=1}^{i} S_k^3$$

where $S_k^j \left(j = 1,2,3\right)$ represents the *j*-th component of the vector corresponding to S_k. When i from 1 to N, we have points $P_1, P_2, \cdots, P_N$. Connecting the adjacent points, we can obtain the protein curve. Our graphical representation has no circuit or degeneracy. We can easily find that

there is no circuit or degeneracy in our model. That's to say, no circuit exist in the graphical representation. The graphical curve and protein sequence follow a one-to-one correspondence, and sequence alignment can be done by simply identifying similar segments of the graph from our method. In addition, the protein sequence can be recovered from its graph mathematically without loss of biological information. If the point (1.0005,0,0.9655) and if the point (0,1.0405,0.9655) is taken as the origin, following the method mentioned above, we can get another two graphical curves for the same protein sequence. We called these three graphical curve as P_t-curve and P_β-curve and P_α-curve, respectively.

In Figure 1, we illustrate the dynamic 3D graphical representations of ND5 proteins for nine different species. Comparing the curves, we can find that the curves of the ND5 proteins of human, gorilla, common chimpanzee, and pigmy chimpanzee are more similar although gorilla is somewhat different, and the ND5 protein graphs are more similar for (fin whale, blue whale) and (rat, mouse) too. In addition, we find ND5 protein graph of opossum is obviously different from the other species. And their similarities/dissimilarities are consistent with the known fact of evolution. [27,28,36-38]

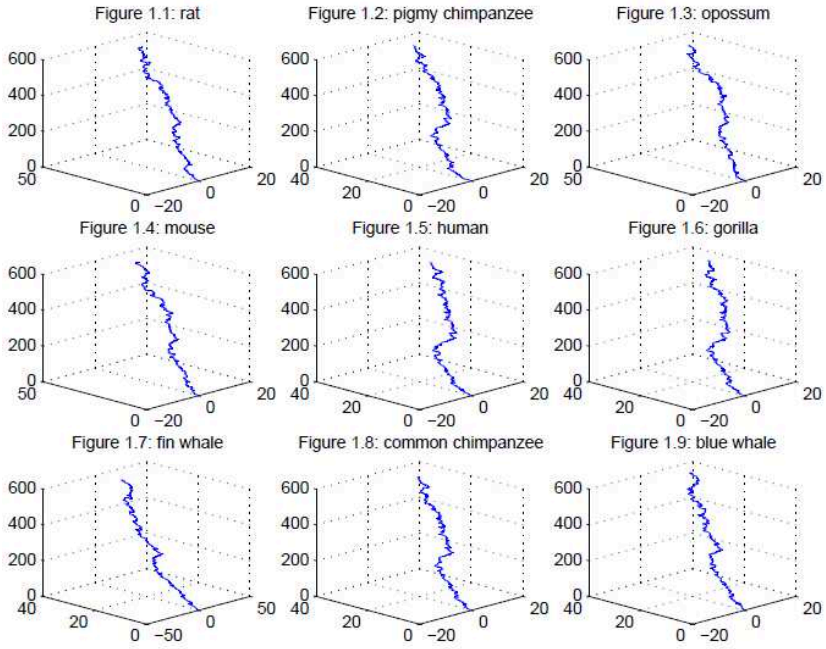

Fig. 1. The P_t-curve of nine ND5 proteins

Numerical characterization of protein sequence

In this section, we will illustrate the numerical characterization of graphical curve which facilitates quantitative comparisons of sequences. Mathematical invariants can be used to characterize the graphical curve. First we transform the graphical curve into a matrix to represent a sequence, then we use some of matrix invariants[6-7,9-16] as descriptors of protein sequence, such as the eigenvalue of constructed matrices. Especially, the leading eigenvalue of matrices is widely used in the comparison of sequences. In this report, the numerical characterization of the graphical curve is given by the matrix: L/L matrix.

The L/L matrix is the symmetric matrix whose off-diagonal elements are defined as a quotient of the Euclidean distance between two vertices of the zigzag curve and the sum of geometrical lengths of edges between the two vertices. By definition all diagonal entries are zero. In other words

$$l_{i,j} = \begin{cases} d_{i,j} / \sum_{k=i}^{j-1} d_{k,k+1} & if\ i \neq j \\ 0 & if\ i = j \end{cases}$$

We will characterize the protein sequences belonging to nine ND5 proteins by means of the leading eigenvalue of the L/L matrix. We list the leading eigenvalues of the L/L matrices associated

with three graphical curves, P_t-curve and P_β-curve and P_α-curve, representing each of the protein sequences in Table 3. The smallest magnitude of the leading eigenvalues is found for Opossum except for the P_β-curve.

Table 3: The leading eigenvalues of the L/L matrices associated with three graphical curves, P_t-curve and P_β-curve and P_α-curve

Species	λ for P_α-curve	λ for P_β-curve	λ for P_t-curve
human	527.618009	534.640631	536.241321
common chimpanzee	527.216431	535.674423	536.68723
pigmy chimpanzee	526.747668	535.455882	535.870302
gorilla	527.394065	534.894326	535.282623
fin whale	530.589867	539.041219	536.535591
blue whale	530.522835	539.519108	537.854552
mouse	528.001379	541.115469	538.310286
rat	530.359992	543.240098	541.283399
opossum	524.089115	536.40529	532.712324

Similarities/dissimilarities of protein sequences

Comparison of similarities/dissimilarities is the essential motivation of graphical representation. Here we also illustrate the use of our quantitative characterization of the protein sequences with an examination of similarities/dissimilarities among nine ND5 proteins. We represent the sequences with the corresponding 3-component vectors. Moreover, the leading eigenvalues can be normalized as mentioned above. The analysis of similarity among protein sequences represented by the 3-component vectors is based on the assumption that two protein sequences are similar if the corresponding 3-component vectors point to a similar direction in the 3D space and have similar magnitudes. The similarity/dissimilarity between these two vectors can be measured by calculating the Euclidean distance between their end points. Clearly, the smaller is the Euclidean distance the more similar are the two protein sequences.

Now we construct a 3-component vector consisting of the normalized leading eigenvalues $(\lambda_1 / N, \lambda_2 / N, \lambda_3 / N)$ of the L/L matrices associated with three essentially different graphical curves for protein sequences, where N represents the length of the protein sequence . In Table 4, we list the similarity/dissimilarity matrix for the protein sequences among nine ND5 proteins based on the Euclidean distances between the end points of the 3-component vectors. Observing from Table 4, we find that the proteins of human, gorilla, common chimpanzee, and pigmy chimpanzee are more similar with each other, and the proteins of fin whale-blue whale and rat-mouse are very similar. On the other hand, the opossum(the most remote species from the remaining mammals) is dissimilar to others among the six species except rat and mouse. So we think that the results of Table 4 about the similarity are consistent to the known fact of evolution[27,28,36-38].

Conclusion

On the basis of the helix and β-sheet and the β-turn conformational parameters, P_α and P_β and P_t, of the 20 amino acids, a new 3D graphical representation of protein sequence was outlined. The advantage of our method is that it allows visual inspection of data, helping in recognizing major similarities among different proteins, but also avoids the some loss of information of proteins. Then we get the numerical characterization of graphical curve, which facilitates the similarity analysis of protein sequence. The method we proposed is more simple, convenient, visible and the result based on our method well coincide with the real evolutionary relationship among these nine species.

Table 4: The similarity/dissimilarity matrix for the nine ND5 proteins based on the Euclidean distances between the end points of the 3-component vectors which consists with the normalized leading eigenvalues of the L/L matrices associated with three graphical curves, P_t-curve and P_β-curve and P_α-curve.

Keywords: Feature refining, object tracking, texture feature, adaptive learning rate.

Abstract. A novel adaptive image feature reduction approach for object tracking using vectorized texture feature is proposed in this paper. Our contributions are three-fold: 1) a statistical discriminative appearance model using texture feature was proposed. 2) Majority of dimensions of the features are removed by judging their errors of the chosen distribution model. The remaining dimensions are most discriminative ones for classification task. The dimension reduction has advantages of reducing the computational cost in classification stage. 3) An adaptive learning rate was proposed to handle drifts caused by long term occlusion. Preliminary experimental results are satisfactory and compared to state-of-the-art object tracking methods.

Introduction

Nowadays, as cameras with video recording capability are so widely used, object tracking draws much attention from researchers. Object tracking locates object position in each frame and output its trajectory for further analysis. [1] Despite many methods have been proposed, the topic remains challenging since the target object keeps changing its appearance in some degree. Occlusion, Scaling and changes of illumination/intensity may lead to the appearance variation which causes a target drift during long term tracking. Moreover, as for mobile cameras, using background subtraction to find out the moving object is almost impossible. Based on the classification models, most tracking methods are categorized into either generative or discriminative. The discriminative tracking methods mathematically model the boundary and distance between target object and backgrounds in feature space. The problem is generally formulated as a binary classification which separates the target object from the background in each frame, which is also called "tracking by detection". The generative tracking models, on the other hand, build up the model of the object class merely using object patches (positive samples). The tracker tries to find out the patch in current frame that has highest similarity to the appearance model. Features along with metric/similarity measure are defined according to specific settings and applications.

In this paper, we adopted general discriminative tracking framework and proposed a simple yet feasible tracking method based on naïve Bayesian classifier. Our main contribution is that we proposed dimension reduction algorithm for vectorized features during training stage which enlarge inter-class distance and reduce influence of large variance in each dimension. An adaptive learning rate was proposed to handle drifts caused by long term occlusion.

Tracking Using Dimension-Reduced Vectorized Feature

Our tracking method shares similar framework with multiple instance learning (MIL)[2]. A general tracking methods consists with three main components: 1) appearance model. 2) motion model and 3)tracking model. The focus of this paper is on improving the appearance model which describes the target object and correctly adapts its changes in long term tracking. For the reasons that object in tracking task is usually dominated by one to three textures. Hence, we employ texture feature instead of haar-like features in MIL which has advantages in detecting contrast of bulks.

In order to reduce the influence of less distinguishing dimension, dimensions of features should be reduced by discarding indiscriminative dimensions and assigned with different weights. The

advantages of this process are obvious: 1) the computational cost in classification stage significantly reduced. 2) not only variance of samples within same class is reduced, but also boundaries between classes become clear. When dimension of feature vector is become low, the numbers of samples provided for training an appearance model decreases exponentially leading to a significant reduction of computational cost. Thus, we defined weights for remaining dimensions with inverse proportion of errors and discard the trivial dimensions. The definition is given as follows:

$$w_j = \begin{cases} b * e^{-c \bullet Err_j} & if \ \ c \bullet Err_j \le T \\ 0 \text{ and } j \text{ dimension discarded} & if \ \ c \bullet Err_j > T \end{cases} \tag{1}$$

where

$$Err_j = \sum_{i=1}^{2N} \left| y^i - p(x_j^i \mid \vec{\alpha}_j) \right|^2$$

$$j \in \{1, 2, ..., M\}$$

The $\overrightarrow{Err}$ is given by least square loss which measures how much the training data is different from an assumed distribution. The ***c*** and ***b*** are normalization factors for $\overrightarrow{Err}$ and $\vec{w}$ respectively. ***T*** is the predefined threshold for filtering dimensions. The empirical value for ***T*** is 0.08 throughout our experiments, which keeps around 15% of the dimensions and discarded other.(Fig.1 shows how the dimension reduction affects the image quality) y^i is the labeled sign denoting which class the $\vec{x}^i$ belongs to. In our case, object patches and backgrounds patches are defined into two classes which assigned 1 and 0 respective. Parameters $\vec{\alpha}$ characterize the chosen statistical model $p(\bullet \mid \vec{\alpha}_j)$. The function $p(\bullet \mid \vec{\alpha}_j)$ outputs a quantitative value, which is within a range of $[0,1]$, rather than a qualitative value. It provides us more flexibility in defining similarity. After this preprocess, ***M***, the number of dimension of feature, is reduced to $M' = \dim(\vec{w})$.

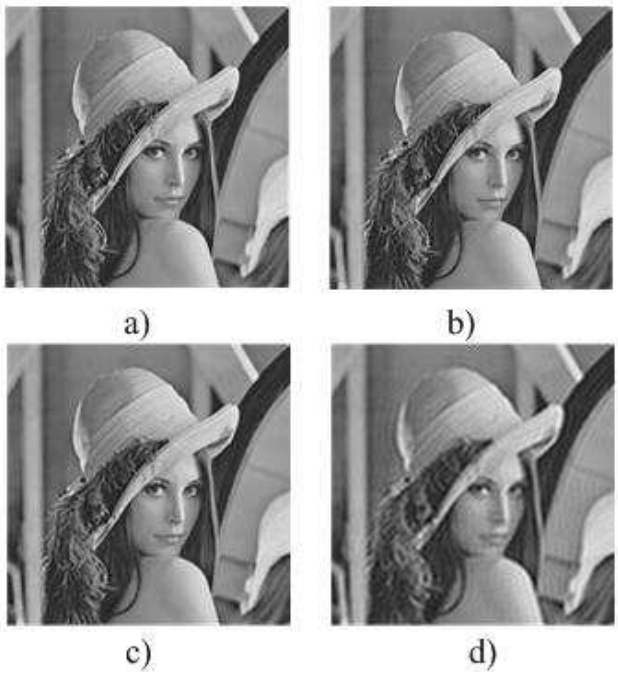

Figure 1. Reconstruction of image with percentage of dimensions shows how the dimension reduction affects the image quality: a) original image, b) reconstructed from remaining 16% dimension, c) reconstructed from remaining 6.25% dimension, d) reconstructed from remaining 2.25% dimension.

Experimental Results

The proposed method was tested on some common testing video clips from Babenko's dataset [4] and CAVIAR dataset. Target objects in these video clips experienced various non-rigid appearance changes including intensity variations, occlusions, rotations and cluttering. These non-rigid changes are considered challenging for object tracking. The dimension of feature vectors is reduced to around 15% of the original size for all the experiments. The 15% reduction rate is almost the highest that we could restore the image without noticeable visual quality loss.

Fig.2 shows the tracking results on 'sylv' video clip from Babenko's dataset. The target in 'sylv' experienced scaling and rotations. Moreover, the video clip contains more than 1300 frames, which is very long for an experiment. Test on this clip is very satisfactory. Tracker is able to track the target steadily and closely follow the ground truth locations.

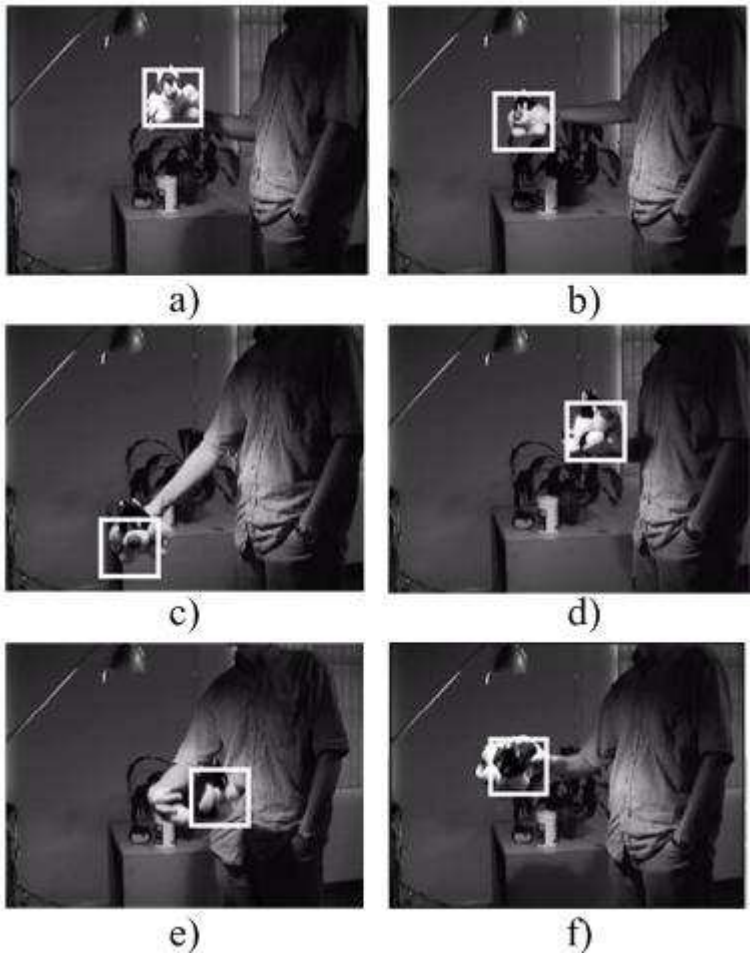

Figure 2. Snapshots of results on 'sylv' video clip. From a) to f) are frame #1 #222 #447 #535 # 1075 and #1165.

Conclusion

In this paper, we proposed a novel technique to refine vectorized texture features and an adaptive learning rate for appearance model in object tracking. Dimensions of feature vectors are selected and assigned with different weights according to the training errors. The challenge of long term occlusion in tracking problem is addressed by the proposed adaptive learning rate. The proposed method was tested on commonly used datasets with typical challenges in the field of object tracking. The results are presented in form of snapshots. Meanwhile, results are quantitatively compared to other state-of-the-art methods and showed that the proposed method outperforms others in several video clips.

Abstract. Blind source extraction (BSE) is a promising technique to solve signal mixture problems while only one or a few source signals are desired. In biomedical applications, one often knows certain prior information about a desired source signal in advance. In this paper, we explore specific prior information as a constrained condition so as to develop a flexible BSE algorithm. One can extract a desired source signal while its normalized kurtosis range is known in advance. Computer simulations on biomedical signals confirm the validity of the proposed algorithm.

Introduction

Separating original sources from their mixture is an active research field that has attracted great interest in the field of biomedical signal analysis and processing, geophysical data processing, data mining, speech analysis and image recognition, etc. [1] [2]. Blind source separation (BSS) is a powerful statistical technique in blind signal processing, which considers the simultaneous recovery of all independent components from their mixture using some statistical properties of original sources. In practice, extracting all source signals from a large number of observed sensor signals may output hundreds of recordings, which can take a long time. In most cases, only one or a few sources are desired [3]. For example, in electrocardiogram (ECG) or electroencephalogram (EEG), more than 20 sensor signals can be observed where only a few are interesting and the rest can be regarded as interfering noise [4]. Therefore it is necessary to develop a flexible method to extract only one or a few desired signals that contain useful information.

Extracting a desired source signal from its mixture can be considered a particular BSS problem, blind source extraction (BSE), where the interest is focused on extraction of a specific source signal mixed with other ancillary ones [5]. In general, both BSS and BSE are unsupervised neural network techniques to transform a multivariate random mixture into components that are mutually independent in complete statistical sense. Traditional BSS method aims to separate all source signals simultaneously, whereas BSE is to extract only one or a few desired sources with some statistical properties instead of all sources [6]. In contrast to BSS, BSE provides more flexibility and has some potential advantages in terms of computational complexity especially when the spatial dimension of observed mixtures is large and the number of desired signals is small [5].

In many applications especially in biomedical signal processing, one may know certain prior information about a desired source signal in advance [4]. It is desirable to incorporate such prior information into the BSS/BSE model by using minor modifications of the estimation process, essentially imposing constraints on the model, thus making the output is the desired one. To achieve this goal, we introduce specific prior information about a desired source signal to a classical cost function so as to develop a flexible BSE algorithm. One can extract a desired source signal exclusively while its normalized kurtosis range is known in advance.

The Proposed Algorithm

Suppose n uncorrelated zero-mean sources $s(t) = [s_1(t), \cdots, s_n(t)]^T$ are mixed through an $n \times n$ nonsingular mixing matrix $A = [A_1, \cdots, A_n]$ to get the mixture $x(t) = [x_1(t), \cdots, x_n(t)]^T$ as

$$x(t) = As(t), \tag{1}$$

where superscript T denotes the transpose of vectors or matrices and t is the discrete time index. The crucial assumption at the core of BSS/BSE problem is that the original source signals are mutually statistical independent. Fundamentally, BSE is to find a specific vector w and then apply a process to the observed mixture, thus making $y(t) = w^T x(t)$ is a good approximation to the desired source signal.

To formulate the BSS/BSE problem, one must develop an appropriate cost function that depends on the parameters of the neural network model in (1) [3]. To extract an independent source signal, a flexible cost function is the one on the basis of negentropy [1], defined by

$$J(y) = \rho[E\{G(y)\} - E\{G(v)\}]^2, \tag{2}$$

where $y = w^T x$ is the algorithm output, ρ is a positive constant, v is a Gaussian variable with zero mean and unit variance, $E\{\cdot\}$ denotes the statistical expectation operator, and $G(\cdot)$ can be any non-quadratic function. The following practical functions are suggested for $G(\cdot)$ [1] [3]:

$$G_1(y) = \log coash(a_1 y)/a_1, \tag{3}$$

$$G_2(y) = \exp(-\frac{1}{2}a_2 y^2)/a_2, \tag{4}$$

$$G_3(y) = y^4/4, \tag{5}$$

where $1 \le a_1 \le 2$ and $a_2 \approx 1$. G_1 is a good general purpose function; G_2 may be better when the independent components are highly super-Gaussian, or when robustness is very important; G_3 is justified on statistical grounds only for estimating sub-Gaussian signals when there are no outliers. The cost function in (2) is robust to outliers and spiky noise. Maximizing this function can derive the famous one-unit FastICA algorithm [1]. As an algorithm on the basis of negentropy, FastICA will theoretically converge to an independent component, which has the maximum negentropy of all underlying components [1] [3]. That is to say, when one wants to extract a specific source signal, the FastICA algorithm is of little use. In BSS/BSE problem, one often knows prior information about the desired signal in advance. Therefore we use specific prior information to improve the FastICA algorithm, thus ensuring the output is necessarily the desired one [4].

In this paper, we assume that we have prior information about the desired source signal y as follows:

$$kurt4(y) \in [a, b], \tag{6}$$

where $kurt4(y)$ is the normalized kurtosis value of signal y, defined by

$$kurt(y) = E\{y^4\} - 3(E\{y^2\})^2, \tag{7}$$

and a and b are given scalars with $a<b$. The assumption denotes that the normalized kurtosis value of the desired source signal lies in a specific range whereas other undesired signals do not belong to this range. That is to say, the scope in (6) is correlated with the desired source signal exclusively. Maximizing the cost function in (2) and take into account the constraint in (6), we obtain the following constrained optimization problem:

$$\begin{cases} \max \quad J(w) = \rho[E\{G(w^T x)\} - E\{G(v)\}]^2 \\ s.t. \quad a \le kurt4(y) \le b \quad and \quad w^T w = 1 \end{cases}. \tag{8}$$

The Lagrange multipliers method may avoid the ill conditioning and numerical problems for limitable values of the penalty parameter in the penalty function method [2]. Therefore we explore the Lagrange multipliers method to get the optimal solution for the problem in (8). The augmented Lagrange multipliers is defined as

$$L(w, \lambda) = J(w) + \lambda\{[\max\{0, -(kurt4(w^T x) - a)\}]^2 + [\max\{0, -(b - kurt4(w^T x))\}]^2\} \tag{9}$$

where λ is the non-negative Lagrange multiplier corresponding to the inequality constraints in (6). The maximum point of this Lagrange function, where its gradient is zero with respect to w and λ, gives the solution to the constrained optimization problem in (8). The gradient of $L(w, \lambda)$ with respect to w can be calculated as follows:

if $kurt4(y) \le a$ then

$$\frac{\partial L(w,\lambda)}{\partial w} = \frac{\partial J(w)}{\partial w} - 2\lambda[a - kurt4(w^T x)]\frac{\partial kurt4(w^T x)}{\partial w}; \tag{10}$$

if $a \le kurt4(y) \le b$ then

$$\frac{\partial L(w,\lambda)}{\partial w} = \frac{\partial J(w)}{\partial w}; \tag{11}$$

if $kurt4(y) \ge b$ then

$$\frac{\partial L(w,\lambda)}{\partial w} = \frac{\partial J(w)}{\partial w} + 2\lambda[kurt4(w^T x) - b]\frac{\partial kurt4(w^T x)}{\partial w}. \tag{12}$$

Applying the gradient maximize learning rule [1] [2] to Eq.(9), we further derive a learning algorithm:

$$w \leftarrow w + \mu\frac{\partial L(w,\lambda)}{\partial w}, \tag{13}$$

$$w \leftarrow w/\|w\|, \tag{14}$$

where μ is the learning rate that controls the size of each step and is usually fixed during the iterative process.

Computer Simulations

The ABio7 data set proposed by Allan Barros [7] is a benchmark, which contains seven typical biomedical source signals. Each signal has 5000 samples with zero means and unit variances. This data set has been used by many BSS/BSE algorithms [3] [4]. Due to space constraints, here we only adopted three source signals, denoted by s1, s2, s3 in Figure 1. Their normalized kurtosis values are 37, -0.5 and -1.05, respectively.

A 3×3 mixed matrix A was randomly generated with rows $A1$=[0.149 0.219 0.561], $A2$=[0.113 0.872 0.258] and $A3$=[0.489 0.229 0.709]. The adopted three source signals were mixed by matrix A. The mixed results are shown in Figure 2.

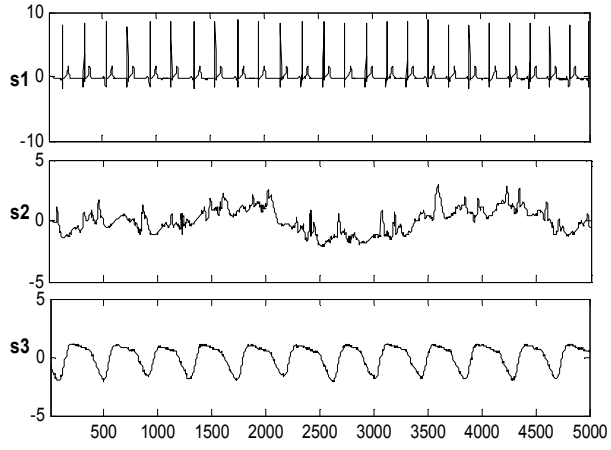

Fig.1. Original biomedical signals

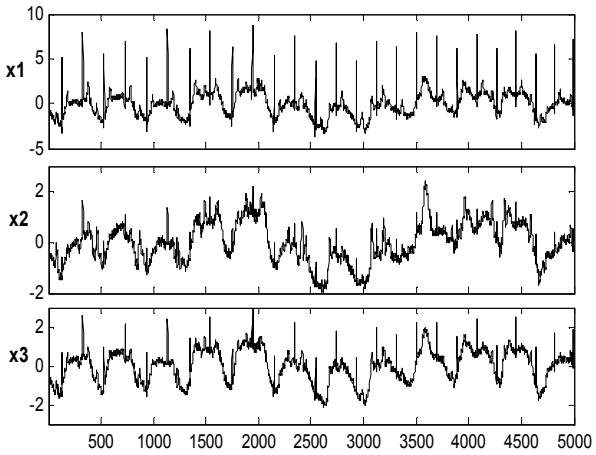

Fig.2. Signal mixture

Our objective is to extract source signals from their mixture shown in Figure 2. First, we set a=35 and b=38 to extract the ECG signal s1. With the learning rate μ, we can control the size of each step. In these simulations, μ was experientially set to 0.004; the Lagrange multiplier λ was initially set to 3 and gradually increased as the algorithm progressed by $\lambda = \lambda(1+1/k)$ where k is the iterative number. In the same way, we set a=-0.6 and b=0.2 to extract the second source signal s2, set a=-1.8 and b=-0.7 to extract the last one. Simulation results are shown in Figure 3 in turn.

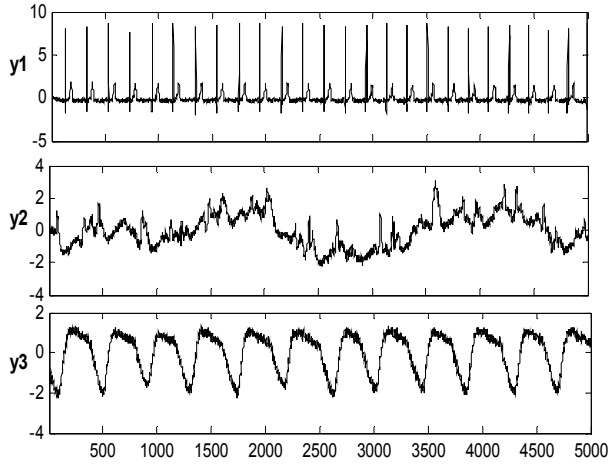

Fig.3. Signals extracted by the proposed algorithm

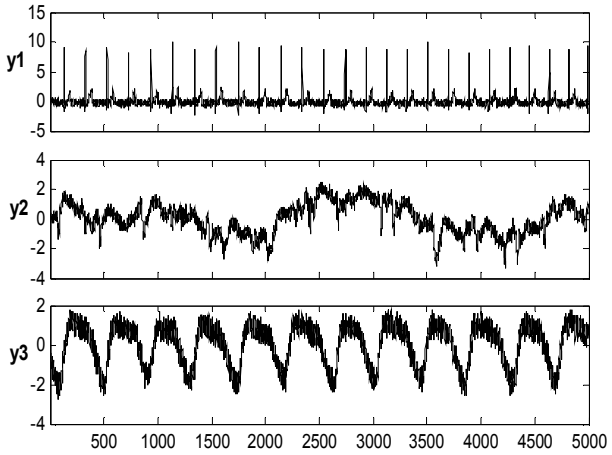

Fig.4. Signals extracted by the FastICA algorithm

Conclusion

This paper proposes a flexible BSE algorithm on the basis of normalized kurtosis. It can extract a desired signal as the first output while its normalized kurtosis value range is known in advance, regardless whether the corresponding value is the largest or not in the observed mixture. It is computationally simple, efficient, and provides more flexibility than traditional BSS algorithms. Computer simulations on biomedical data validates its good performance.

Abstract. As a famous one-unit algorithm, FastICA can extract source signals one by one. In many applications, someone is only interested in a specific source signal. Through incorporating reference about the desired signal into a negentropy based contrast function, a constrained optimization problem is formed. Then an improved method is proposed which can extract the desired source signal exclusively. Computer simulations demonstrate its good performance.

Introduction

Independent component analysis (ICA) is a statistical and computational technique for revealing hidden factors that underlie sets of random variables, measurements, or signals [1]. As an extension to principal component analysis and factor analysis, ICA has become a powerful method for signal processing in the last few years, principally due to its ability to solve the problem of blind source separation (BSS) successfully [2].

The basic ICA model can be described as follows

$$X = AS \tag{1}$$

where $S = (S_1, \cdots, S_m)^T$ denotes the original independent sources and $X = (X_1, \cdots, X_n)^T$ denotes mixtures of original sources, and A is the unknown m×n constant mixing matrix. Here the term blind refers to the fact that neither the original sources nor the system are known in advance. The only assumptions about the model are that the original sources are statistically independent and that some general model is followed by the system [3]. The objective of ICA is to estimate independent components from observed mixtures. In many applications, the number of original sources is large and only one or a few are desired. In such cases, extracting all independent signals may output hundreds of recordings, thus causing heavily computation burden. It is necessary to develop a robust method to extract a desired original source exclusively.

To formulate the ICA problem, one must form an appropriate contrast function, which is greatly dependent on the parameters of the specified neural network model in (1). Maximization/Minimization of such a contrast function should enable the output of the model to satisfy the statistical conditions of stochastic independence and other inherent properties, depending on the specific problem [4] [5]. According to the Central Limit Theorem, sums of non-Gaussian independent random variables are closer to Gaussian than the original sources [6]. Therefore, a very intuitive and important principle of component estimation is to maximize/minimize non-Gaussianity. To extract an independent source signal, a reliable contrast function is given on the basis of negentropy [1], defined by

$$J(y) = \rho[E\{G(y)\} - E\{G(v)\}]^2, \tag{2}$$

where $y = w^T x$ is the algorithm output, ρ is a positive constant, and v is a Gaussian variable with zero mean and unit variance, $E\{\cdot\}$ denotes the statistical expectation operator, and $G(\cdot)$ can be any non-quadratic function. The following practical functions are suggested for $G(\cdot)$ [1] [3]:

$$G_1(y) = \log coash(a_1 y)/a_1, \tag{3}$$

$$G_2(y) = \exp(-\frac{1}{2}a_2 y^2)/a_2, \tag{4}$$

$$G_3(y) = y^4/4, \tag{5}$$

where $1 \le a_1 \le 2$ and $a_2 \approx 1$. G_1 is a good general purpose function; G_2 may be better when the independent components are highly super-Gaussian, or when robustness is very important; G_3 is justified on statistical grounds only for estimating sub-Gaussian signals when there are no outliers.

Maximizing function (2) can derive the famous one-unit FastICA algorithm [1], which will theoretically converge to an independent component having the maximum negentropy of all underlying components. In other words, when one wants to extract a specific source signal, the FastICA algorithm is of little use. In many applications especially in biomedical signal processing, one often knows specific prior information about the desired signal in advance. In the following we use specific prior information as reference to improve the FastICA algorithm, thus ensuring the output is necessarily the desired one [4].

The Extraction Algorithm with Reference

Denote the recovered signal y and its corresponding reference signal r. The closeness measure between y and r can be described as $\varepsilon(y,r)$. It is important to select a suitable distance, depending on the specific problem, as the closeness measure. In this paper, we select $\varepsilon(y,r) = E\{(y-r)^2\}$ and $\varepsilon(y,r) = 1/(E\{yr\})^2$. Suppose that the contrast function (2) has m local or global solutions w_i $(\mathrm{i} = 1,\cdots,m)$, which can give m estimations of the m source signals. From the selected closeness measure, one can deduce that $\varepsilon(w^{*T}\tilde{x}, r)$ is the minimum of $\varepsilon(w_i^T\tilde{x}, r),\ i = 1,\cdots,m$, i.e.,

$$\varepsilon(w^{*T}\tilde{x}, r) \le \varepsilon(w_1^T\tilde{x}, r) \le \cdots \le \varepsilon(w_m^T\tilde{x}, r) \tag{6}$$

where the optimum vector w^* corresponds to the desired output. Thus an appropriate threshold can be utilized to distinguish the desired source signal y^* from other ones, which means that the extracted signal $w^{*T}\tilde{x}$ is equal to y^* if and only if the following inequality relationship is satisfied:

$$h(w) = \varepsilon(w^T\tilde{x}, r) - \xi \le 0 \tag{7}$$

where $\xi \in [\varepsilon(w^{*T}\tilde{x}, r), \varepsilon(w_1^T\tilde{x}, r))$ is a threshold parameter.

By considering $h(w)$ a constraint incorporated into the contrast function (2), we develop the following constrained optimization problem for extraction of a desired source signal:

$$\begin{cases} \max & J(y) = \rho[E\{G(y)\} - E\{G(v)\}]^2 \\ s.t. & h(w) \le 0, \|w\| = 1 \end{cases} \tag{8}$$

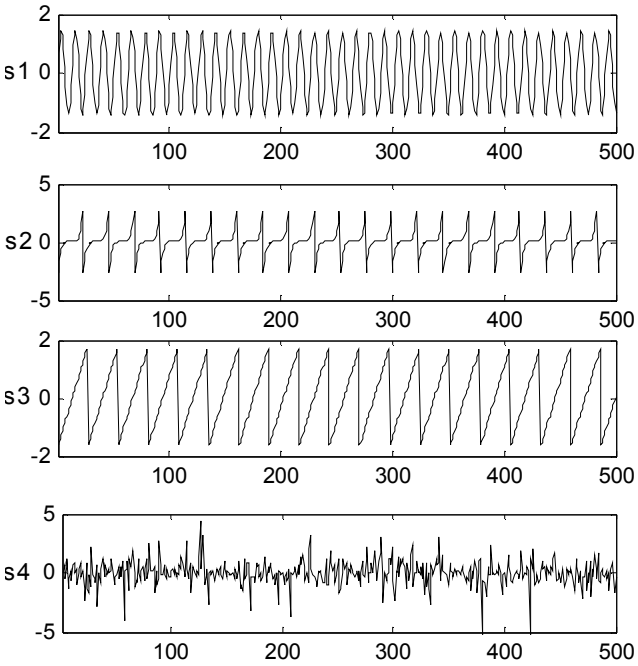
As an additional constraint, $h(w)$ is introduced to guide the signal extraction process, ensuring that the resultant solution is a global maximum. Such a constrained optimization problem efficiently considers prior information about the desired source signal. Therefore one can extract the desired original source exclusively concerned with the corresponding reference.

Through maximizing the negentropy based contrast function for FastICA defined in (2), one can expect to adjust w in the direction of any local optimum of $J(y)$ such that one can get any estimation of the original sources; through maximizing the closeness measure function defined in (5), one can expect to adjust w in the direction of the demixing vector whose corresponding output is closest to the reference signal r such that one can get the desired original source exclusively. Generally speaking, the former can be considered a coarse pre-processing while the latter is an elaborate processing, thus the desired signals can be successfully extracted through alternately performing these two processes. Moreover, the latter can greatly accelerate the

convergence speed. In contrast, the proposed method can achieve good flexibility and relatively low computation load compared with the earlier ones.

Simulation Results

We tested the proposed algorithm in this paper with a synthetic data set of four known source signals, which was also used for testing the previous ICA methods in [7] [9]. The four original sources were depicted in Figure 1. They were sinusoid, funny curve, saw-tooth and impulsive noise, respectively. These sources were linearly mixed by a randomly generated mixing matrix. The mixed signals were depicted in Figure 2. Obviously, the waveform of any source signal was invisible in the mixed signals.



Fg.1 Four synthetic original sources

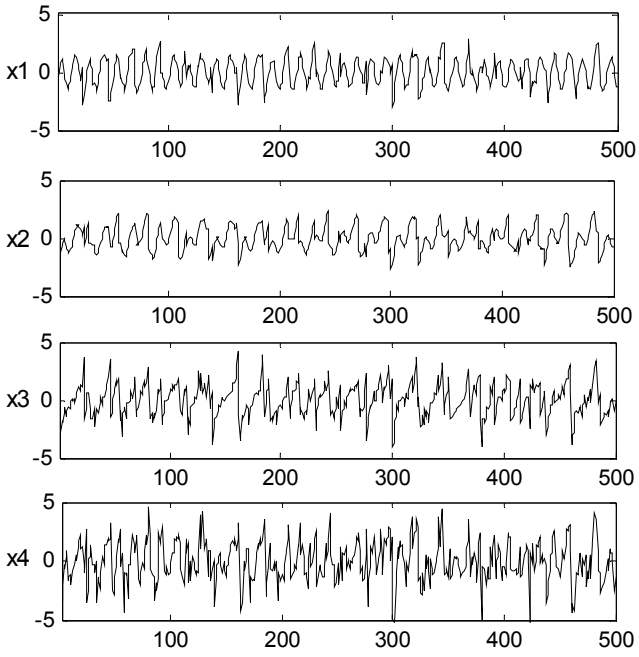


Fig.2 Signals mixed by a random matrix

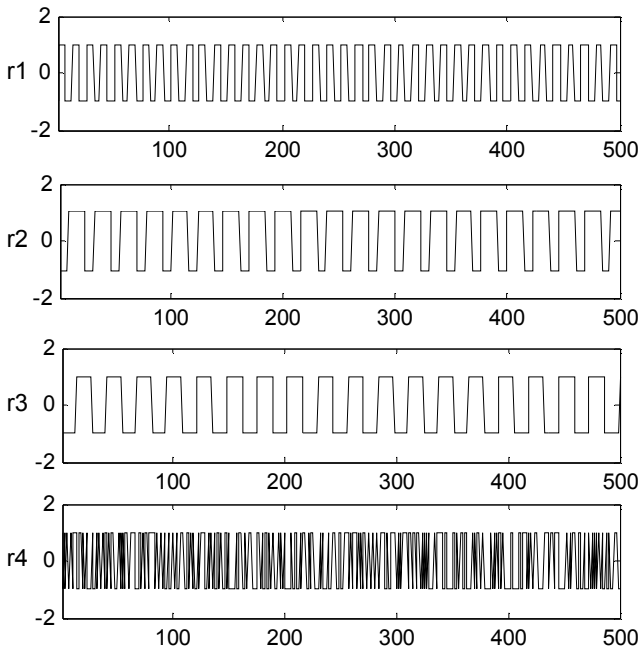

Fig.3 Four reference signals

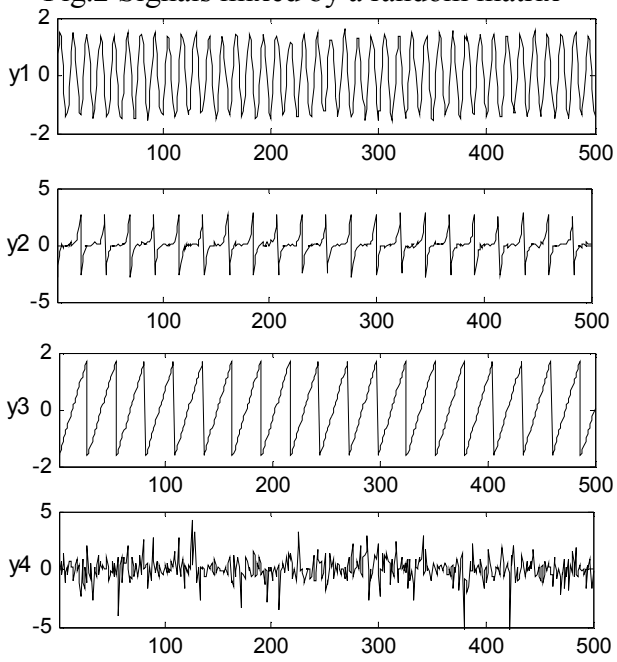

Fg.4 The extracted signals

An appropriate reference signal is important for the ICA algorithm with reference to extract a desired source signal. We intentionally formed reference signals as coarse representations of the

original sources except that the morphology of the underlying sources was precisely known. Four reference signals in Figure 3 were constructed with sign operation to roughly give the signs of the four original sources. In fact, these reference signals only carried the same frequency and phase as the corresponding original sources.

Our objective was to extract the four source signals from the signal mixtures shown in Figure 2. In these simulations, we adopted the four reference signals shown in Figure 3 in turn and performed the proposed algorithm in this paper on these signal mixtures. Typical simulation results were shown in Figure 4. The selection of the closeness measure is greatly dependent on the form of reference signal and the function G in (5). Indeed, it is important to select a suitable distance, depending on the specific problem, as the closeness measure. Here we selected $\varepsilon(y,r) = E\{(y-r)^2\}$. From these simulation results, one can find that the proposed algorithm may successfully extract the corresponding source signals although each reference signal is not a perfect match to the corresponding original source. At the same time, it can achieve good flexibility and relatively low computation load compared with the earlier methods.

Conclusion

Recently, ICA technique has received much research attention in the domain of applied mathematics, neural networks and statistical signal processing. Through incorporating specific prior information about a desired signal into the negentropy contrast function for FastICA, a constrained optimization problem is formed whose inequality constraint term is a closeness measure between the desired signal and its corresponding reference. By alternately optimizing the negentropy contrast function for FastICA and the closeness measure proposed in this paper, an improved method for signal extraction is introduced. It can achieve good flexibility and relatively low computation load compared with the earlier methods. Computer simulations demonstrate its good performance. Due to space constraints, we do not discuss the selection of threshold value in detail. How to design a suitable threshold is our future works.

Keywords: Remote Sensing Image; Classification; PCA; Spatial-Spectra Features

Abstract. According to the problem that the traditional remote sensing image classification methods focus only on analyzing the spectral features and have low utilization of the spatial information, a new spatial-spectral classification method is proposed in this paper, its core idea is to combine the spectral features base on the Principal Component Analysis (PCA) algorithm with the spatial features extracted by the Gabor filter. Experiments show that, compared with the traditional classification methods, the proposed method can improve the classification accuracy and the Kappa coefficient, which means to bring better classification and visual effects.

Introduction

Remote sensing image is widely used in a lot of fields, such as agricultural production, mineral mapping, target identification and detection, disaster warning, military reconnaissance, urban planning and so on [1]. The main feature of remote sensing image is that they have a very high spectral resolution, so they can obtain very narrow band ranges and get a large number of spectral bands, which could result in a continuous spectrum image data that containing a wealth of information [2].

In image processing, spatial information plays a critical role. Researches show that, the Gabor features have the ability to represent useful spatial information, showing good application value in the texture segmentation [3]. Literature [4] applied it into the face image representation and recognition. In literature [5], spatial feature extraction models for remote sensing image were discussed.

It needs to be emphasized that the remote sensing data should be treated as images instead of a mere collection of independent and identically distributed pixels [6]. Therefore, in order to improve the classification effects of remote sensing image, this paper proposes a remote sensing classification method by means of using the sparse representation, meanwhile, considering the spatial-spectral features in the image. Through the establishment of classification simulation model, the effectiveness of the method is analyzed and verified.

The Proposed Gabor-PCA based Spatial-Spectral Classification method

Better classification performance could not be achieved by just using spectral features while ignoring spatial features. In order to improve the classification accuracy of the image, the paper proposes the spatial-spectral method for the remote sensing image classification, while in the spectral feature extraction, the Principal Component Analysis (PCA) algorithm is used and the Gabor filter is applied in the spatial aspect. The proposed method first extracts the spatial-spectral features of the image, and then classifies the remote sensing image based on sparse representation classification (SRC) method, which improves the classification performance.

The implementation procedure of the proposed method is as follows:

First of all, extracting the image features from the original remote sensing data. Extract the spatial texture features using equation (1) [3]:

$$G(x,y,\theta,\lambda,\sigma,\gamma)=\exp(-\frac{x'^2+\gamma'^2y'^2}{2\sigma^2})\cos(2\pi\frac{x'}{\lambda}+\varphi) \tag{1}$$

where, $x'=x\cos\theta+y\sin\theta$, $y'=-x\cos\theta+y\sin\theta$, λ represents the wavelength of the cosine factor, θ represents the orientation of the normal to the parallel stripes of a Gabor function, φ is the phase offset, σ is the standard deviation of the Gaussian envelope, and γ is the spatial aspect ratio. In fact, the Gabor function is a special expression of the sinusoidal wave. However, a Gaussian function will be formed to make the Gabor filter.

Meanwhile, extract the spectral features using the PCA algorithm, which is a widely used dimensionality reduction technology in data analysis [1].Also, it computes the low-dimensional representation of a high-dimensional data set, and the algorithm can most faithfully preserve its covariance structure [7]. One needs to solve the eigenvalues and eigenvectors of the covariance matrix. The outputs of PCA are simply the coordinates of the input patterns in this subspace, and through using the directions specified by these eigenvectors to construct the principal axes. In PCA, the first few principal components contain the most information, and the remaining principal components contain much less information [8].

Then, combine the spatial and spectral features. Suppose the remote sensing image contains k different classes of samples, and the entire spatial-spectral features training set is A, $A=[A_1,\cdots,A_i,\cdots,A_k]$, where A_i is the training set of the ith $(1\le i\le k)$ class. Then, the linear representation of x can be rewritten as: $x=A\hat{s}$, where $\hat{s}$ is a coefficient vector.

In order to obtain $\hat{s}$, the following equation needs to be solved [9]:

$$\hat{s}=\min_s\frac{1}{2}\|x-As\|_2^2+\lambda\|s\|_1 \tag{2}$$

where λ is a compromise fact between data reconstruction and the sparsity, satisfying $\lambda>0$.

The redundancy reconstruct of the remote sensing image for the i th class is as follows [10]:

$$r_i(x)=\|x-A_i\hat{s}_i\|_2, i=1,2,\cdots,k \tag{3}$$

where $\hat{s}_i$ is the coefficient vector associated with the i th class.

Then the class label can be finally determined by the equation (4) [11]:

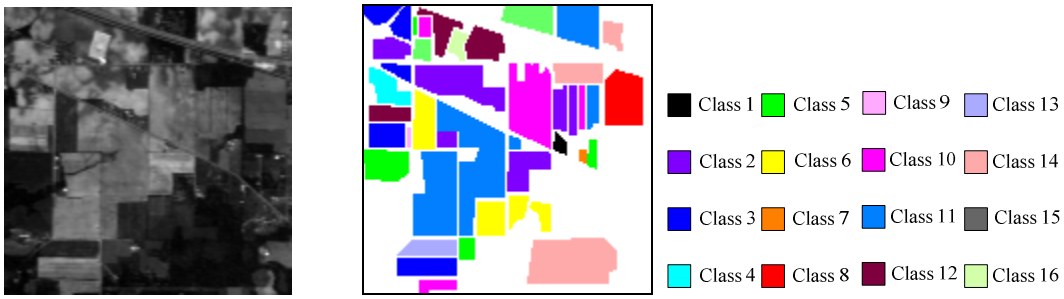
$$Class(x)=\min_{i=1,\cdots,k} r_i(x) \tag{4}$$

Experimental Results and Analysis

Hardware environment for the simulation is Intel (R) Xeon (R) CPU ES-16200, and the memory is 8 GB. Software environment for the simulation is Microsoft Windows 7, MATLAB 2010b.

Use a remote sensing image of the Indian Pine in Indiana State with a spatial resolution of 20 m for the simulation. In the original image, it has a size of 145×145 pixels. After eliminating the water absorption and low SNR bands in the original 220 bands, 200 bands are selected for simulation.

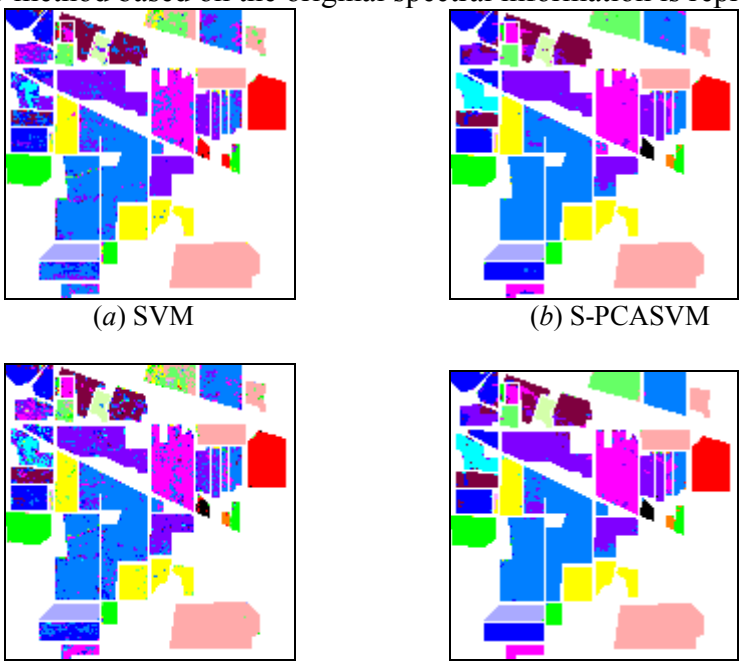
The paper selects all 16 typical land-cover classes which marked as the class 1-class 16 to do the simulation. All the above samples are used as the test set, and around 10% samples of each class are extracted uniformly as the training set. Figure 1 shows the information of the reference map.



(*a*) Original Image. (*b*) Ground truth map.

Fig.1. Remote sensing image of Indian Pine.

The paper compares and analyzes the proposed method with Support Vector Machine (SVM)[2] [12]. The classification results of different methods are shown in figure 2. Here, the classification results are evaluated by overall accuracy (OA) and Kappa coefficient. Depend on the criteria, the evaluation results are shown in table 1. SVM method based on the original spectral information is represented by SVM, SVM method based on the PCA based spatial-spectral features is represented by S-PCASVM, SRC method based on the original spectral information is represented by SRC.



(*a*) SVM (*b*) S-PCASVM

(*c*) SRC (*d*) Proposed method.

Fig.2. Classification results.

Table 1 Quantitative assessment of different methods

Criteria	SVM	S-PCASVM	SRC	Proposed method
OA (%)	81.98	94.05	84.15	95.24
Kappa (%)	79.27	93.21	81.85	94.58

It is very intuitive to see from the figure 2 and table 1 that, the classification performances based on the spatial-spectral features, which can describe the remote sensing image more comprehensively from both aspects of spatial and spectral, are better than the classification performances only based on the original spectral information. It can be seen, out of the four methods, the proposed method obtains the optimal visual effects and the best classification criteria.

Conclusion

A new spatial-spectral classification method for remote sensing image is proposed in this paper. The method first extracts the spatial-spectral features of the image separately by the Gabor filter and the PCA algorithm, then solves the sparse representation of the remote sensing image, and finally, determines the class label by calculating the corresponding redundancy of the reconstructed image

for each class. The simulation results show that, the proposed method has better classification performance than the classification methods, which only consider the spectral information, in terms of either subjective or object evaluation criteria.

Keywords: MIMO Radar; Hybrid Chaos; Orthogonal Discrete Frequency-Poly Phase Coded; Waveform Design

Abstract. Based on the good correlation and randomness of chaos, this paper uses hybrid Bernouli and Logistic chaotic maps to increase the complexity of chaos, at the same time, we do a combination of discrete frequency coded of non full code sets and poly phase coded, and then hybrid modulation waveforms base on hybrid chaos is proposed for MIMO radar. On the basis of the expression of average ambiguity function is derived, the average fuzzy characteristics of signal waveforms and orthogonality are analyzed in theory. Finally, numerical simulation results validate the correctness of the analysis and the reliability of the signal model.

Introduction

MIMO system is that a system has multiple-input and multiple-output, we apply this concept to on radar, so the MIMO radar which is a novel class of radar system and attracts extensive attention, is formed. Orthogonal radar waveform design is important to the performance of the radar, can make the whole radar system are very difficult to be cross positioned by enemy spy plane, so as to improve the battlefield survivability of the radar system. Commonly signals have orthogonal phase coded signal [1], orthogonal discrete frequency coded signal [2] and multi-carrier signals.

Poly phase coded signals and discrete coded signals are commonly used in MIMO radar waveforms. For the first time Deng [3] introduced modern computational methods to optimize waveform design, and then designed orthogonal discrete frequency coded associated with excellent characteristics by simulated annealing algorithm. Genetic Optimization algorithm is used to design phase coded signals for MIMO radar in [4]. Although the genetic algorithm can get some good waveform sets, but time-consuming, low efficiency of the algorithm.

To overcome those drawbacks, chaos has a sensitivity to initial values, and good autocorrelation and cross correlation properties [2][5]. In this paper, hybrid chaotic maps are applied on the modulated waveforms. In order to obtain both the advantages of discrete orthogonal frequency modulated and phase modulated signals, which are combined, and supplement mutual deficiencies. Compared with the single modulation signals, this paper retains Broadband spectral characteristics of phase modulated signals and anti-jamming advantage of orthogonal discrete frequency, greatly reduce the probability of being intercepted by enemy.

Hybrid Coded Model

Assuming MIMO radars have L independent transmitting unit, namely that waveform sets consist of L signals with each signal containing N sub-pulses of time duration T. The expression of MIMO radar orthogonal discrete frequency- phase hybrid coded waveform is shown as:

$$S_i^l(t) = e^{j2\pi f_i^l t} \otimes 1/\sqrt{N} \sum_{n=0}^{N-1} C_n V_1(t-nT) = 1/\sqrt{N} \sum_{n=0}^{N-1} C_n e^{j2\pi f_i^l (t-nT)} \quad ,0 < t < NT \qquad (1)$$

Where $V_1(t) = 1/\sqrt{T}$, $0<t<T$, C_n is the coefficients of coded sequences, they can be selected from $e^{j\cdot n\cdot 2\pi/M}$, $n \in \{0, 1, 2, \dots, M\text{-}1\}$. f_i^l is the frequency of sub-pulse i of signal l in the signal sets .where $\Delta f = 1/T$, frequency coded of the signal l can be expressed as $\{f_i\} = \{b_1\Delta f, b_2\Delta f, \dots, b_N\Delta f\}$. Not all will be transmitted for the frequency coded, but they don't repeat, it is a non-full code. The coefficients $\{b_1, b_2, \dots, b_N\}$ from $b_i \in \{1,2,3,\dots,P\}$, $N<P$. Namely , N non-repetitive discrete frequency coded are selected from b_i. In this paper the sub-pulse width of phase coded and discrete frequency coded are same.

The analysis of waveforms correlation properties

(1)Average Ambiguity Properties

Due to the randomness and sensitivity of chaotic map, single pulse can not accurately reflect the fuzzy characteristics of the whole. So we select the statistical average ambiguity function in time NT. where τ is delay, f_d is Doppler shift. The expression is defined as follows:

$$A(\tau, f_d) = 1/NT \int_0^{NT} S^*(t) S(t-\tau) \exp(j2\pi f_d t)\, dt \tag{2}$$

Make (1) into (2), the expression is simplified to obtain as：

$$\begin{aligned} A(\tau, f_d) &= 1/N^2T^2 \sum_{n=0}^{N-1} C_n{}^2 e^{-j2\pi b_n \frac{\tau}{T}} \int_a^b e^{j2\pi f_d t} dt + 1/N^2T^2 \sum_{n=0}^{N-1} \sum_{m=0, m\neq n}^{N-1} C_n C_m \cdot \\ &\exp\left(j2\pi \left(nb_n - mb_m - b_m \frac{\tau}{T} \right) \right) \cdot \int_c^d e^{-j2\pi b_n \frac{t}{T}} e^{j2\pi b_m \frac{t}{T}} e^{j2\pi f_d t} dt \end{aligned} \tag{3}$$

For (a, b),(c, d): when $0<\tau<T$, $n=m+1$,$a=n\,T+\tau$, $b=(n+1)T$, $c=n\,T$, $d=n\,T+\tau$, take these into (3) can be shown：

$$\begin{aligned} A(\tau, f_d) &= \frac{1}{N^2T^2} \sum_{n=0}^{N-1} C_n{}^2 e^{-j2\pi b_n \frac{\tau}{T}} e^{j2\pi fd(nT+\tau)} \frac{e^{j2\pi fd(T-\tau)} - 1}{j2\pi f_d} + 1/N^2T^2 \sum_{n=0}^{N-1} \sum_{m=0, m\neq n}^{N-1} C_n C_{n-1} \\ &\cdot e^{j2\pi\left(nTfd + b_{n-1} - b_{n-1}\frac{\tau}{T} \right)} \cdot \left(\exp j2\pi \left(fd + \frac{b_{n-1}}{T} - \frac{b_n}{T} \right) \tau - 1 \right) \Big/ j2\pi \left(fd + \frac{b_{n-1}}{T} - \frac{b_n}{T} \right) \end{aligned} \tag{4}$$

When $\tau>T$, in order to facilitate the calculation of expression, set $q\,T< \tau < (q+1)\,T$, $q=1,2\dots N\text{-}2$, now $c=n\,T$, $d=(n\text{-}q)T+\tau$, $n=1+m+q$, we get：

$$\begin{aligned} A(\tau, f_d) &= \frac{1}{N^2T^2} \sum_{n=0}^{N-1} C_n C_{n-q-1} \exp\left(j2\pi \left(\left(q+1-\frac{\tau}{T} \right) b_{n-q-1} + nTf_d \right) \right) \\ &\left(\exp\left(j2\pi \left(f_d + \frac{b_{n-q-1}}{T} - \frac{b_n}{T} \right) (\tau - qT) \right) - 1 \right) \Big/ \left(j2\pi \left(f_d + \frac{b_{n-q-1}}{T} - \frac{b_n}{T} \right) \right) \end{aligned} \tag{5}$$

Ambiguity function is symmetric, $|A(\tau, f_d)| = |A(-\tau, -f_d)|$. Thus the complete expression of the statistical average ambiguity function $A(\tau, f_d)$ can be obtained.

(2) Orthogonal Characteristic

For the aperiodic signals, Orthogonal signals required cross-correlation side lobe peak (CP) as small as possible, while autocorrelation side lobe peak (ASP) as low as possible, namely, the following condition is need as:

$$AA(S_l, \tau) = 1/(NT) \int_0^{NT} S_l(t) S_l^*(t+\tau)\, dt = 1\ , \quad l = 1, 2, \cdots, L \tag{6}$$

$$CC(S_p, S_q, \tau) = 1/(NT) \int_0^{NT} S_p(t) S_q^*(t+\tau)\, dt \approx 0 \quad , \ p \neq q,\ \ p, q = 1, 2, \cdots, L \tag{7}$$

Design Method of Hybrid Waveforms

Modified form of the expression of Bernoulli chaotic function is obtained as follows: $x_{n+1}=r(x_n + w\,g\,n\,(1, 1, h))$ (mod 1) (Where $x_n \in [0, 1]$). In the type: r is an integer ($r\geq 2$), $w\,g\,n\,(1, 1, h)$ is Gaussian white noise, h is noise intensity. Modified form of Bernoulli map within a certain range is unpredictable, so that the system can be regarded as a true random bit source. Logistic function is defined as: $x_{n+1}=\beta x_n(1+x_n)$, $\beta \in [0, 4]$, $x_n \in [0, 1]$.

Design method steps are gotten as follows:

(a) Randomly selected L initial values in [0, 1]. firstly, the length of the sequences which both Logistic and Bernoulli maps with L different initial values generate , is $N/2$, and then the sequences with L different initial values do hybrid cross processed, thus consist of L hybrid chaotic sequences of length N; And then chaotic sequences obtained do uniform and four phase quantization. (b) Where select the same initial values and the same method as phase coded, but the length of the sequences which both Logistic and Bernoulli maps with L different initial values generate , is $P\times k/2$, so consist of the length of $P\times k$. Finally, chaotic sequences obtained with L different initial values are conducted by sampling interval k. Due to the sequences of hybrid chaos generated are between [0, 1] decimals, before they would be encoded as orthogonal discrete frequency, they must be an integer. Use sort function "sort" to sort the hybrid chaotic sequences, the P index values for non-full code orthogonal frequency will be returned as frequency coded, but they are selected N index values which contains all the frequency values. (c) Combination with (a) and (b)

Simulation and results

Assuming L=4, N=1024, M=4, P=1100, sub-pulse time duration is T=4us, the sampling interval is set to k=10. The parameters of Bernouli chaotic map are h=20dBw and r=2. The parameter of Logistic chaotic map is β=2. The initial values are selected from [0.1, 0.2, 0.3, 0.4]. From Fig.1, only a single peak which is concentrated in the vicinity of the center position (0, 0) can be shown, the average ambiguity function is very close to the ideal "thumbtack" in Fig.1. As can be seen from Fig.2 and 3，the waveform of autocorrelation function is similar to an impulse function, the waveform of cross-correlation is close to zero, indicating the hybrid signal waveforms have good orthogonality. When the number of the waveforms and coded length are same, in this paper average ASP and CP are respectively -32.1334dB and -33.1155dB. Compared with literature [5], it present about 10dB improvement in ASP and 13dB improvement in CP.

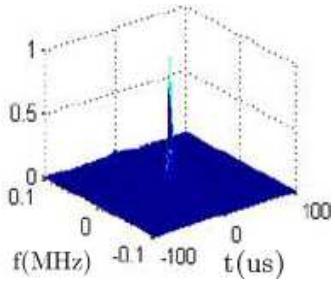

Fig.1 3D Average ambiguity

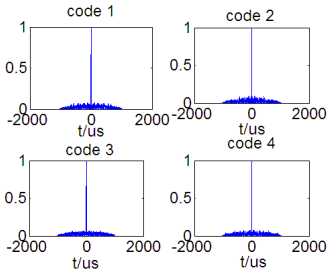

Fig.2 Autocorrelation

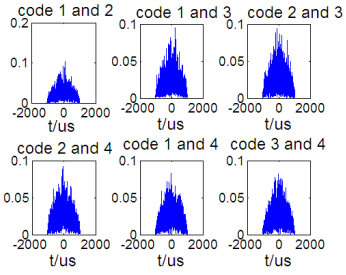

Fig.3 Cross-correlation

Conclusions

Hybrid coded waveforms based on hybrid chaos is proposed for MIMO radar application in this paper. The simulation results show that much better pulse compression performance, average ambiguity properties and less mutual interference were obtained by using good statistical properties of the hybrid chaos, compared with literature [5], ASP and CP are also greatly improved. At the same time, the optimization design of the waveforms remain to be further considered.

Keywords: Communication; Path Loss; Simulation; Model; Shipboard Radio

Abstract. According to the communication demand between warship and ChongFeng Boat or between ChongFeng Boats, this paper researched the communication capability of shipboard radio boat when sailing and islanding. It analyzed the propagation characteristics of radio, the relation between path loss and distance/path loss and frequency, discussed the influence of path loss on the capability of radio based on simulation and made a conclusion.

Introduction

Sea Battlefield is an important part of modern information war, reliable communication in sea battlefield is important foundation to win the war. Select right communication frequency is very important in complicated war electromagnetism. As the particularity of sea surface, the radio propagation on sea is different from on land, so as the influence on communication capability. According to the communication demand between warship and ChongFeng Boat or between ChongFeng Boats, when sailing and islanding, this article analyzes the propagation path loss and the communication capability about the wireless radio propagating on sea, offers the general theory of communication capability.

System Model

A. Path Loss

When communication on sea, with the changing distance and frequency, path loss maybe tens or hundreds of dB. Based on "two-path model"[1][5], this paper applied Ludiw[2] formula to calculate pass loss on sea and rivised it according to the characteristics of the distance among warships or warships and Chongfeng Boat is short, the height of antenna is low.

Smooth earth plane radio propagation formula:

$$P_r = P_t\left(\frac{\lambda}{4\pi d}\right)^2 G_T G_R \bullet \left[1 + \mathrm{Re}^{j\Delta a} + (1-R)Ae^{j\Delta a} + \ldots\right] \quad (1)$$

According to "two-path model", Received power can be deduced and simplied as follows:

$$P_r = P_t G_T G_R \frac{h_t^{\,2} h_r^{\,2}}{d^4} \quad (2)$$

Convert to be propagation loss as follows:

$$L_{bg} = 120 + 40\log d\text{-}20\log h_r h_t \qquad (dB) \quad (3)$$

The problem analyzed above is simple, however, the influence of terrain environment along the radio propagation passway should be considered in practical application.

According to Grosskopf[2] empirical formula, Median field:

$$E = \frac{12 h_t' h_r'}{d^2}\sqrt{P_t} \quad (4)$$

Thus ,the receiving power is as follows:

$$P_r = 2.5\left(\frac{h_t' h_r'}{d^2}\right)^2\left(\frac{40}{f}\right)^2 P_t \quad (5)$$

The propagation loss is as follows:

$$L_m = 40\lg d + 20\lg f - 20\lg h_t' h_r' - 36 \qquad (dB) \tag{6}$$

The above deduction considers the antenna as half wave length, whenλ/4wave length is adopted, the gain reduces 3dB, altogether, the propagation loss raises 6dB.

Radio antenna on sea is close to ground, for convenience, the influence of ground is calculated to the height of antenna, the revised height of antenna is as follows:

$$|h'| = \left| h - j\frac{\lambda\sqrt{\varepsilon}}{2\pi} \right| \tag{7}$$

On the sea, the actual measured values of VHF and UHF radio waves are close to theoretically assessed one that propagate on the smooth earth plane or spherical surface. The rapid decline caused by ships navigation is ±3dB, the slow one is about1dB. Thus, the predictive value of median path loss can be tackled as propagation along smooth ground or spherical ground.

B. Simulation model

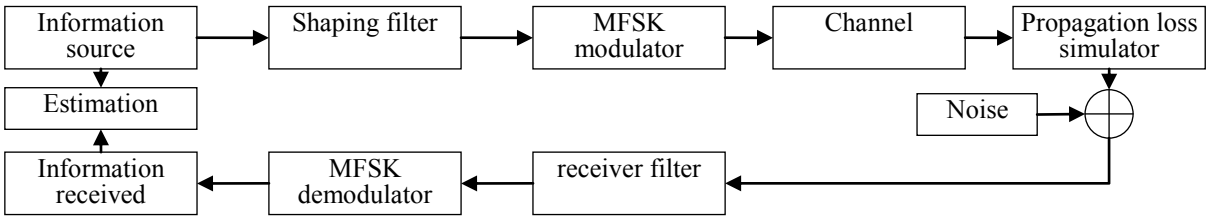

Fig.1 Base-band simulation of the influence of propagation loss to radio communication

Base-band digital transmission model is adopted in simulation, source information gets through shaping filter, modified by base-band and goes to information channel, add both practical communication path loss on sea, which simulated by propagation loss simulator, and background noise. The receiving terminal receives filter and demodulates signal. The estimation of the influence of propagation loss caused by distance and frequency to systematic bit error rate (BER). The physical model shows in Fig.1.

- **Channel parameter**. In simulation, Nonselective Rice Fading Channel [3] is adopted, when the fading factor k=0.08, the longest multipath delay Tm=10^{-6}, the greatest Doppler frequency-shift Fd=20Hz.
- **Propagation loss**. In simulation, the propagation loss depends on formula (6), the frequency range is 40-1500MHz, and the communication distance is within 5 kilometers.
- **Data rate**. For calculation convenient, data rate Rb=16K bit/s.
- **Modulate parameter**. The BFSK BER in noncoherent demodulation is $P_b = \frac{1}{2}e^{-\frac{E_s}{2N_0}}$ [3], Es is the energy of unit code element, Es=Ps/Rb, Ps is the input signal power of receiver, N_0 is the density of noise power spectrum, N_0=Pn/ B, Pn is noise power of receiver.
- **Background noise parameter**[4]. According to NBS, the background noise power P_n can be calculated by coefficient factor F_a. Pn = Fa +B-204 (dB), B is band width of receiver, B=16KHz.

Performance Analysis and Discussion

A. Propagation loss

According to the communication characteristics between warship and ChongFeng Boat or between ChongFeng Boats, this paper concentrates on the communication among radios. The radios of transmitting terminals and receiving terminals are the same type. The height of antenna in the ChongFeng Boats is about to people's eyes, which is 1.5m, the one in the warship is about 7m; the communication distance is short, usually no more than 5 kilometers; the range of frequency is 40-1500MHz; the dielectric constant of sea water is ε=80; the influence of weather, islands and other obstacles are not considered.

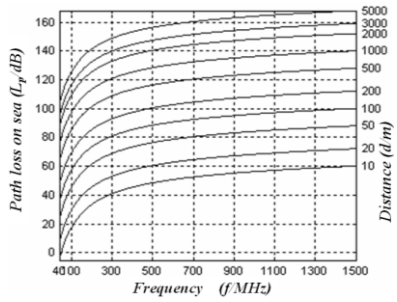

Fig.2 Path loss between ChongFeng Boats

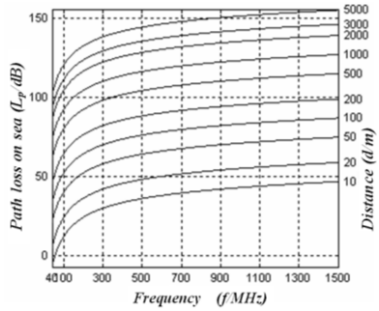

Fig.3 Path loss between warship and ChongFeng Boat

When the height of transmitting and receiving antenna are all 1.5m, the relation of path loss to frequency and distance can be obtained by simulation as in Fig.2 shows.

As the figures shows, when the communications distance increase, the propagation loss of wave grows gradually. When the communication distance is 1 kilometer, the frequency is above 100MHz, the path loss is more than 100dB, as the distance continues to increase, the increase range is getting small; in VHF frequency range, when the path loss is small, the changing range is big, in UHF frequency range, the path loss is big, however, the changing range is small.

When the height of transmitting and receiving are 1.5m and 1.7m , separately, the curves of path loss is showed in Fig.3. Compared with the above figure, the propagation loss is about 10dB decrease. The height of antenna is profoundly influence path loss, when the height of antenna increases, the communication distance is far more long, the higher frequency range can be selected.

In radio communication, the increase of distance and frequency will result in the increasing of propagation loss, which will decrease the receiving power in the receiving terminal, the input noise signal ratio of receiving terminal decreases, directly lead to the increase of systematic BER. When the loss reaches to some extent, it will influence the quality of communication heavily, even interrupt the communication. According to the derivation result of radio communication propagation loss prediction, we built a simulation model to analyze the influence of propagation loss to radio communication systematic BER. To be general, other anti-interference techniques adopted in radio communication system are not considered.

B. Coummunication capacity analysis

The definition of signal noise ratio (SNR): the ratio of input power that transmitting power reaches receiver after path loss to the input power of environment noise. By simulation, the four conditions are showed in Fig.4 as follows:

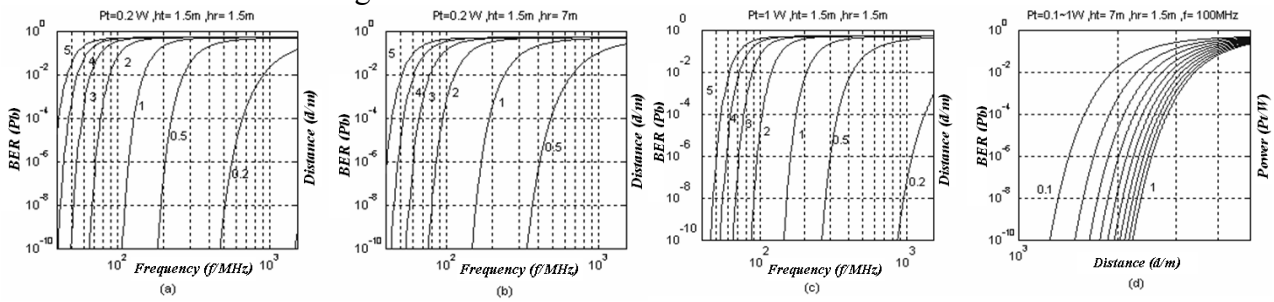

Fig.4 Simulation results

In Fig.4, when the transmitter power is 0.2W, the height of antenna is 1.5m, to ensure10^{-5} BER; the VHF band can provide long communication distance. Compared Fig.4 (a) to（c）,when the transmitter power increases five times to 1W, in the same frequency and communication distance, the signal noise rate improves about 45dB, the higher of the frequency, the lower the signal noise rate improves. In Fig.4 (b), considering that when the communication is between warship and ChongFeng Boat, the height of antennas are 7 meter and 1.5 meter separately, in the same frequency and BER, the communication distance increase 0.5 kilometer; in Fig.4 (d), the increase of transmitter power does not improve the communication distance much, 1 kilometer communication distance increase needs 6 times transmitter power increase.

Conclusion

By analysis above, when communication distance is long, VHF frequency band ranges between 20MHz-100MHz is good. If soldiers in a section below camp are close to each other, that is within 1 kilometer, the high frequency band of VHF and low frequency band of UHF could be considered. As the increase of frequency band, the environmental noise coefficient decreases, however, the path loss increases and the communication distance cuts. When the communication capacity is satisfied, the transmitter power of radio below 1W is suitable considering the portability and low energy consumption of the radio on the ChongFeng Boat.

In the practical sea environment, conditions are more complicated, especially when the weather is terrible, environmental noise, clouds and mist will influence the capacity of radio a lot. Higher demand is requested for the communication of hand-hold radio when the radios of adjacent troops and the interference of enemies add.

Study of Synchronization Strategy Based on Timestamp

Li XU

Computer College, Beijing Information Science and Technology University, Beijing 100101, China

email:xuli_lh@139.com

Keywords: Virtual Reality; 3D Rendering; Synchronization Strategy; Multichannel System

Abstract. Aiming at the characteristics of the traditional multichannel rendering synchronization strategy and the existing problems, the paper proposes a new multichannel rendering synchronization strategy based on timestamp and makes a horizontal comparison between the experimental results and the traditional strategies, as well as verifies the advantages on systematic stability and fault tolerance of network transmission. The strategy will be suitable for using in a clustered, massive and high reliable multichannel system.

Introduction

In the field of modern virtual reality, the large-scale 3D scene rendering and immersive virtual reality experience are inseparable from the multichannel display auxiliary. Using multichannel display technology can break resolution limit of single display terminal, and realize the scene representation of interaction with ultrahigh resolution.One of the crucial problems in multichannel display system is synchronization problems,it is highly important to make sure the different channels displaying the scene simultaneously and promote the performance of the scene to display.

In this paper, a multichannel synchronization technology for rendering 3D scenes are targeted research, proposes a new synchronization strategy based on timestamp, and compares with the traditional synchronization strategy. The new synchronization strategy has great advantages in flexibility and system reliability, and it has the practical value in engineering practice, and has been applied in the digital city related to some projects.

Traditional Synchronization Strategy

The basic principle of the multichannel scene rendering, one is to ensure that the dynamic display of the content of each channel to keep smooth, namely not less than 30fps frame rate, the second is to ensure that the content of the same frame in the display of the time difference value between the two channels is not higher than a specified error value, its mathematical expression is:

$$F_n - F_{n-1} \leq \frac{1}{30} \tag{1}$$

$$F_n - G_n \leq \varepsilon \tag{2}$$

F_n is execution scene rendering time channel in A, G_n is the execution scene rendering time channel in B. ε is maximum time difference between two channel in synchronous.

The Synchronization strategies of multichannel 3D scene rendering has had some research, including Genlock, the frame sync (*FrameSync*) and the swap buffer sync (*SwapBufferSync*).

Genlock is the most traditional, but also the most restrictive multichannel synchronous strategy, this method is the most accurate synchronization, but not be implemented in software, need to buy expensive professional equipment.

FrameSync strategy is a common multichannel synchronous method. It requires that each node send to the serve a ready signal when each frame of each node began real-time rendering, after the server receive ready signals of all nodes, allowing all nodes at the same time start the current frame rendering. This strategy is easy to understand, and easy to be realized from the software, but because the different node rendering pressure is different, each frame completion time is uncertain, this may cause deviation of final display results.

SwapBufferSync is an upgraded version of *FramSync*. It has been by far the most widely used. The advantage of this approach for similar types of computer equipment, the buffer swapping almost at the same time as always, thus ensures the integrality of the picture. However, the biggest problem of *SwapBufferSync* is that if a node in multichannel system occur problems (e.g. software or hardware failure) or a frame rendering pressure is very great, will cause synchronization signal to cannot be issued, then the whole system will therefore have a serious hysteresis, even deadlock may occur.

Synchronization Strategy Based on Timestamp

The comprehensive analysis on characteristics of the above sync strategy and the existing problems, we propose a new synchronization strategy based on timestamp. This strategy does not cause the entire system of hysteresis or deadlock because of the abnormal situation, therefore effectively enhance the multichannel system stability and practical value.

In our strategy, after the user interaction events are transmitted to the sync server, calculate the current position and posture of the observer on the scene, encapsulate the position and posture information of each frame to a timestamp, and transmits the frame ID of the current rendering and the position and posture (it can be expressed in a 4x4 matrix) to each child node. Synchronous server can not consider the transmission time, as long as the guarantee in accordance with sufficiently high frequency (e.g. 60Hz) issue the latest timestamp objects.

The implementation process is each client node use an independent thread to keep on reading and recording the timestamp object come from the server, and save it to a list. Independent and continuous thread is used, so this process and the nodes of the current render states were not related. In the network delay is small, it can be considered that an timestamp object on the server-side can always arrive on each node computer at the first time. When the client node began to render a new frame, it will check the timestamp list to find the Nth timestamp object which distance the end of list, access to its contents as the scene's current position and posture.

Where N is a parameter variable, it determines the ability in synchronization adaptive, because the end of the list save the latest data come from the server , in the timestamp list of the different nodes, the Nth timestamp object from the end of list can be considered to be the same.If the N value is greater, then it means the node rendering content than the server actual state with a certain delay. this delay is holistic, not a certain node behavior. Therefore the reasonable N value is set, the actual observation on the scene and interaction not to produce too much influence. Mathematical description of this process is as follows:

$$N = \frac{F_L - F_{avg}}{\Delta t} \tag{3}$$

Where F_L is the server-side latest moment, F_{avg} is multichannel optimum synchronization time, Δt is the timestamp sending interval.

The biggest characteristic of synchronization strategy based on timestamp is for abnormal node processing, when abnormal nodes appear , the strategy can ensure that the whole system is not affected at the same time, to adaptively adjust abnormal node status, and allows it to keep as much as possible with other nodes synchronization.If the server sends a timestamp object frequency is S, the client node rendering a frame time is T, the timestamp of object is F_0, then when the frame is completed, it will select the next timestamp is F_1.

$$F_1 = F_0 + T * S \tag{4}$$

We assume the server sending frequency is 60Hz, there are three rendering node in the system, they render one frame time respectively for 1/20s,1/10s and 1/5s, then according to the above formula, in every moment, each node rendering timestamp of object are shown in table 1.

Table.1. Timestamp lists of each node

moment(S)	node1	node2	node3
0.0	F0 = 1	F0 = 1	F0 = 1
0.05	F1 = 4	-	-
0.1	F2 = 7	F1 = 7	-
0.15	F3= 10	-	-
0.2	F4 = 13	F2 = 13	F1 = 13

All nodes can be seen from table 1, the rendering frame rate have significant difference, but rendering object's timestamp is always aligned. If a client node lose response, then just itself no longer receive timestamp signals from the server, will not affect the operation of the whole system.

Test Run Results

We use 3D rendering engine *OpenSceneGraph* as development environment, and use the synchronous strategy based on timestamp achieved interactive real-time rendering on any channel. A six channels LCD TV wall display effect as shown in figure 1, the load of the digital city scene for more than 20GB.

Fig.1. Multichannel LCD TV wall

Transverse comparison *SwapBufferSync* ,*FrameSync*, and the synchronization strategy based on timestamp, the results are shown in table 2

.

Table2. Three types of synchronization strategies comparison

Event	FrameSync	SwapBufferSync	BasedOnTimestamp
sync accuracy	middle	high	middle
communication mode	reply	transfer: notice; sync: reply	notice
poor network	easy to deadlock	easy to deadlock	not deadlock
client lost	temporarily delay	temporarily delay	not affected.
client delay	temporarily delay	temporarily delay	rest is normal
client failure	temporarily delay	temporarily delay	rest is normal
long running	low reliability	low reliability	high reliability

Communication mode, "reply" show client need feedback information to the server, if the network or the client failure,client may not reply ; "Notice" show client does not need feedback, so the client's fault will not affect the system itself. From the comparison results can be seen, the Synchronization strategy based on timestamp, although a little less in accuracy compare with *SwapBufferSync*, the high stability of the system , a high degree of fault-tolerant in network transmission, a single client node missing or faulty for the entire system is not affected, so it is suitable used in a clustered, massive and high reliable multichannel system.

Conclusion

The new strategy has some advantages compared with existing solutions, such as high reliability, good fault tolerance, high performance, wide usage and easy implementation. Client node failure does not cause "short-board effect" of the entire system hysteresis, meanwhile the client node has

the adaptive ability, to ignore the rendering stress problem, always in sync with the overall progress. This strategy can be used not only in real-time rendering of 3D large-scene, but also for high definition video playback, or immersion system composed of multiple special-shaped display terminal.

Keywords: WSN, data aggregation, correlation, cluster analysis

Abstract. Multi-sensor is deployed for the target-monitoring in complex environment. However, the distribution of sensory data is irregular and inconsistent and the data is also highly redundant. For the purpose of obtaining accurate information, this article proposes a method for data aggregation of multi-sensor based on clustering analysis and correlation. By computing the correlation of the sensory data and the clustering analysis, the overall distribution of the data is analyzed. Finally, the method integrates sensory data by the correlation and uses the joint probability density function to compute the best integrated point. Simulated results show that the method is more effective in data aggregation than traditional methods.

Introduction

Wireless sensor networks [1][2] are applied to many aspects in our society in resent years and obtain well economical and social effects. However, the sensory data of targets collected from the multi-sensor is of large quantity and redundant, it is necessary to deal with the problems mentioned above during the data analysis and process so that the value of the target is closer to the value of target in the actual monitoring environment. The redundant information of sensory data is reduced by the correlation and we use data aggregation technology to fuse the sensory data. So it is fairly important to improve the networks' accuracy and robustness and prolong the lifetime of the entire network system.

In the wireless sensor networks, it is necessary to distribute a large number of homogeneous sensor nodes to monitor the targets. So it's obvious that the value of sensory data is in a large scale and its distribution is redundant. Additionally, some data is singular point. It is not an effective way to fuse the data by the simple weighted average method. Unlike the static environment, the sensor nodes are always disseminated in the areas that are usually inaccessible and large scale and changing regions. More importantly, the data of monitored target is also in the varying status. So the fusing methods such as principal component analysis and variance analysis can not acquire very good results. According to the current measurement theory, the purpose of multi-sensor data aggregation [3][4][5] is that when the data is superimposed, the noise in data will disappear and the fused data will be closely related with the actual value of the targets. However, many documents just assign the weight to the different properties, which causes that the noise will not disappear completely and it will have an influence on the final fusion results.

Based on analyzing the related research about the data fusion at home and abroad in recent years, this article will propose a data fusion method based on the non-weight assignment.

Related Works

In the related documents, there are many methods that are used to describe the difference of sensory data and the data differences are generally divided into the absolute difference and the relative difference. In other words, the relationship between data is judged by the linear and nonlinear function. If the two data sets are the same, the result of data comparison is 1, or the result is 0. The key problem in this method is that the normal difference of data sets. Under the condition

that the difference of sensory data sets is very small, the two data sets are also the same and the result of comparison is also 1. If the difference is large, that is, the similarity of the two data sets is low and the two data sets are different, so the result of data comparison is 0. Therefore, the similarity of data sets can not be described simply as the linear relationship. With the difference increases, the similarity will decrease slowly. When the difference reaches a threshold, the similarity will go down quickly until it drops to 0.In some documents the truncation method [6] is adopted to deal with the problems mentioned above. Here a threshold is set to verify the data sets whether they are same or different. If the difference is beyond the threshold, the result is 0, or the result is 1. The problems with this method are that the threshold is set randomly and empirically. So it can not reflect the overall distribution of sensory data. The *arccot* function [7] is used to measure the consistency of data and shows good continuity, but the simulated figure by the function can not effectively describe the actual physical meanings of sensory data.

All the articles introduce the weight [8] concept to deal with the redundant information of data, that is, the data has different meanings. The more important the meaning is, the bigger the value of weight is. However, this method does not take the many sets of data in consideration. In other words, the correlation of data in a set is high, but the correlation is low between the sets. The data under this condition can not be fused simply by setting the different weights for different sets. Of course, in the real environment, some reasons such as the irrational sensor nodes location and environmental mutations may cause serious data inconsistency. Analysis on the data inconsistency is very important for the system faults detection. The model of multi-sensor data aggregation based on correlation and the clustering analysis computes the correlation of data sets first and then uses the clustering algorithms to display the overall distribution of data sets and proves the feasibility and efficiency of data aggregation. Finally, the model fuses the sensory data.

Correlation Computing

Definition 1: The relative data distance is defined below referring to the article [6].

$$dist_{i,j}(k)=\begin{cases}\dfrac{Min\{x_i(k),x_j(k)\}}{Max\{x_i(k),x_j(k)\}}\end{cases} \tag{1}$$

Among the formula 3.1, $dist_{i,j}(k)$ represents the distance between node i and node j at the moment k. The domain of $dist_{i,j}(k)$ is $(0,1]$.

Supposed that the data collected from the sensor nodes are all computable, the improved distance definition take the distance d_a, d_b between target and sensor nodes and the distance d_{ab} between nodes into consideration. It is obvious that the correlation is inversely related with the d_{ab} and the d_a / d_b.The schematic diagram is shown in figure 1.

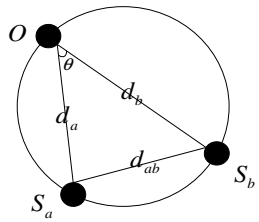

Fig. 1 Multi-sensor

Therefore, the data distance is defined as follows.

$$Sim=\begin{cases}1-dist\times\dfrac{d_a}{d_b}\dfrac{\varepsilon}{d_{ab}} & d_a\geq d_b, d_{ab}\leq d_0\\ 1-dist\times\dfrac{d_b}{d_a}\dfrac{\varepsilon}{d_{ab}} & d_a< d_b, d_{ab}> d_0\\ 0 & d_{ab}\to\infty\end{cases} \tag{2}$$

Definition 2: Data correlation is defined to measure the similarity of different sensory data sets. It is obvious that the correlation is proportionally related with the similarity, that is, if the similarity is high, the correlation is also high, or the two data sets are not related and the correlation is low and they can not be fused straightly and simply. The detailed idea is below, $LinD(X,Y)$ symbolizes the correlation. X,Y are the location of the sensor nodes. The correlation $LinD(X,Y)$ is right under the following conditions.

(1) Monotony. The overall tendency of the $LinD(X,Y)$ is falling.

(2) Exchangeability. $LinD(X,Y)=LinD(Y,X)$.

(3) The domain of the $LinD(X,Y)$ is $[0,1]$.

The closer the distance between sensor nodes, the bigger the value of the $LinD(X,Y)$ is. According to the limit concept, the value of $LinD(X,Y)$ is 0 when the distance is infinite and the value is 1 when the distance is infinitely small. The function curve is shown in figure 2.

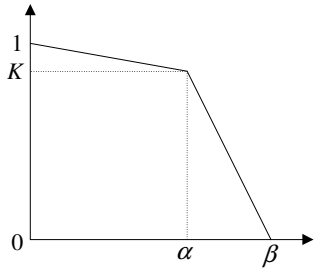

Fig.2 Data Correlation Function

As is shown is figure 2, the function curve is divided into three status. α and β are the critical points. When the data distance is smaller than the α, the correlation drops slowly. When the data distance reaches the α point, the correlation drops quickly before reaching the β point. When the data distance is beyond the β point, the value of correlation is zero. The correlation function formula is in the following section.

$$LinD=\begin{cases}1-\dfrac{1-K}{\alpha}\times Sim & Sim\le\alpha\\ \dfrac{K\times(\beta-Sim)}{\beta-\alpha} & \alpha\le Sim\le\beta\\ 0 & Sim\ge\beta\end{cases} \tag{3}$$

Among the formula 3.3, $LinD$ is the correlation function identifier. Sim is the data distance identifier. α and β are separately the critical points for correlation. K is the value of critical threshold for effective data aggregation in the function.

Clustering Analysis

Correlation computing is applied for the next clustering analysis. The clustering analysis [9][10][11] is used to cluster the data sets in order to get some sets in which contain data with close correlation. Therefore, the data in different sets has some common attributes so as to get the discrete degree of data. After computing the correlation, then clustering algorithms are applied to analyze the sensory data. Obviously, the correlation of data is stored in a matrix. $LinD_{i,j}$ represents the correlation of node i and node j. So the correlation of each sensor node $TLinD$ is computed as follows.

$$TLinD_i=\sum_{j=1}^{n}LinD_{i,j} \tag{4}$$

The bigger is the $TLinD$, the larger is the number of the nodes in the area. The smaller is the $TLinD$, the less is the number of the nodes or there are some isolated sensor nodes.

The detail procedure of the clustering analysis is in this section. Supposed that there are n sets $G_1, G_2, ..., G_n$ and they all empty at the beginning. Then the algorithm sorts the $TLinD$ by the sequence from big to small and forms the set $Degree$ .The tag of sets is $flag$.

(1) Set the $flag$ =1;

(2) Take out of first element from the set $Degree$ and put it in the set G_{flag}. Pop the data from set $Degree$ Continually and judge whether the element is beyond the threshold λ or not ant then determine whether put it in the set G_{flag} or not.

(3) Delete the elements that have been put in the set G_{flag}, and judge whether the set $Degree$ is empty or not. If it is empty, the algorithm is over, or goes to step (4).

(4) The $flag$ increases by one, the algorithm goes to step (2) until the set $Degree$ is empty.

λ is the threshold we set for the clustering radius and its value had better set referring to the value of K . That is because the correlation and difference of data sets is determined by the value of K .

The results of clustering analysis maybe contain several different statuses. Firstly, all elements in set $Degree$ are in one set such as G_i, which means the sensory data sets have the best correlation and they can be fused directly without any change. Secondly, most elements in set $Degree$ are in one set such as G_j, which means the sensory data sets have good correlation and the algorithm fuses the most elements in set $Degree$ with abandoning the a few data sets of bad correlation. Thirdly, each set $G_1, G_2, ..., G_n$ has some elements of set $Degree$, which means the elements in set $Degree$ don't have good correlation and they can't be fused directly. Clustering analysis diagrams are shown in figure 3.

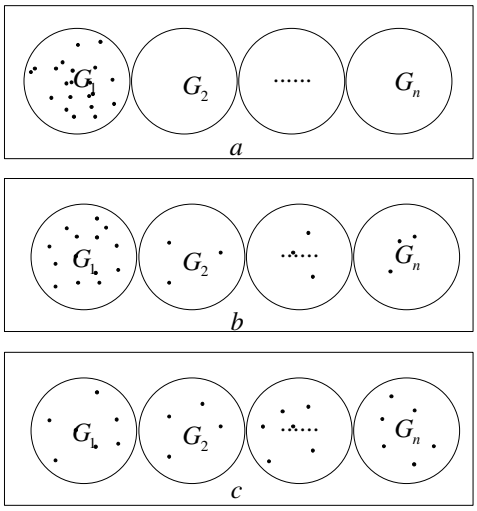

Fig. 3 Clustering Analysis Diagrams

Many reasons will cause the poor correlation of sensory data such as outside disturbances and unreasonable location of sensor nodes. If there are some non-artificial reasons that cause the bad data, the algorithm can use preprocessing mechanism to correct the sensory data. For instance, the data from node A is always higher than that from node B by 2, the algorithm will add 2 to the data from node B so that it can conveniently compute the correlation and fuse the data.

The algorithm also applies the joint probability density function to compute the best point for data aggregation. Supposed that the data from sensor node i obeys the Gaussian distribution $\rho_i(x) = (\mu_i, \sigma_i)$ and the function gets the biggest value at point μ_i for each node. The probability function is $\rho_i(x)$.

$$\rho_i(x)=\frac{1}{\sqrt{2\pi}\sigma_i}e^{-\frac{(x-\mu_i)^2}{2\sigma_i^2}} \tag{5}$$

Therefore the joint probability function is $L(x)$.

$$L(x)=\prod_{i=1}^{n}\rho_i(x)=\left(\frac{1}{\sqrt{2\pi}}\right)^n\frac{1}{\prod_{i=1}^{n}\sigma_i}e^{-\left(\sum_{i=1}^{n}\frac{(x-\mu_i)^2}{2\sigma_i^2}\right)} \tag{6}$$

It is obvious that $L(x)$ has the biggest value at point $\sum_{i=1}^{n}\frac{\alpha_i}{\sigma_i^2}\Big/\sum_{i=1}^{n}\frac{1}{\sigma_i^2}$.

Finally, here analyzes the time complexity of the algorithm and it mainly focus on two aspects. On one hand, the time complexity is the sort on $Degree$, on the other hand, the time complexity is the clustering analysis on sensory data. Here the algorithm adopts the best Quicksort algorithm to sort the elements in $Degree$, so the time complexity is $O(n\log(n))$. In the clustering analysis, the algorithm must scan the sets $G_1,G_2,...,G_n$ whether the set contains elements or not, so the time complexity is $O(n)$. In summary, the time complexity of this algorithm is $O(n\log(n))$. Thus, the complexity is just related with the number of sensor nodes.

Simulations

The simulated data comes from the article [12], as is presented in table 1.

Table 1. The sensory temperature

Sensor Node	Time					
	1	2	3	4	5	6
1	899.5	905.3	904.9	900.6	889.9	899.4
2	898.3	875.9	888.1	886.2	907.5	904.4
3	896.7	906.8	898.2	904.0	896.4	891.6

The real value of temperature is 900°C. Generally speaking, the precision of sensory data is one thousandth. If the sensory data is different from the real value by two thousandth, it's also regarded as normal. If the difference is beyond five hundredth, it's abnormal. The detailed parameters are set in table 2.

Table 2. Parameter

parameter	value
α	0.002
β	0.05
K	0.95
λ	0.9
d_a	10
d_b	10
d_{ab}	5

The simulated results of fusion are presented in table 3. According to the fusion results, the absolute difference is 13.3, which is better than the results of algorithms mentioned in the article [12]. The table 3 shows the fused nodes and the last fused results for six times. However, some parameters set is artificial, if the values of parameters are adjusted, the fused results will be better, but the values of parameters can not easily changed after set.

Table 3. Simulated results

Sensor Node	1	2	3	4	5	6
	$s_1+s_2+s_3$	s_1+s_3	s_1+s_3	s_1+s_3	s_3	s_1
1	899.5	905.3	904.9	900.6	889.9	899.4
2	898.3	875.9	888.1	886.2	907.5	904.4
3	896.7	906.8	898.2	904.0	896.4	891.6
Result	898.8	906.0	900.1	902.0	896.6	899.4

Conclusion

This article proposed an algorithm for data aggregation based on the correlation and clustering analysis, in which contains the correlation's definition and computing and the clustering analysis. The clustering analysis is responsible for judging the overall distribution of sensory data. At last, the algorithm uses the joint probability function to find the best point for data aggregation. Simulations results show that the method is better at fusing performance than other algorithms.

Keywords: SAR; GIS road network; registration; optimization;

Abstract. Synthetic aperture radar (SAR) technique has been widely applied in disaster monitoring and evaluation, because of its all-weather and all-time capability. In particular, the integration of high resolution SAR image and GIS data has been proved to be an effective solution to change detection for rapid disaster response. However, accurate registration of SAR image and GIS data remains a challenging task. On the one hand, SAR image and GIS data are two different representation levels of the real world. GIS data lacks of grey value and texture information, thus traditional use of grey-based and texture-based feature descriptors for feature matching in GIS data is impossible. On the other hand, the extraction of matching primitives is difficult in the SAR image due to the speckle noise. Moreover, though features can be extracted in the SAR image, the matching can be difficult since features may be fractured and missing. In this paper, we propose a new method for vector-to-SAR image registration which utilizes conjugate line-pair intersections as matching primitives. The core idea consists in two aspects: 1) Different from traditional road intersection based registration methods, conjugate line-pair intersections are employed as matching primitive in the proposed method. 2) To find out the optimal set of matching features, a matching technique that using pairwise constraint and the iterative conditional mode (ICM) optimization algorithm is introduced. Experiment results proved the reliability and feasibility of the proposed method.

Introduction

In recent years, the fast development of SAR systems such as TerraSAR-X, Cosmo-Skymed and Radarsat-2 have provided effective means for disaster monitoring and evaluation [1]. Especially, the fusion of SAR image and GIS data has great potentiality and advantage for road damage detection and flood monitoring etc. For example, road objects, especially important roads, are more likely to be static with slow change, thus the existing GIS road network can be employed to identify damaged road quickly and accurately [2]. However, the precise registration of SAR image and GIS data is a significant and essential step. In fact, remote sensing image and GIS data are two different ways to represent the surface objects, where images provide a continuous representation of geographic area and vector data represents objects as discrete entities. In addition, the SAR image suffers inherent speckle noise, which makes it more difficult to extract accurate features from the SAR image. Furthermore, even if features are extracted in the SAR image, the matching procedure tends to be an error-prone process, since many features are short and broken. Thus, accurate registration of SAR image and GIS data remains a challenging task.

The aligning of image and GIS road network requires identifying an appropriate set of conjugate features on the two data sources. Most widely used features are road intersection points, road line segment and road polyline. Song [3] presented an automated geospatial conflation method based on road intersections and terminations. Extracted points were matched by a relaxation labeling algorithm and a refinement algorithm was further applied to obtain better accuracy. However, road intersections were difficult to be identified in the SAR image due to the complexity of remotely sensed images and speckle noise. Liu [4] proposed an automatic registration approach using line segments and a modified Hough Transform. The drawback of the method is the Hough-like voting

strategy makes the algorithm time consuming and noise sensitive. Wang [5] introduced a novel approach to the registration problem based on polyline features and point networks. Topology and geometry of a network was utilized to establish correspondence. However, the process needed user interference to determine the index range of nodes in template construction.

Considering the state-of-the-art in image-to-vector registration, a new method based on conjugate line-pair intersection is proposed in this paper. Firstly, different from traditional road intersection based registration methods, conjugate line-pair intersections are employed as matching primitives in the proposed method. Then, a robust matching technique which using pairwise constraint and the iterative conditional mode (ICM) optimization is introduced to obtain accurate matching result. Pairwise constraint aims to obtain potential corresponding line-pair intersection. The ICM optimization aims to obtain the optimal set of corresponding features. Matched line-pair intersections are regarded as control points to perform transformation between the SAR image and GIS road data.

Methodology

For feature-based methods, one of the key problems is to establish a reliable correspondence between the matching primitives in the reference data and those in the floating data. Since there is no grey value or texture information in the GIS data, affine-invariant line matching [6] and mean-standard deviation line descriptor (MLSD) [7] are no longer suitable for our situation. Thus, in this paper, we investigate the line matching problem only based on the geometric relationship between line-pairs. The proposed method mainly consists in two aspects: 1) searching potential conjugate line-pair using pairwise constraint; 2) locating maximum matching cliques using the ICM optimization.

A) searching potential conjugate line-pair using pairwise constraints

Line-pair intersection is regarded as matching primitive in the proposed method. In order to obtain robust matching primitives, a line-pair must satisfy:

1) The length of each line segment is no lesser than t_l;

2) The angle between the two line segments is no lesser than t_a.

The first restriction limits the participation of non-robust line segments for generating matching primitive. The second restriction limits the generation of erroneous matching primitive from line segments with similar slope. The angle between the two line segments θ is considered as the angle of the current line-pair.

Considering two correspondingly matched line-pairs, it is necessary that the angle difference between two line-pairs is close. Thus, the angle difference can be used to guide pairwise constraint, which is illustrated in

$$\varepsilon_\theta = |\theta_i - \theta_j|, \qquad 0 < \varepsilon_\theta < t_\theta \tag{1}$$

θ_i and θ_j are the i^{th} SAR line-pair and the j^{th} GIS line-pair, respectively. t_θ is the user defined angle threshold.

B) locating maximum matching cliques using the ICM optimization

After using the pairwise constraint, all potential matching line-pairs are obtained. However, due to the angle ambiguity, many-to-many matching line-pairs may exist. Thus, in order to realize the efficient one-to-one correspondence, we should find out the maximum cliques from potential line-pairs to ensure the minimum matching error. Let us assume that the m pairs of potential line-pairs are obtained using the pairwise constraint. Then we have

$$C = \{c_i = (l_{i1}^b, l_{i2}^b, l_{i1}^w, l_{i2}^w, p_i, q_i) \mid i = 1, ..., m\} \tag{2}$$

l_{i1}^b and l_{i2}^b are line-pairs from the SAR image and l_{i1}^w and l_{i2}^w are line-pairs from the GIS data. p_i and q_i are the corresponding line-pair intersection.

In fact, one line-pair in the SAR image may have several potential matching line-pairs in the GIS data. Thus, four matrixes MB, MB_{loc} and MW, MW_{loc} are created to record each line-pair in the potential line-pairs. Assume that there are $N1$ different line-pairs in C from SAR image and $N2$ different line-pairs from GIS data, the matrixes can be defined as

$$MB = [mb_1, mb_2, ..., mb_m], \quad MB_{loc} = [\{loc1\}, \{loc2\}, ..., \{locN1\}]$$
$$MW = [mw_1, mw_2, ..., mw_m], \quad MW_{loc} = [\{loc1\}, \{loc2\}, ..., \{locN2\}] \tag{3}$$

Where $mb_i \in \{1, ..., N1\}$ and $mw_i \in \{1, ..., N2\}$ denote the order of i^{th} line-pair element in C for SAR image and GIS data, respectively. MB_{loc} and MW_{loc} are used to record the exactly locations of i in mb_i and mw_i. Then, we introduce a match matrix M of size $m \times 1$ to describe the match condition of potential matching line-pairs

$$M_i = \begin{cases} 1, & if\ the\ i^{th}\ element\ in\ C\ is\ a\ correctly\ matched\ one \\ 0, & otherwise \end{cases} \tag{4}$$

M should satisfy two-way constraints to ensure one-to-one correspondence,

$$\sum_{i=1}^{m} M_i f(mb_i == j) \le 1, \quad j = 1, 2, ..., N1$$
$$\sum_{i=1}^{m} M_i f(mw_i == k) \le 1, \quad k = 1, 2, ..., N2 \tag{5}$$

where $f(\ )$ is a Boolean function. All possible M can be obtained from the MB_{loc} and MW_{loc}. Firstly, $N1$ pairs of different line-pair from MB_{loc} and $N2$ pairs of different line-pair from MW_{loc} are selected. Then, the same values in $N1$ and $N2$ are considered as a match choice for M, which represents c_i in the same values are correctly matched. All match choices for M form a potential match set called M-set.

From the above definition, the problem of locating the maximum matching cliques can be solved by minimizing the following energy function,

$$[\hat{M}, \hat{T}] = \arg\min_{M,T} E(M, T),$$
$$E(M, T) = \sum_{i=1}^{m} M_i \| p_i - Tq_i \|^2 / \sum_{i=1}^{m} M_i \tag{6}$$

To solve the optimization problem, the ICM (Iterative Conditional Modes) algorithm is applied. In fact, the goal of the minimization of (6) is to simultaneously find the optimal transformation T model and the optimal match matrix M. Once the match matrix M is found in advance, the transformation matrix T will be determined using the least square method. Finally, weighted graph transformation matching (WGTM) [8] is used to check wrong pairs in the final matching primitives. The remaining corresponding points are used to produce the final registered data.
The pseudo-code of the ICM optimization algorithm is listed below.

Algorithm 1: The ICM algorithm

Initialize the match matrix M by selecting the first component in M-set.
$k=0$; $E_0 = E(M_0, T_0)$;
Begin A: (Do A until all components in M-set are checked)
1 Select the next component in M-set, and calculate the energy $E_{k+1}(M_{k+1}, T_{k+1})$;
2 Update the minimum energy $E_{min} = min\ (E_k, E_{k+1})$;
3 $k=k+1$;
End A.
$E=E_{min}$;
WGTM algorithm is applied.
End Algorithm 1.

Experiment and Analysis

In this section, we illustrate the proposed method on real SAR image and GIS data to demonstrate the effect of the proposed registration method. The reference image is a TerraSAR-X image (spatial resolution: 1m), which is captured on 2012 with a size of 3850×3169 pixels. The GIS data is downloaded from http://www.openstreetmap.org/ with a free charge. In the experiment, road line segments are detected using the Snake method [9], which has been widely used for road detection in SAR images. However, a well-known problem of active contour model is that it requires very good initialization. Thus, in order to provide a good initial estimation of the road location for SAR image, the GIS data is approximately aligned with the SAR image using a single manually selected tie point.

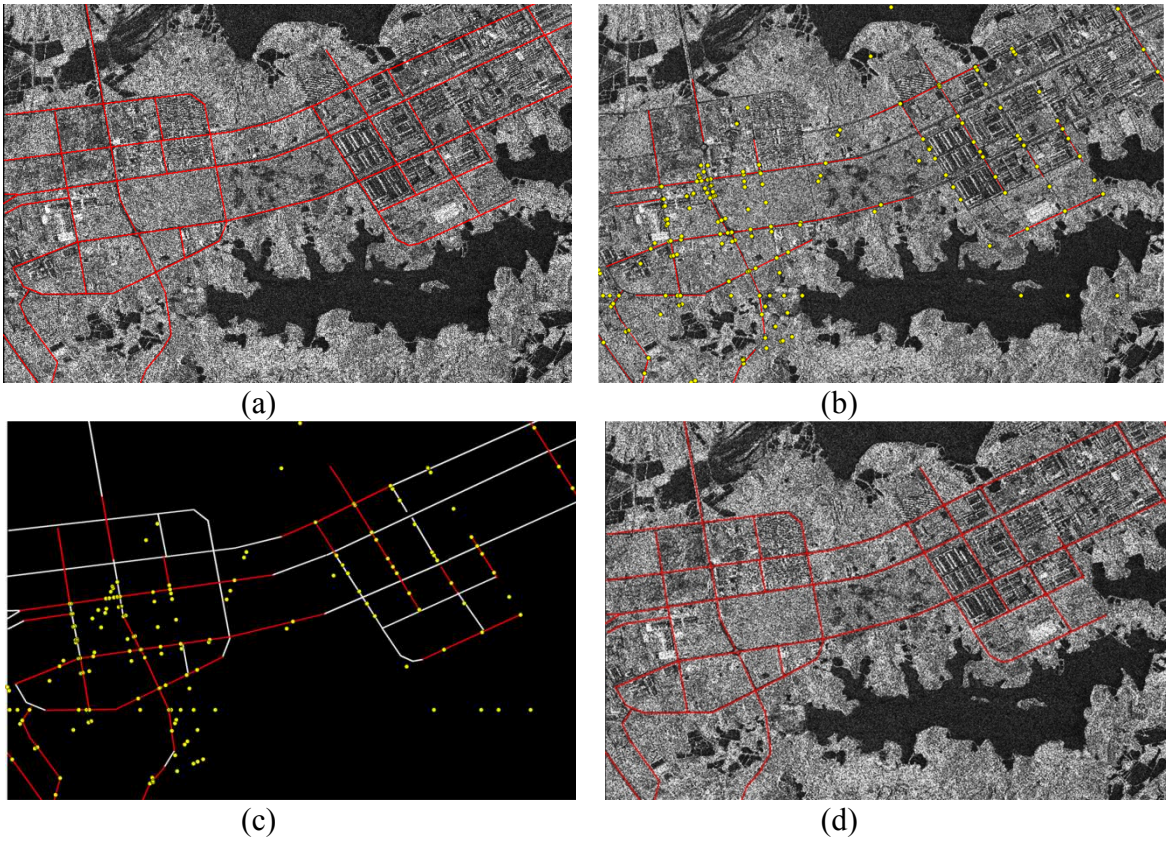

Fig.1. The experimental results. (a) Initial alignment using a single tie point; (b) Matched line-pair road segments and intersections in the SAR image; (c) Matched line-pair road segments and intersections in GIS data; (d) Final alignment using the proposed method.

From the above Figure 1(a), we can see that the SAR image and GIS data are approximately aligned; however, there is an obvious displacement in the right part of the image. (b) and (c) shows the matched road line segments and the corresponding points. 162 pairs of corresponding points are obtained using the proposed method. (d) shows a desired alignment between the SAR image and GIS data using the proposed method.

To evaluate the proposed matching method, the proposed method is compared with two line segment matching algorithms: Modified Hough Transform (MHT) [4], Gaussian Mixture Models and Expectation-Maximization (GMM-EM) [10]. The comparison results are given in Table I. 20 pairs of corresponding tie points are manually selected as a reference for RMSE assessment.

Table I: Comparison of the proposed method with other line segment matching algorithms

Algorithm	*Total matching primitives*	*RMSE*
Our	162	1.56m
MHT	30	11.32m
GMM-EM	32	2.12m

Conclusion

In this paper, we presented a novel high-resolution SAR image and GIS data registration method based on pairwise constraint and the ICM optimization. This technique uses the pairwise constraints to obtain potential matching line-pairs. Then, the ICM optimization is applied to obtain the optimal matching line-pairs for robust registration. Experiment shows that the proposed method is feasible and could achieve high accuracy.

Keywords: Low Contrast Road; Remote Sensing; Road Extraction; Gabor Filter; Phase Grouping; Simulated Annealing

Abstract. High-resolution satellite remote sensing image are mostly used for accurate updating of GIS data. As the primary GIS data, urban roads on the image show the rich geometric features and radiation characteristics, that edge detection and grouping becoming an important way to solve the road extraction. However, edge elements obtained from images are always discontinuous for interference of noise and weak contrast between road and background. What more, vehicles, plant, buildings and shadow blocking results in weak grouping relation of elements. In processing, insignificant candidate road may be weeded out as noise and lead to failure road extraction. This paper presents a semi-automated extraction method for low contrast road basing on statistical grouping of orientation texture feature. Multi-direction and multi-scale Gabor filters are employed to detect directions of road texture. Then same direction pixels are grouped under constraining of rectangle template and generate road base elements. Finally, simulated annealing algorithm is used to optimize elements connection. Experiment results show that proposed method was effective in accurate extraction of low contrast road.

Introduction

Road extraction in urban areas is an important task for updating geographic information. Especially in recent years, the rapid development of urban areas makes it urgent to provide up-to-date road maps. Due to high spatial resolution (1 to 4 m), fast orbit repeatability, rich multi-spectrum information and stable, affordable acquisition cost, remote sensed images have been taken as the main data source for road extraction.

Via the research and development of several decades, various methods or models were proposed. In general, most methods of roads extraction are divided into three levels that are base features extraction in low level, characteristic analysis and selection in middle level, objects understanding and identifying in high level due to computer vision theory of Marr [1]. Rule or knowledge-based methods [2] is so called 'high level' processing in order to group and link line features detected in 'low-level' or 'intermediate level' processing. Whereas, well performed lines detection is the key of successful road extraction. As the basis for extraction method, it is assumed that spectral properties of roads are limited to a fixed range [3] and roads have good contrast with its adjacent areas [4]. However, in high-resolution images, roads may be hidden or not visible, and their surrounding environments are very complex [5], especially in urban areas, where objects like zebra crossings, vehicles, trees, building and shadows cause noises and reduction of contrast between roads and background. As a result, road extraction methods based on edge features are confronted with great difficulties.

Gradient is most considered in edges detection methods. Typically, phase grouping [6] is taken as an effective method for extraction of low contrast edges and it was used to extract roads with no clear and continuous boundaries in RS images in [7]. However, dramatic change of pixel value, complex noise of background, and density of edge features in high resolution images make it difficult to generate effective line support region. Therefore, it is hard to achieve better edge detection results under complex scene with methods basing spatial domain characteristics. As one

of the characteristics of material energy, spectrum in frequency domain has the unique advantages in description of edge [8] and texture [9] feature. Wu [8] proposed a method of edge feature detection from high-resolution remote sensing images based on frequency spectrum zone energy. In [10], Gabor filter was used for road lane marking extraction. Considering obvious directivity of texture feature of pavement, Moghadam [11] employed Gabor filters to detect vanishing-points in unstructured roads.

In this paper, the major problem to be overcome is center line detection of low-contrast urban roads in high resolution images. Fully considering the advantage of phase grouping in edge detection, and Gabor filter in road texture direction analysis, we propose a center line detection method of low-contrast urban roads based on statistical grouping of orientation texture feature. Firstly, road image is filtered using six-directional Gabor filter at multi-scale. Then, pixels directions are determined according to the response in each direction-filter. Line support regions are constructed basing on co-directional pixels. Considering geometric feature of urban roads, line support regions are constrained as rectangle with large ratio of length to width. These line support regions are taken as road base elements. Finally, assuming that road center line is consisted of polylines, and optimizing road center line using simulated annealing algorithm.

Methodology

The conceptual workflow of the proposed method consisted of four steps: direction feature detection; road base element extraction; optimization of road center lines. They are described in details below.

Directional Feature Detection with Gabor Filter. The 2D Gabor filter [9] has been successfully applied to a variety of image processing and pattern recognition problems, such as texture analysis [12], object detection [13] and image segmentation [14].

In this paper, Gabor filter is used to detect the direction feature of road texture. Considering the variance of road width, multi-scale texture response is needed to be considered. In the processing of texture extraction, multi-scale and multi-orientation Gabor filters is taken convolution with image by sliding window.

The Gabor filter function is shown as formula (1).

$$g(x,y;\omega,\varphi)=\frac{\omega}{\sqrt{2\pi}c}e^{\frac{-\omega^2(4a^2+b^2)}{8c^2}}\left(e^{ia\omega}-e^{\frac{-c^2}{2}}\right) \quad (1)$$

Where, φ denotes direction of texture, ω represents scales, a is equal to $x\cos\varphi+y\sin\varphi$, b is equal to $-x\sin\varphi+y\cos\varphi$, c is equal to $\frac{\pi}{2}$.

To determine texture direction, the conventional approach is choosing the maximum energy response as amplitude of corresponding pixel texture feature, and corresponding filter direction as the direction of pixel texture. However, there some opinions show that texture response detected by Gabor filter is not stable in some cases, i.e. the image pixel differences may lead to relatively large phase differences.

In order to obtain stable and reliable direction information of texture, it is calculated by weighted average according to each direction. Corresponding weights are determined by normalized texture amplitude of each direction.

Extraction of Road Base Elements. In complex scenes, pixels direction features are shown inconsistent within local areas that it is impossible to obtained significant linear road elements directly. Using the orientation grouping method, pixels are classified into eight groups according to predetermined directions that dividing the circle into eight equal parts. Then line support regions are detected from grouped pixels and it makes a great reduction of the interference coming from background.

In the process of semi-automatic extraction, several seed points are needed by manually selection. It is required that seed points are located in significant road corners. The general direction of road can be obtained based on input seed points. So there is no need to group pixels into

8 directions like phase grouping method. Our processing focuses on grouping pixels which have approximate directions with known direction. The difference of direction should be kept in specify angle threshold. Removing pixels with weak response that their amplitudes are less than given threshold, it generates original support regions consisted of co-directional pixels which are mutually connected.

Considering the geometrical characteristic, urban roads are mostly shown as long rectangular in images. Even if in the non-straight roads, local segments can be regarded as rectangular approximately. Here, rectangular template is used to detect line support regions from the original support regions under shape constraint. Each line support region is a candidate for a road base element.

Optimization of Road Center Line. It is a route optimization problem to detect road center line from base element. We suppose the seed points at both ends of the path as the starting and ending points. Route is consisted of base elements and joint lines. Target function is defined according to geometric and spectral characteristics of road. Simulated annealing algorithm is employed to search the optimal route which has the minimal target function value.

The definition of target function should take into account of the following factors: length of the path; variance of pixel value in route; direction variance of base elements and joint lines. The definition is shown as formula (2).

$$T_r(i) = a(l_i - l_{min})/l_{min} + b\sigma_{gray}/256 + c\sigma_{direct}/180 \quad (2)$$

Where, l_i denote length of the i-th route; σ_{gray} and σ_{direct} denote the Standard Deviation of pixel values and elements direction respectively. a, b, b represent corresponding weight coefficient respectively.

Acceptance principle of new route is according to Metropolis principle [15]. While target function value of new route is less than that of current optimal route, it is accepted as new optimal route. Otherwise, new path is accepted with probability of state transition. Finally, global optimal route is obtained by the model convergence. To remove rags, smoothing is carried out on route and the result is the final extraction results of road centerline.

Experiments

This section highlights the experiments performed based on the proposed algorithm. The image considered for experiment comes from QuickBird and it consisted of R, G, B bands (see Fig.1 (a)). Considering the average width of road, the scale of Gabor filter is set to be 0 and 1, while the direction parameters are set to be 0, 30, 60, 90, 120, and 150 respectively.

The road feature extraction result for experiment is shown in Fig.1 (b)-(c). Test image is used in contexts of urban, that roads are relatively straight, and with more obstructions from shadows, trees and vehicles. The proposed method does not consider the contextual information explicitly. From the filtered image, it is obviously that road in specify direction are prominent and backgrounds are well suppressed. Extraction results of base elements also show the robustness of proposed method.

Fig.1. (a) Original image. (b)-(c) Filtered image with direction 120 and scale 0 to 1. (d) Extracted road base elements. (e) Extraction results of proposed method. (f) Hand-drawn reference road map

Fig.1 (e) shows the final extraction results. The proposed method has been evaluated based on comparing with hand-drawn reference road map (Fig.1 (f)). In general, main roads in image were extracted. Whenever roads are affected by minor anomalies (e.g., tree, shadows), the road centerlines are correctly extracted.

Conclusions

In this paper, we have presented a new approach to extract center lines of low contrast road in high-resolution aerial images over urban areas, based on multi-scale Gabor filtering and direction grouping. The direction of texture properties of road are effectively taken into account. The image is first filtered in different scale and direction. Then adjacent pixels with certain direction homogeneity and linearity in the structure are marked as line support regions. Regions which can surely be judged as non-road areas are eliminated by statistic distribution. Road base elements are generated from remaining support regions. In the post-processing step, optimal route of base elements connection is obtained using simulated annealing algorithm. The method is simple and not sensitive to noise and scene objects. It is specific for low contrast or strong interference roads in high resolution images. The future perspective is to make the processing more automatic without inputting seeds. Considering the variance of roads width, filter scale has to be adaptive for extracting salient direction features of roads.

Keywords: PSO; expansion model; multi-threshold; image segmentation

Abstract. Both maximum entropy method and Particle swarm optimization (PSO) are common threshold segmentation methods which have been used not only in image segmentation, but also in multi-threshold segmentation. Maximum entropy method is time-consuming, PSO may easily get trapped in a local optimum. In view of this concerning issue, we propose the PSO and maximum entropy are combined to make improvements on the PSO introduced in expansion model and opposition-based module. The objective functions of the maximum entropy as well as the PSO are obtained, which have improved to optimize them and search the optimal threshold combination, to achieve multi-threshold image segmentation. The results demonstrate that the new algorithm improved the segmentation speed and enhanced the robustness. And the optimizing results are stable.

Introduction

Segmentation is a critical task in image processing. Image segmentation refers to dividing images into several meaningful areas according to some image features and making the features show similarity in one area and differentia in other areas. Threshold segmentation method is applied wildly in image segmentation and this method assumes that different objects in an image could be distinguished by gray value. So the key to this method is how to determine the threshold. Threshold method can be subdivided into the maximum entropy method, Otsu method and minimum error threshold method. However, these methods are initially only based on one-dimensional histogram and affected by the noise evidently. The maximum entropy method is little influenced by the target size, it can produce good segmentation results for images with different size and noise ratio of signal.

The maximum entropy threshold method proposed by Kapur that has been proved as an efficient method in image segmentation for single threshold. However, The calculation speed becomes greatly slow, which is difficult to meet the requirements of practical application of. Therefore its application is restricted. Recently, a new variant of esophageal atresia (EA), known as particle swarm optimization (PSO) [1], which is inspired by the emergent motion of flock birds searching for food, has been developed, mainly due to its simplicity, superior convergence characteristics and high solution-quality. PSO has become one of the most popular optimization techniques for solving optimization problems in systems, such as artificial neural network training, fuzzy system control, system optimization, control field and others. Particle swarm optimization algorithm has many advantages, but it declines rapidly in the late convergence. A characteristic of falling into local optimum easily makes the particle swarm algorithm often unable converge to the global optimal [2].

Document [3] illustrate the threshold segmentation based on particle swarm optimization, in the literature [4] describe the optimization object function by maximum entropy or Otsu method. The objective function is optimized by particle swarm optimization algorithm to achieve the optimal threshold segmentation. Taking advantage of the high efficiency of the particle swarm optimization algorithm, the literature [5] presents a method to solve multi-objective optimization problems using particle swarm optimization. The literature [6] respectively proposes a modified PSO for the global optimization of multimodal functions. But it is not fully solve the local optima, precocious and multi dimension problems.

In this paper, based on the advantages and disadvantages of the maximum entropy algorithm and particle swarm algorithm, a new algorithm is presented to improve the particle swarm algorithm and maximum entropy methods. An optimized objective function is obtained by the maximum entropy method. To obtain the initial candidate optimal solutions in the process of initializing population, opposition-based learning theory has been used. Introduction an expansion algorithm to restrain premature and to avoid local optimum, making up for the shortcomings of particle swarm algorithm and solving the problem of slow speed calculation of maximum entropy threshold. The algorithm achieves good segmentation results.

Related algorithms

Multi threshold segmentation based on maximum entropy. In this section, the maximum entropy based on threshold technique is introduced. Let the gray levels of a given image of N pixels range over [0, l-1]. The image with threshold is divided into two forms: target (A) and background (B). Let $P_t = \sum p_i$ ($0 \leqslant i \leqslant t$) Where p_i is the probability of gray appearance. Therefore maximize entropy is:

$$H_{(t)} = H_A + H_B = -\sum_{i=0}^{t} \frac{p_i}{P_t} \ln \frac{p_i}{P_t} - \sum_{i=t+1}^{l-1} \frac{p_i}{1-P_t} \ln \frac{p_i}{1-P_t} \tag{1}$$

The optimal threshold t^* can be obtained by maximizing $H_{(t)}$: $t^* = \text{argmax } H_{(t)}$ (2)

It can be extended to the multilevel threshold case with k thresholds as follows:

$$H(t_1, t_2, \ldots, t_k) = -\sum_{i=0}^{t_1} \frac{p_i}{P_{t_0}} \ln \frac{p_i}{P_{t_0}} - \sum_{i=t_1+1}^{t_2} \frac{p_i}{P_{t_1}} \ln \frac{p_i}{P_{t_1}} - \ldots - \sum_{i=t_k+1}^{l-1} \frac{p_i}{P_{t_k}} \ln \frac{p_i}{P_{t_k}} \tag{3}$$

The optimal thresholds (t_1^*, $t2^*$,..., tk^*) by maximizing $H(t_1, t_2,..., t_k)$: $t_1^*, t_2^*, \ldots, t_k^* = \text{argmax } \{H(t_1, t_2,..., t_k)\}$. Where, $0 \leq t_1 \leq t_2 \leq \ldots \leq t_k$. So, using the maximum entropy threshold method, multi threshold image segmentation problem can be summed up as the best threshold value of the optimization problem, where, $t^* = \{t_1^*, t_2^*, \ldots, t_k^*\}$.

In bi-level threshold, Kapur method can be utilized to find the optimal threshold efficiently. However, for the multilevel threshold problem, Kapur method has a disadvantage that the computational time will be very expensive due to the exhaustive search. In order to search the best threshold combination quickly and accurately, and make the image segmentation result more accurate, the improved particle swarm algorithm is applied to image segmentation. Such algorithm is used to find the optimal threshold combination and make the segmentation results accurate.

The basic principle of particle swarm algorithm. PSO is an algorithm inspired by bird-flocking and fish-schooling. Let x_i denote the particle's position and v_i is the corresponding velocity. In N-Dimensional search space, at iteration k, each particle i has its position and velocity defined by: $X_i^k = [X_{i,1}, X_{i,2}, \ldots, X_{i,N}]$, and $V_i^k = [V_{i,1}, V_{i,2}, \ldots, V_{i,N}]$

Velocity and particle updating are done using the following equations:

$$V_{i,n}^{k+1} = w \times V_{i,n}^k + c1 \times Rand()(pbest[i] - X_{i,n}^k) + c2 \times rand()(gbest - X_{i,n}^k) \tag{4}$$

$$\begin{aligned} X_{i,n}^{k+1} &= X_{i,n}^k + V_{i,n}^{k+1}, \quad \text{if } X_{min} \leqslant X_{i,n}^{k+1} \leqslant X_{max} \\ &= X_{min}, \quad \text{if } X_{i,n}^{k+1} < X_{min} \\ &= X_{max}, \quad \text{if } X_{i,n}^{k+1} > X_{max} \end{aligned} \tag{5}$$

Where, $i = 1,2,\ldots..$, M (M is the swarm size) ; $n = 1,2,\ldots..$, N;

In equation (4), *rand*() is a random number, *pbest* represents best position of a particle & *gbest* represents best of all *pbest* values. *c1* is cognitive parameter and *c2* is social parameter.In equation (5), X_{min} and X_{max} represent minimum and maximum values of particle positions respectively. Inertia weight w, which is an important parameter for PSO's convergence, is varied as:

$$w = w_{max} - \{(w_{max} - w_{min}) \ / iter_{max}\} \times iter \tag{6}$$

Where, w_{max} and w_{min} are the initial and final weight respectivel*ter* is the current iteration and $iter_{max}$ is the maximum number of iterations. This ensures that at the start of the algorithm, each particle further detects the good seed in the global scope; Later, the smaller value of w ensures that the particles

perform fine search in around the pole, the algorithm has a certain probability to converge to the global optimal value.

The initialization of the particle space: A good choice in selecting particle's spatial initialization will greatly reduce the convergence time. Random generation of particle group of a certain size sets the particle's initial position and velocity.

In the iterative process, the particle is closing to the optimal direction continuously. When meeting the local optimum, all particles' velocity quickly is reduced to zero, the particle becomes stagnant, and the emergence of the phenomenon of premature converges.

The improved particle swarm algorithm.

The introduction to opposition-based learning and expansion model. PSO is a relatively new optimization algorithm that has been applied to a variety of problems. However, it may easily get trapped in the local optima when solving complex multimodalproblems. In addition, to enhance the global convergence, when producing the initial population, opposition-based learning method is employed. Since 2005, opposition-based learning is a fast growing research field in which a variety of new theoretical models and technical methods have been studied for dealing with complex and significant problems. When evaluating a solution x to a given problem, simultaneously computing its opposite solution will provide another chance for finding a candidate solution which is closer to the global optimum.

Opposite number: let $x \in [a,b]$be a real number. The opposite of x is defined by: $x^* = a+b-x$ (7)

Similarly, the definition is generalized to higher dimensions as follows:

Opposite point: let $X=(x_1,x_2,\ldots,x_N)$ be a point in a N-dimensional space, where $x_1,x_2,\ldots,x_N \in R$ and $x_j \in [a_j,b_j]$, $j \in 1,2,\ldots,N$. The opposite point $X^*=(x_1^*,x_2^*,\ldots,x_N^*)$ is defined by: $X_j^* = a_j+b_j-x_j$ (8)

By applying the definition of opposite point, the opposition-based optimization can be defined as follows.

Opposition-based optimization: let $X=(x_1,x_2,\ldots,x_N)$ be a point in a N-dimensional space (i.e., a candidate solution). Assume $f(x)$ is a fitness function which is used to evaluate the candidate's fitness. According to the definition of the opposite point, $X^*=(x_1^*,x_2^*,\ldots,x_N^*)$ is the opposite of $X=(x_1,x_2,\ldots,x_N)$. If $f(X^*)$ is better than $f(X)$, then update X with X^*; otherwise keep the current point X. Hence, the current point and its opposite point are evaluated simultaneously in order to continue with the fitter one. Opposition based initialization reduces the time of particle swarm optimization in a certain extent and improves the precision and efficiency of the particle swarm search.

Expansion model refers to the particle goes forward and keep the direction of motion, but the motion of a particle changed expansionary in space. For example, A particle from the point A (1,1,1) to B (2,2,2) in 3D space with mandatory expansion. The corresponding formulas of changing the position was: $x(i+1)=x(i)+x(i)$, $x(i+1)=x(i)+a*x(i)$ is used in this paper, where a is the expansion factor.

Multi threshold segmentation based on improved particle swarm optimization.

In this paper, the maximum entropy threshold method is introduced into the improved PSO algorithm. Concrete steps of the algorithm are as follows:

a)The first, all the particles are opposition based initialization, and then in the range of [0，255] random sets the initial velocity, the initial position, *pbest* and *gbest* of the particle.

b)Make the position of the integer, evaluate the fitness value of each particle, According to the principle of multi threshold segmentation based on maximum entropy, the formula (3) objective function is calculated for each particle. On the basis, if it is better than *pbest*, the current position replaced *pbest*, if at all the particles *pbest* is superior to *gbest*, *pbest* will be set in the new *gbest*.

c)Change the particle's velocity and position according to the formula (4) and (5), they are used to check the position and velocity whether they are within the allowed range. There is another situation, when the optimal solution is constant, which has a need for expansion on the location, using the expansion model presented in this paper.

d)According to the termination condition, if reaching the maximum number, the iterations stops; if not, then it returns to step 2 to iterative optimization.

Experimental results and analysis.

Using this algorithm to Lena image (256 × 256) segmentation, and compared to the maximum entropy segmentation, maximum between class segmentation, 2D maximum entropy threshold segmentation, and multi-threshold image segmentation based on the particle swarm of maximum between class method, As shown in figure 1. Figure 2, 3 are for the simulation results of the improved algorithm for high SNR and low SNR image segmentation and the additive noise segmentation. Table 1 is the comparison of several algorithms for the segmentation performance.

Figure (f)	Multi-threshold image segmentation based on improved particle swarm optimization and maximum entropy method	3,95,120,164,263	1.490

It has been seen from the experimental results and table 1, Fig. 1 (b) in maximum entropy image segmentation by histogram to select the threshold value, although it has obtained the better effect of segmentation, but it tends to get high threshold. the segmentation effect is not good; Comparing Figure 2 and figure 3 Results, the traditional maximum between class segmentation graph (c) is the optimal threshold method a basis of uniformity measurement. This method of image for high SNR has greatly good segmentation effect, but for the low SNR is not ideal; Fig. (d) the image threshold segmentation of 2-D maximum entropy method is too long, it is difficult to meet the needs of real-time [7]; Graph (e) combining the maximum between class variance method with particle swarm optimization; for graph (c), maximum between class method have significant effects on the single threshold value segmentation. But for the multi-threshold segmentation, which is complexity and time-consuming; Map (f) represents 5 threshold segmentation, Figure (f) segmentation is more subtle than figure (e) segmentation, good robustness, and the particle swarm optimization, the speed of segmentation is improved, and the algorithm for the image (Fig. 2,3) of different signal to noise ratio have better segmentation effect, it has a wide application range.

Conclusions

Based on improved particle swarm multi-threshold segmentation, the characteristics of the particle swarm algorithm can be taken full advantages. The introduction of opposition-based learning, which is a better solution to excessive computing multi-threshold segmentation problem. Avoid the particle swarm falling into local minimum, the algorithm of this article introduced expansion model and combined with the maximum entropy algorithm. Avoid the maximum entropy threshold is too high, and make the split failure. Experimental results show that the proposed method is simple, fast, good robustness and easy to fall into local minima, etc. It is suitable for multi-threshold image segmentation.

Keywords: Speech Enhancement, EMD, Wavelet Threshold, Noisy Environments

Abstract. Speech enhancement is crucial for speech recognition accuracy. How to eliminate the effect of the noise constitutes a challenging problem in speech processing. This paper presents a new technique for speech enhancement in a noisy environment based on the empirical mode decomposition (EMD) algorithm and wavelet threshold. With the EMD, the noise speech signals can be decomposed into a sum of the band-limited function called intrinsic mode functions (IMFs), which is a zero-mean AM-FM component. Then wavelet threshold of the IMF components can be used to eliminate the effect of the noise for speech enhancement. Experimental results show that the proposed speech enhancement by de-noising algorithm is possible to achieve an excellent balance between suppresses noise effectively and preserves as many target characteristics of original signal as possible.

Introduction

Reliable speech enhancement is a crucial preprocessing step in many speech recognition technologies and is essential in most analysis and synthesis system. The goal of speech enhancement is to identify the important voice of an audio segment for further processing, such as speech recognition, speech coding and communication [1].

Commonly the frequency band of noise is wide that of original signal is limited and mainly lies in low frequency bands. How to eliminate the effect of the noise constitutes a challenging problem in speech processing. Speech enhancement algorithms have been developing considerably. Many algorithms have been reported for solving the speech enhancement problem. In early speech-enhancement algorithms, Spectral subtraction (SS) method is to suppress the additive noise which has been the most widely used for the speech enhancement. However, the performance of speech enhancement by SS-based algorithms is not very satisfactory under noisy environments [2].

In this paper, we use a new technique called the empirical mode decomposition (EMD) has recently been introduced by Norden E. Huang et al. in 1998. This technique adaptively decomposes a non-stationary signal into sums of zero-mean amplitude modulation frequency modulation components. This method has quite good characters to analyze non-stationary signal and nonlinear signal. In most of the existing algorithms the Fourier transform or wavelet transform are used in signal decomposition. The speech decomposition is performed by fitting some predefined bases without satisfying its non-stationary nature. The idea behind EMD method is to decompose non-stationary signal into a number of basis function termed intrinsic mode functions. The speech signal is decomposed using EMD into the data adaptive bases up to the level of fundamental oscillations [3].

In this paper, a new speech enhancement method based on the empirical mode decomposition (EMD) algorithm and wavelet threshold is proposed. The basic principle of wavelet de-noising is to identify and zero out wavelet coefficients of the speech signal, which are likely to contain mostly noise. By identifying and preserving significant coefficients, wavelet thresholding preserves important high-pass features of the speech signal. We also compare this method with other traditional de-noising method, namely SS method, to validate the enhanced characteristics of this method to speech processing.

Empirical Mode Decomposition

The EMD methods will generate a collection of intrinsic mode functions. Given a signal $x(t)$, identify local maxima and minima, Then generate the upper envelope $x_u(t)$ and the lower envelops $x_l(t)$ by connecting the maxima and minima separately with cubic spline interpolation. Then the mean of the two envelops is denoted as:

$$m_1(t) = (x_u(t) + x_l(t))/2 \tag{1}$$

Thus, the first IMF $h_1(t)$ is obtained as:

$$h_1(t) = x(t) - m_1(t) \tag{2}$$

We can repeat this sifting procedure k times, until h_{1k} is an IMF, that is

$$h_{1k} = h_{1(k-1)} - m_{1k} \tag{3}$$

Then, designate h_{1k} as c_1

$$c_1 = h_{1k} \tag{4}$$

where c_1 is the first IMF of the original signal. We can separate $c_1(t)$ from the rest of the data by:

$$r_1(t) = x(t) - c_1(t) \tag{5}$$

Note that the residue $r_1(t)$ still contains some useful information. We can therefore treat the residue as a new signal and apply the above procedure to obtain:

$$r_N(t) = r_{N-1}(t) - c_N(t) \tag{6}$$

The sifting process will be continued until the final residue $r_N(t)$ is a constant, a monotonic function, or a function with only one maxima and one minima from which no more IMF can be derived. Combining the equations in (5) and (6) yields the EMD of the original signal:

$$x(t) = \sum_{i=1}^{N} c_i(t) + r_N(t) \tag{7}$$

The result of the EMD produces N IMF and a residue signal. It is observed that higher order IMFs contain lower frequency oscillations than that of lower order IMFs. If we interpret the EMD as a time-scale analysis method, each IMF reflects the characteristic of each scale, which shows the intrinsic mode characteristic of non-stationary and nonlinear signal.

Choice of Thresholding

In wavelet de-noising, it is common practice to use a soft thresholding function, where the coefficient is slightly reduced even when it is not set to zero. Under certain statistical assumptions, soft thresholding can result in slightly greater noise reduction [4]. The general soft-thresholding function is defined by

$$W_{out} = \begin{cases} \left(\dfrac{W_{in} - T_1}{\max(W_{in}) - T_1}\right)^P W_{in} & W_{in} > T_1 \\ 0 & |W_{in}| \le T_1 \\ \left(\dfrac{W_{in} + T_1}{\min(W_{in}) + T_1}\right)^P W_{in} & W_{in} < -T_1 \end{cases} \tag{8}$$

Its function is also illustrated in Fig. 1.

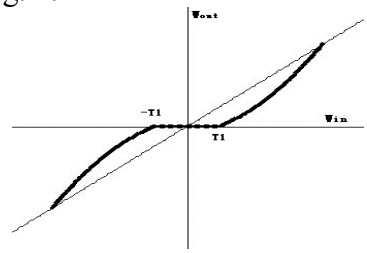

Fig. 1 Soft-thresholding function $0 \le p \le 1$, when p=0, function is corresponding to hard threshold.

The best thresholding in a wavelet basis is achieved when the threshold is adapted spatially and with scale. Here, we use a scale-adapted threshold that is proportional to an estimate of the noise standard deviation. The proportionality factor is explored experimentally. The threshold level in each sub-band is selected as $\sigma_j \sqrt{2\log N_i}$, where σ_j is the median absolute value of the coefficients in the sub-band and N_i is the length of the coefficients. As to white noise, its power is mainly concentrated in first level detail coefficient, and the noise level decreases with the increase of j , so the mean square white noise can be estimated with the each level coefficient $\sigma_j = \beta \cdot median(|D_{j,k}|)$, where β is a constant.

Experiments and Results

The experiment signal is a pure speech signal is shown in Fig.2. The sampling frequency is set to 10 kHz with 16-bit amplitude resolution. The noised experiment data is the pure speech signal in Figure 1 corrupted by white noise and SNR=7.5dB. The noised speech signal is shown in Fig. 3.

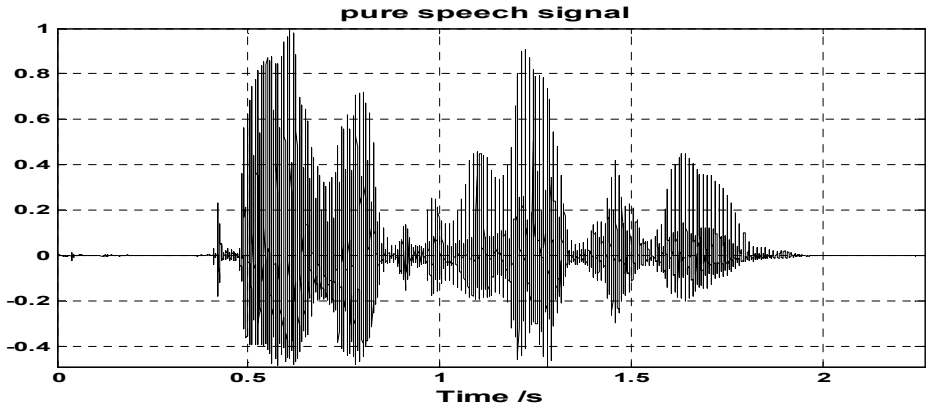

Fig. 2 The pure speech signal

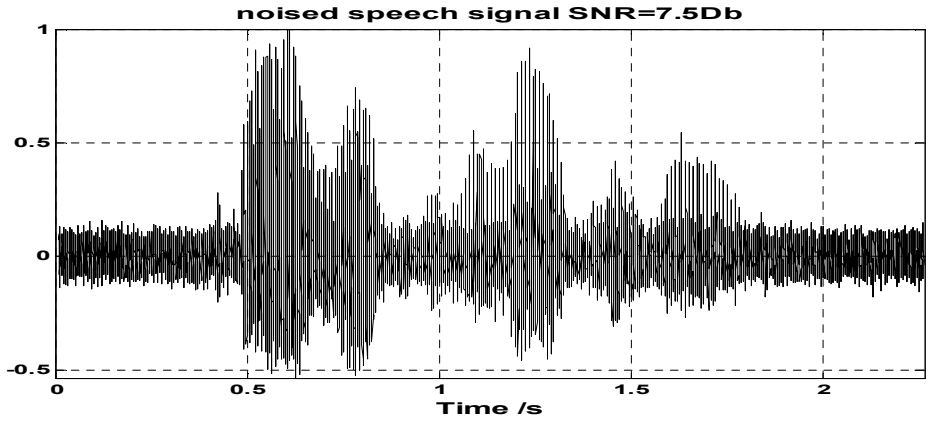

Fig. 3 The noised speech signal corrupted by white noise and SNR=7.5dB.

The noise removal procedures are as follows: (1) Decompose the noised original signal to IMFs by the EMD method; (2) Remove the IMFs whose content belongs to the noise on the base of the sudden increase of its amplitudes; (3) Reconstruct the signal with the rest of IMFs.

Figure 4 shows the result using the spectral subtraction speech enhancement method. Figure 5 shows the result using the proposed speech enhancement method. The experimental results illustrate the newly proposed speech enhancement method is effective.

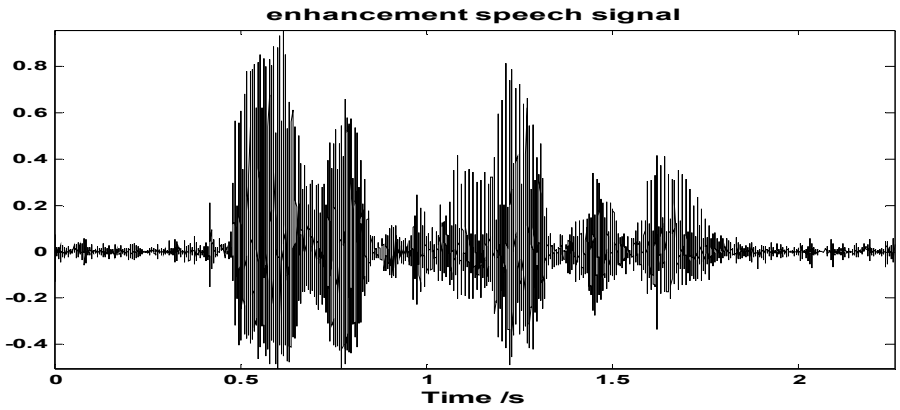

Fig.4. The result using the spectral subtraction speech enhancement method

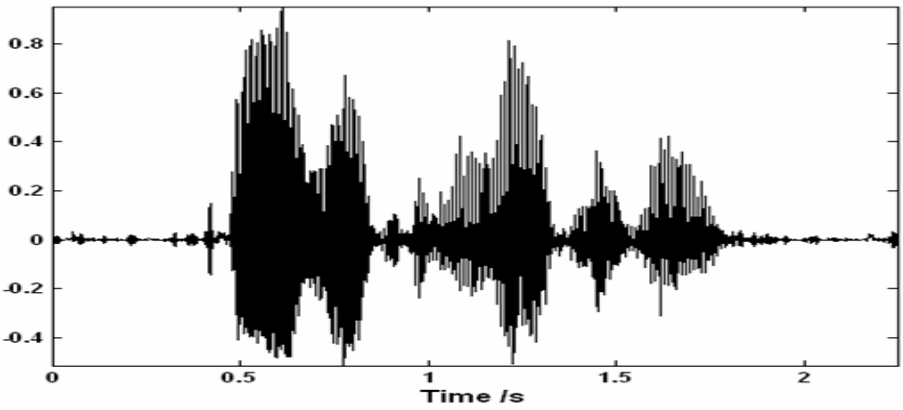

Fig.5. The result using the proposed speech enhancement method

Conclusion

In this paper, a method based on the empirical mode decomposition (EMD) algorithm and wavelet threshold is proposed to speech enhancement of a speech signal embedded in noise. The EMD is well adapted to non-stationary signals and has an excellent time resolution. The EMD and wavelet threshold gives good speech enhancement of a speech signal corrupted with noise. Our experiments show the proposed method can accurately extract the speech signals in differently background noises.

Keywords: peak to mean ratio; OFDMA; SC-FDMA; uplink; emission efficiency

Abstract: In order to reduce peak to average power ratio (PAPR) higher of OFDMA problems, this paper proposes a power line communication system based on SC-FDMA model, compared this model and OFDMA system on peak to average, the same power with the throughput, the same throughput required simulation sub carrier number of needed power and power rate users; The results show that: when introduced the SC-FDMA into the power line communication, can effectively reduce the system PAPR, the terminal can obtain better emission efficiency.

Introduction

Orthogonal frequency division multiplexing access (OFDMA) as the current mainstream technology of power line communication system, Frequency selective fading caused by insufficient to overcome effectively in communication system, making full use of the spectrum, favored by more and more people. But the high PAPR makes the transmission efficiency of the system is limited. In the downlink power line communication system, transmitting the downlink signal collector, a multi-carrier technology, can greatly improve the system spectrum utilization rate and the data rate, which can make up for the high cost brought by PAPR power amplifier; In the uplink, the terminal as the sender, and the State Bureau of quality and technical supervision stipulates the power terminal power consumption standard, namely the acquisition terminal under normal power consumption should be less than 1W[1]; This requires the terminal to ensure transmit power at the same time to reduce the power consumption of the terminal as far as possible, However, high PAPR make this requirement becomes more difficult, At the same time, power requirements increase, also increase the cost and difficulty of realization of terminal equipment. In order to reduce the high PAPR value of this problem, many scholars put forward different solutions: The Article [2] put the shear and compression and expansion to reduce the PAPR value, but the distortion caused by the nonlinear signal; Document [3] proposed to reduce the PAPR value by signal encoding, but there are a lot of redundancy in the encoding process, which makes the communication rate lower; The Article [4] put the partial transmit sequences (PTS) to reduce the PAPR value, this sequence with minimal PAPR to send, it is easy to cause information loss. The reducing PAPR method based on the problems, according to LTE uplink communication technology schemes, the SC-FDMA technology is introduced to the PLC uplink.

At last, in order to show the efficiency of both SC-FDMA and OFDMA for uplink system in a power line communication system, In this paper, I simulated include: the characteristics of the PAPR, the terminal sends the same power resulting throughput, eNodeB need to achieve the same throughput required power and the same power are simulated with throughput .

Low voltage PLC communication system

Low PLC topological structure

Low voltage PLC communication network is to set up the communication network between concentrator and communication terminal, this will make the communication link between concentrator and communication terminal to maintain smooth. In the low-pressure side of the power line carrier communication, a transformer station in the region, and sometimes requires some communication terminal concentrator acts as a relay node can communicate with all communication between the terminals within the network. Topology shown in Fig 1, it is the most common single relative communication terminal network structure. The user through the PLC Modem connected to the indoor power socket[5], through the PLC connection with the building distribution transformer terminal PLC master device gateway, complete access to the last one hundred meters. Users only need to install a PLC-Modem, do not dial, receive and send Internet messages can be online.

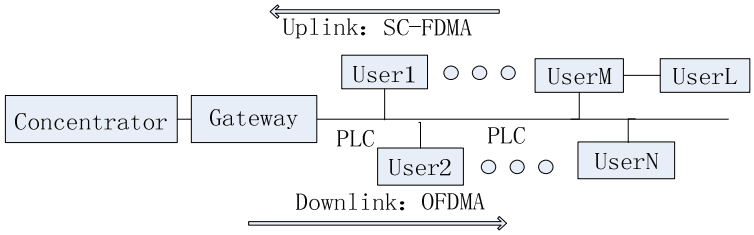

Fig 1 Connection diagram of user system

The PLC uplink and downlink communication technology

At low PLC topology, if multiple users at the same time to send the command of concentrator, the concentrator will need to provide a lot of information to the user in the circumstances allow, which requires the downlink data transmission rate of the massive. Due to the PLC communication system in the future and to satisfy users and concentrator information interaction, complete daily internet service business, it's for uplink data transmission ability put forward higher requirements. OFDMA technology scheme can realize the characteristic of orthogonal between users and the bandwidth strong extensibility, resistance to the decline, and can improve the multiuser diversity gain. But the existence of high PAPR value makes the system power utilization limited. For the downlink communication, concentrator as the transmitter, can tolerate higher cost and power amplifier. But in the uplink communication, terminal capacity is limited, especially the transmit power constraint, which makes the selectivity in the uplink transmission technology in the presence of great influence. The higher PAPR, the transmitting end to increase the ADC and DAC complexity, reduce the efficiency of RF power amplifier to meet the communication requirements, which eventually led to the transmitter power amplifier cost and power consumption increase. For the majority of end-users, this is intolerable. In LTE communication system, SC-FDMA system as the wireless uplink technology is feasible, then compared to the power line carrier technology of cable system also can be applied to technology. Therefore, this article will be to overcome the SC-FDMA technology as power line communications technology solutions downlink high PAPR problem, this program can effectively reduce the cost and power consumption of the transmitter power amplifier.

Principles reduce peak to average ratio

Peak to average ratio is defined

PAPR mainly characterize the magnitude of the peak and the average ratio between the transmitted signals. The mean PAPR calculation formula is as follows:

$$PAPR(\mathrm{dB}) = 10\log_{10}\frac{\max\limits_{0\le n\le N-1}\{|x_n|^2\}}{E\{|x_n|^2\}} \quad (0 \le n \le N-1) \tag{1}$$

In the uplink, SC-FDMA system is a frequency domain generated by the method, i.e., by the DFT-spread OFDMA system. DFT extension OFDM technology is the essence of IFFT in processing before to the discrete Fourier transform of expanding the system, the adoption of DFT processing, signal from time domain to frequency domain, and then through IFFT module from frequency domain to time domain. Since each user signal waveform is similar to single carrier, thus being regarded as single carrier technology. Because each user sends a signal waveform is similar to that of single carrier, thus being treated as a single carrier technology. The single carrier technology makes Max $\{|x_n|^2\}$ values of the formula (1) in the low formula, so that the peak to average relatively low.

In downlink link, the OFDMA signal in the OFDMA system is composed of multiple independent after addition of subcarrier signal modulation, and the synthesis of such signals is likely to have larger peak power, namely the relative formula 1 has a larger Max $\{| x_n|^2 \}$item, therefore OFDMA system has a larger average peak ratio.

Design and Simulation of the system model

Simulation design

Equipped with four users, their rate is Vp=[150, 150, 200, 200], which the top two real users, two for non real time users. In this paper, I am using MATLAB simulation both OFDMA and SC-FDMA in the system. Parameters are set as follows: Power is 10mW; the subcarrier number is 512; BER: real-time user of 10-4, non-real-time user 10-6; SNR: real-time user 5.4827, non-real-time user of 8.4213; Using equal power allocation algorithm; The DFT points to 16; choose QPSK modulation; For SC-FDMA centralized mapping, simulation performed 100 consecutive times.

Research and analysis of simulation results

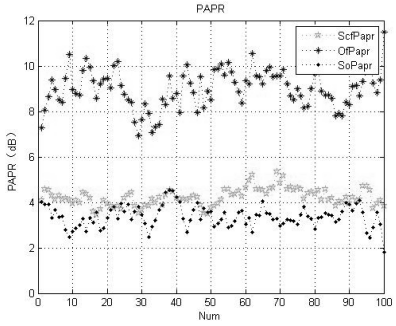

Fig 2 PAPR Compare

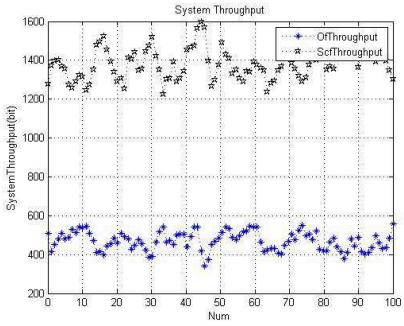

Fig 3 System Throughput Compare

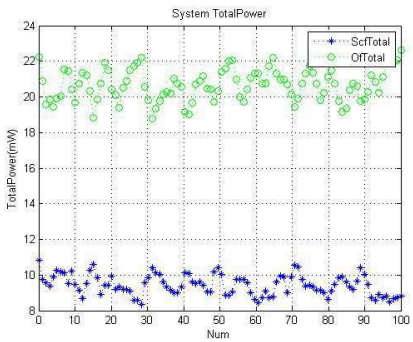

Fig 4 System Total Power Compare

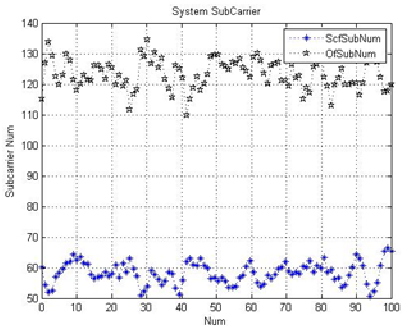

Fig 5 32 bits required subcarrier number

The OFDMA and SC-FDMA two PAPR value of the system are compared, the results as shown in Fig 2; The PAPR value of SC-FDMA is 4.2dB significantly less than the mean value of OFDMA system9dB, and compare with the baseband signal PAPR is relatively close, the value is slightly more than the value of PAPR baseband signal. Therefore, the SC-FDMA system can effectively improve the utilization rate of power communication system. Compared with SC-FDMA, the

baseband signal values of PAPR, OFDMA higher than about 4.8dB, this is mainly because the OFDMA is directly through the IDFT transform, achieve multiple sub carrier modulation, sub carrier super imposed parallel output; while the SC-FDMA is through a DFT-IDFT transformation, the two transformation, each point on the power change can be considered to be offset, this is because the transformed output as the input symbol or as a weighted superposition of input symbols, making SC-FDMA with low PAPR characteristics of single carrier unique.

The simulation with power under the system throughput

With the same power how throughput is in system as shown in Fig 3. Based on the equal power allocation algorithm, the 10mW resource is allocated to the 512 sub carrier, then according to the needs of users, the subcarrier allocation. The simulation results show that: in the premise of transmit power and subcarriers is certain, SC-FDMA per second throughput for 1400bit, while the OFDMA system per second throughput for 500bit, the total throughput of SC-FDMA system was significantly higher than that of OFDMA system throughput. Therefore, the power system using SC-FDMA was higher than that of the OFDMA system, the transmit power, the obtained throughput.

The simulation system under the same throughput of transmission power

When 100 bits as the output of the same throughput, and SC-FDMA on the power required to send the OFDMA system simulation, the simulation results shown in Fig 4. The results showed in Fig 4: 1500 bits per second to complete a certain need for SC-FDMA systems around 9.8087mW, while the OFDMA system requires about 20.1358mW; These results indicate that the same throughput requirements, SC-FDMA system requires far less than OFDMA transmission power system, further demonstrates the comparison with OFDMA systems, SC-FDMA uplink power communication system, the more efficient power utilization, low power consumption characteristics of the terminal.

The same rate under the same power required by the user subcarrier simulation

Set power source provided for the 10mW, the system in accordance with the equal power allocation algorithm to assign each user rate, the rate of each user to achieve 150bit/s, the simulation results are shown in Fig 5. It shows: the SC-FDMA system to provide users with sub carrier to about 58 to meet the needs of its rate, while the OFDMA system needs to provide sub carrier to about 128 to meet its rate to the user, the number of subcarriers for each user of the former than the latter reduces 70 subcarriers. Therefore, the SC-FDMA system compared to the OFDMA system so that the system resource utilization rate higher.

Conclusions

In this paper, the simulation of different power required for the PAPR OFDMA and SC-FDMA these two kinds of the value of the system, under the same power system with different throughput, throughput and power system with the same rate of case the user required a subcarrier number. The simulation results show that: compared with OFDMA, the SC-FDMA system has a number of sub carriers lower PAPR, under the same power, high throughput with low power and throughput under analogous rate less can meet the needs of users, the same rate etc..According to the characteristics of power line communication, further demonstrates the SC-FDMA system into the necessity and superiority of power line communication.

Keywords: stitching; phase correlation; SIFT; feature vector

Abstract: Proposed a new stitching algorithm to suit for coal mine. Cross-power spectrum phase information is used to coarse matching fast and overlapping regions can be found. Invariant features are extracted by using the dimensional reduced SIFT algorithm- sample principal component analysis. RANSAC combined with iterative L-M nonlinear optimization algorithm can improve projection matrix. New algorithm can improve the matching efficiency, and it's suit for coal mine environment.

1 Introduction

Image stitching technology is a hot research in computer vision. At present, to get the bigger perspective picture, most use the annular panoramic lens, fisheye camera and image mosaic methods [1, 2]. The annular panoramic lens and the fish eye camera will produce distortion, and has a low resolution, high cost. Image stitching takes many pictures photoed by ordinary machine according to features, you can get the big picture perspective and it has good market prospects. For coal and other low-light, high noise and blur complex environment, direct mosaic effect is not ideal, in order to adapt to the complex environment, it need an anti-light, noise, high speed, high precision stitching algorithm.

In this paper, First, using phase correlation algorithm reduced the image feature points overlapping ranges. Next, the sample principal component analysis [3] method reduced the dimensions of SIFT(Scale-invariant feature transform)[4] algorithm with 128 vector and improved the computing efficiency. Last, corresponding matching points of two images selected by SIFT combined with RANSAC (Random sample consensus) [5] and L-M (Levenberg-Marquardt) [6]to establish projection model for stitching.

2 Phase coarse matching

Phase correlation algorithm can quickly rough estimate overlap regions of image. Since the signal's characteristics in Fourier transform, using phase correlation algorithm cross power phase information can achieve image registration. This method is less dependent on the gray scale information, illumination changes well and noise robustness. Algorithm is as follows:

Let two images are $p_1(x,y)$, $p_2(x,y)$, its translational motion model is $p_1(x,y)=p_2(x-\Delta x,y-\Delta y)$, Δx, Δy are translation variables. After Fourier transform, getting $P_1(u,v), P_2(u,v)$. According to the shift characteristics:

$$P_2(u,v)=e^{-j2\pi(u\Delta x+u\Delta y)}\cdot P_1(u,v) \tag{1}$$

Image cross power spectrum is:

$$\frac{P_1^*(u,v)P_2(u,v)}{|P_1^*(u,v)P_2(u,v)|}=e^{-j2\pi(u\Delta x+u\Delta y)} \tag{2}$$

P_1^* represents a conjugate of P_1. Impulse function can be obtained after inverse Fourier transform:

$$F^{-1}[e^{-j2\pi(u\Delta x+u\Delta y)}]=\delta(x-\Delta x,y-\Delta y) \tag{3}$$

Wherein the peak size of impulse function represents a number of correlation between P_1 and P_2. Peak represents range of [0,1].

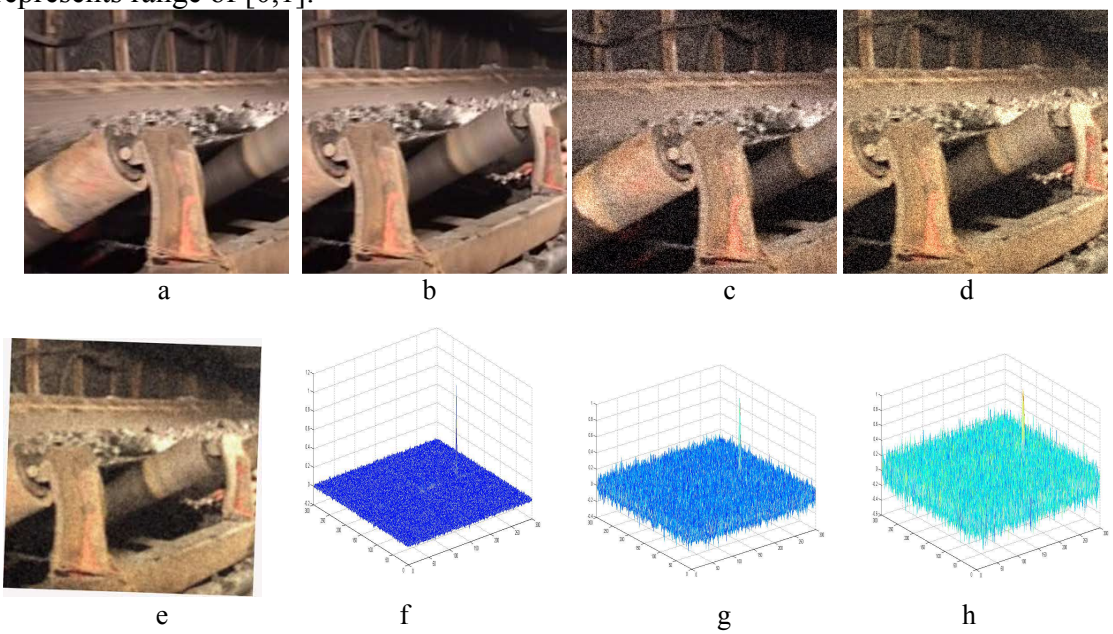

Fig.1 Phase correlation matching

In Fig.1, a and b are original images, f is the distribution of the impulse energy function after a and b normalized. The number of the overlapping area size determines the size of the peak. Image position determines the translational motion parameters. C is a plus Gaussian noise with variance 10. D is b plus noise and light meanwhile. G is impulse function energy distribution of c and d. Single peak of impulse function turns into scattered small peaks, and peak value remains stable. On the basis of d, e increased Gaussian blur, rotation effects. H is impulse function energy distribution of c and d. As can be seen, the peak is still very robust.

Phase correlation algorithm has high efficiency, but not high accuracy when estimating parameters. Therefore, as an initial registration, then we need to further take advantage of the feature points to establish accurate matching.

3 Invariant Feature Extraction

For the occlusion, blur, scale and lighting change and other issues in the environment, currently, there is no a detection operator can solve all problems.

3.1 SIFT dimension reduction

SIFT algorithm uses multi-scale transform to find the extreme points in the scale space by extracting the feature point position and direction to make eigenvector keep unchanged to accommodate various affine transformation. SIFT algorithm has 128-dimensional feature vector affecting the real-time monitoring system. This paper will combine SPCA (sample principal component analyse) and SIFT algorithm to reduce the dimensions.

N represents the number of feature points， p represents vectors for each feature point. Through following sample principal component analysis, it can reduce the dimensions for the vectors interrelated.

S1： $x_i=(x_{i1},x_{i2},...,x_{ip})^T, i=1,2,...n.$ is a sample of $X=(X_1,X_2,...,X_n)^T$， capacity is n， sample covariance matrix is expressed as:

$$\Sigma=\frac{1}{n-1}\sum_{k=1}^{n}(x_k-\bar{x})(x_k-\bar{x})^T \tag{4}$$

Where $\bar{x}=(\bar{x}_1,\bar{x}_2,...,\bar{x}_p)^T$， $x_j=\frac{1}{n}\sum_{i=1}^{n}x_{ij}, i=1,2,...p$.

S2：Eigenvalue of the covariance matrix is $\hat{\lambda}_1\geq\hat{\lambda}_2\geq...\geq\hat{\lambda}_p\geq 0$, orthogonal unit eigenvector is

$\hat{e}_1, \hat{e}_2, ..., \hat{e}_p$, $\hat{e}_i = (\hat{e}_{i1}, \hat{e}_{i2}, ..., \hat{e}_{ip})$, $\hat{e}_i \hat{e}_i^T = 1$, $i = 1, 2, ...p$. (5)

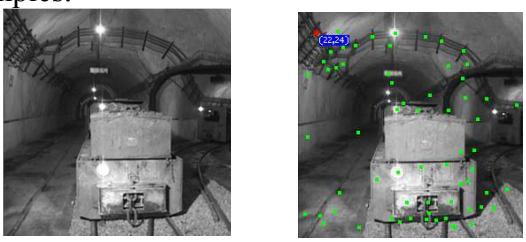
S3：The i-th sample main component is：

$$y_i = \hat{e}_{i1} x_1 + \hat{e}_{i2} x_2 + ... + \hat{e}_{ip} x_p \quad (6)$$

$i = 1, 2, ...p$, substituting observations i， $x_k = (x_{k1}, x_{k2}, ..., x_{kp})^T, k = 1, 2, ...n$, get the i-th principal component scores $y_{ki} (k = 1, 2, ...n)$ of y_i .

S4：Sample covariance of y_i and y_j is 0, where i is not equal to j， $\sum_{i=1}^{p} \hat{\lambda}_i$ is the total variance of the sample， $\hat{\lambda}_i / \sum_{i=1}^{p} \hat{\lambda}_k (i = 1, 2, ...p)$ is the i-th sample principal component contribution rate of x , $\sum_{i=1}^{m} \hat{\lambda}_i / \sum_{k=1}^{p} \hat{\lambda}_k$ is cumulative m sample principal component contribution rate.

As Fig.2 shows, experiment selected an locomotive image of 300 * 300 underground. Feature points extracted by the SIFT algorithm. Select the area surrounding the feature points with 12 * 12 to describe them. Sample characterization vectors are gray values of pixels within the region to analyze the principal component of samples.



a. Locomotive b. Feature points

Fig.2 Feature points generated

Table 1 12 * 12-dimensional feature vector principal components contribute

Principal component	Eigenvalues	Difference between Eigenvalues	Principal component contribution rate (%)	Cumulative contribution rate (%)
1	4.41439183	2.36945738	0.4013	0.4013
2	2.04493446	0.80303153	0.1859	0.5872
3	1.24190293	0.29798645	0.1129	0.7001
4	0.94391647	0.22911305	0.0858	0.7859
5	0.71480343	0.29822424	0.065	0.8509
6	0.41657919	0.01050982	0.0379	0.8888
7	0.40606937	0.10042222	0.0369	0.9257
8	0.30564715	0.06445848	0.0278	0.9535

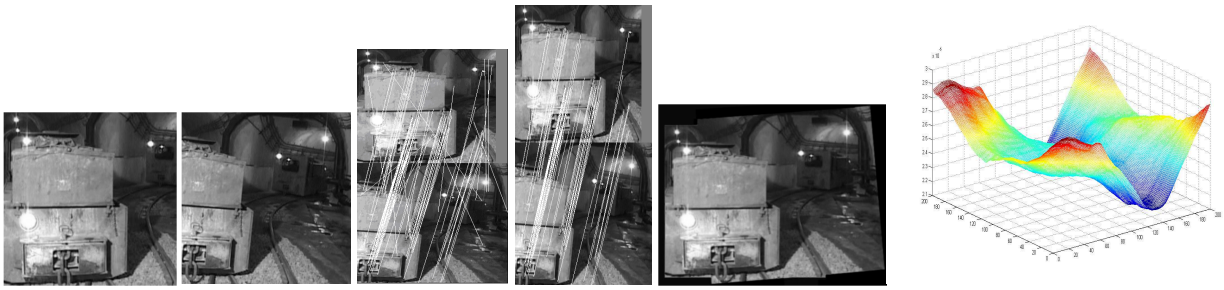
Fig.2 contains feature points generated by locomotive. As can be seen from Table 1, even though dimensions of feature vectors up to 144, but most information of feature vectors can be described by the above eight principal components. So it's no less to use the unrelated first few principal components to describe original image.

3.2 Accurate extraction and matching

To further eliminate error matched pairs and use exact matched pairs to establish image transformation matrix, the paper combined RANSAC algorithm of the angle, the length filter for exact match. Select the initial matching features, using the internal points which errors are less than the threshold point. Repeat random sampling within a set of internal points, when the number of the two set of points nearly identical, recalculate the estimate the model parameters. Using L-M algorithm to iterative and minimize the error function, then get the exact match pairs.

As Fig.3 below, a, b are original images of locomotive, the number of initial SIFT matching points are 128. Through the image transformation relations between a and b , transformation matrix H is obtained.

$$H = \begin{bmatrix} 0.9889 & 0.4865 & 30.9451 \\ 0.4167 & 0.9975 & 5.6196 \\ 0.0001 & 0.0001 & 1 \end{bmatrix}$$



a b c d e f

Fig.3 Stitching trellis

Seen from the transformation matrix H, comparing to the first image, the size of the second image has a slight change, and exist the situation of displacement and rotation. Exact match contrast as shown in Fig.3.

Table 3 Match results

Dimension	Stitching Time	Match Points	Correctly matching points	Matching rate
9	0.83s	64	61	95.31%

In Fig.3, c, d are the initial and exact matching results. Can be seen, many error points removed by exact match. E is the stitching result of using sample principal component 9-dimensional exact match, f is the mesh representation. Because 9-dimensional feature vector rarely occupy storage space, matching efficiency has been greatly improved. Fig.3 shows that while enhancing systems real-time performance, it does not affect the matching accuracy.

4 Conclusion

Proposed a new stitching algorithm for the widespread existence of low resolution, blur, large noise, lighting changes characteristics in complex underground environment. Cross-power spectrum phase information is used to coarse matching fast and overlapping regions can be found. Invariant features are extracted by using the dimensional reduced SIFT algorithm- sample principal component analysis. RANSAC combined with iterative L-M nonlinear optimization algorithm can improve projection matrix. Experiments show that the new algorithm has a robust characteristic and stitch accurately and smoothly, it is better to grasp the overall message.

Abstract. Experimental phonetics development to today has undergone a long and complicated process. The field of study from the acoustic analysis of expansion to the physiological and perceptual field. Speech aerodynamics signal is one of the most important physiological signal language research, plays an important role in human phonation process. Air pressure signal as an important physiological signal, which has great significance to the study of speech physiology, mainly through speech aerodynamics equipment acquisition. In this paper, according to the need of research, established by MATLAB program analysis platform, can be edited on the speech, the airflow and pressure signal is better, which is more suitable for speech research.

Introduction

Experimental phonetics through long-term development has undergone a long and complicated process, from previous research in the field of acoustic parameters and characteristics are analyzed to study the physiological and perceptual voice multi-modal and gradually extended to the field of multi-modal speech research as the main content. By using various experimental instruments, acquisition and analysis of physiological signals to various speech. Study of speech from speaking to listen to the entire mechanism and principle, and properties of physiological, physical and psychological aspects of speech signals. And how to use these attributes to explain linguistic problems is the main objective of speech and voice multimodal study[1].

With the development of science and technology, voice multimodal research methods are constantly updated, more and more instruments are introduced into this area, from the early laryngoscopy, oscilloscopes, acoustic spectroscopy and X-ray, and now Airflow equipment (PAS6600), Electropalatography (EPG), Electronic glottis instrument (EGG), electromyography (EMG), electroencephalogram (EEG), respiration, nuclear magnetic resonance (MRI), etc. [2]. These various physiological signal acquisition instrument air pressures as the air flow signal, the voice signal and the EPG signal, also reveal more speech production mechanism is extremely characteristic. In the speech production process flow plays a vital role in generating speech without the participation of lung airflow, and airflow from the lungs, is bound to generate pressure. With the development of experimental phonetics, air flow and air-pressure parameters is also used in acoustics, speech recognition, speech synthesis, voice typology and other aspects of the progress to provide a great help[3].

At present, air pressure collection equipment produced for the U.S. KAY audible speech aerodynamics system, the signal analysis and processing are the main device supporting a series of software. Physiological research is mainly used for the series of software, but cannot meet the current needs of phonetics. And the software of KAY company to save the file as a NSP file, the existing speech analysis software cannot operate on the file format. Therefore, for the development of a set of speech multimodal analysis of airflow and pressure signal platform is necessary. This paper analyzes the NSP files and WAV file formats, combining voice multi-modal studies are needed to achieve NSP file and convert WAV files. Also can be used for signal processing method of analysis and research

the airflow and pressure signal, for the future research and provide the technical foundation for the development of analysis platform [4].

The Nsp Signal Acquisition and Analysis

2.1 Acquisition Equipment

The phonetic study widely adopted by America KAY company production of the sounds of speech air dynamic system (Phonatory Aerodynamic System 6600). The system external hardware module comprises a handheld device with both hands handle (handheld by speakers in the process of data collection), airflow mask, pressure sensor, test tube and a microphone to ergonomic criteria together. The signal conditioning, filtering and data sampling are in line with the strict standards of sound and aerodynamic data acquisition [5].

Before the signal acquisition, signal conditioning and data sampling equipment, in strict accordance with the standards of debugging, to calibrate microphone fixed position. In the acquisition process in order to ensure the accuracy of the pressure signal, entrance pipe is arranged in the pronunciation of population, and keep the mask and facial mask tightly to ensure no leakage, and then the signal acquisition after simple pronunciation training.

2.2 The NSP format file

Because there are few readily available information on the NSP file format specific introduction, we adopted UltraEdit software to open files to search matching to determine the file header and the data part. Figure 1 is the code above the input signal, shown below is the code without input signal. By contrasting the code file, the code of two signal file, the first eight lines of roughly the same. The ninth line began to have input file assumes the regular data are airflow and pressure signal. Without input signal data file because it is no empty file, then the code is 0. To exclude the impact time and file size and other parameters, we can draw the conclusion: airflow pressure signal NSP file header for the first eight rows. That is the first eight rows of data is the NSP file header information, ninth row start to finish for the signal data of NSP file.

Figure 1. The NSP file format data

By comparing empty files and files containing the signal, we found that the first eight rows of data to a file paramount additional information, data files are stored is to start from the ninth row. We conclude that the data is divided into three parts, the front part of speech signal, the middle part of the airflow signal data, the last part is the air-pressure signal data. The three part data according to the time points are arranged, and each accounted for one-third of one. We use fread (fid, 'int16') function of MATLAB, the NSP files in hexadecimal readout on three columns of a matrix in which multiple rows. Among them, each row of the matrix corresponds to a point in time sampling frequency. The row of the matrix corresponds to the data in each part, wherein the first column data for speech, second column for airflow, third column for air-pressure. In the later need the data used, remove the corresponding columns from the matrix.

The NSP format into WAV format

3.1 The WAV format

WAV file as the acoustic format multimedia use, it is based on RIFF format as a standard. RIFF Resource Interchange File Format is the English abbreviation of the first four bytes of each WAV file is "RIFF". WAV file consists of two parts, the header and body composition data. Where the file header is divided into RIFF or WAV files and audio data segment identifier format segment two parts. WAV file content and format of each part as shown in Table1.

Table 1 The file header of WAV file

Offset address	Byte	Data type	Content
00H~03H	4	char	"RIFF" symbol
04H~07H	4	long int	The length of the file
08H~0BH	4	char	"WAVE" symbol
0CH~0FH	4	char	"fmt" symbol
10H~13H	4		Transition byte (indefinite)
14H~15H	2	int	Format categories (10H said sound data in form of PCM)
16H~17H	2	int	The number of channels
18H~1BH	2	int	The sampling rate (the number of samples per second), said the playback speed of each channel
1CH~1FH	4	long int	Waveform audio data transfer rate
20H~21H	2	int	Adjust the data block number (in terms of bytes)
22H~23H	2		All samples of each channel of the data bits
24H~27H	4	char	Data tag " data "
28H~2BH	4	long int	The sound data length

3.2 The NSP saved as WAV format

The entire program flow as shown below:

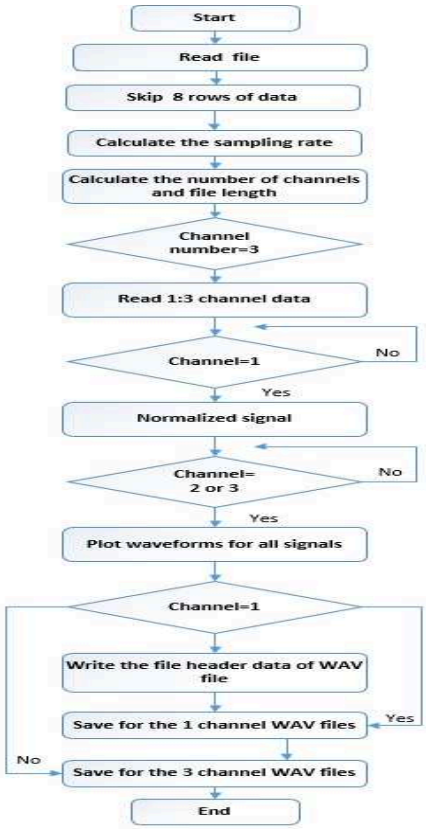

Figure 2. The analysis platform frame diagram

In order to facilitate the analysis separately for each channel signal, we make analysis platform in the MATLAB environment, combining the speech signal, airflow and air-pressure signal. By reading

the signal, NSP format will be saved as WAV format, for each channel data analysis. The platform should first read in Nsp format, and then through the GUI programming display waveform. In the waveform display, according to the signals required for data storage, unified format for the WAV.

First, read the NSP format files, remove header files first eight rows of data, the effective use of the data file fread (fid, 'int16') function, the NSP document read in hexadecimal. Then calculate the sample rate, number of channels, and file size. Then the normalized, normalized to the signal, only the first channel speech signal, the airflow and air-pressure signal is not normalized. Then the separation channel according to the needs of the study. If you only study the speech signal, then save the data of the first channel. If study the airflow and air-pressure signal, then save the data of all channel. Data storage formats are WAV files, is helpful to the study of late by the speech software.

When you save the format, first in the GUI display waveform, according to the quality of the signal at the different channels to be saved. If only the analysis of speech signal, save only the signal of the first channel. The program will automatically determine, if not only one channel, save the signals of all channels. Signal data are stored in WAV files, to facilitate the later analysis and research.

Conclusions

The platform can be realized on the NSP format file data of custom analysis, more conducive to the analysis of each channel signal data. Platform menu includes five main menus: File, Edit, View, Play, and Help. The menu File, including 7 sub menus are open NSP file, save the file as WAV, open the saved wav file, save file as, channel separation, save selected file, exit. Edit menu includes cut, trim reverse. In the View menu, including view all, view selected, zoom in, and zoom out. Play menu includes play all, play selected. The last one is MATLAB Help file. In the process of work later, will be further on the platform for perfection, while the realization of the basic functions, to achieve the parameters of the signal analysis and processing.

Keywords: Ensemble empirical mode decomposition (EEMD), Intrinsic mode function (IMF), Frequency spectral features, Mutual information (MI), Kernel partial least squares (KPLS)

Abstract. Heavy mechanical devices of complex industrial process produce soundly mechanical vibration and acoustical signals. Some difficult-to-measure key process parameters have direct relationship with these signals. A newly ensemble empirical mode decomposition (EEMD), Fast Fourier Transform (FFT), Mutual information (MI), and Kernel partial least squares (KPLS) based modeling approach is proposed to measure these process parameters. At first, different scale intrinsic mode functions (IMFs) of mechanical vibration and acoustical signals are obtained using EEMD technology. Then, FFT transforms these multi-scale IMFs into frequency domain, and MI based feature selection method selects interesting frequency spectral features. Finally, KPLS constructs the final soft sensor models using the selected features. Experimental results based on vibration and acoustical signals of ball mill demonstrate this approach is more effective than other exist multi-scale decomposition based methods.

Introduction

There are lots of heavy mechanical devices in complex industrial process such as mineral grinding process. These devices are always key important equipments of the whole product process. However, some important process parameters inside these devices cannot be accurate detected directly or in first principal. Thus, it is very difficult to realize the operational optimization control of such complex industrial process [1]. Normally, these devices produce soundly mechanical vibration and acoustical signals. Studies show that frequency spectra of these signals contain information relative to these difficult-to-measure key process parameters. For examples, frequency spectra of shell vibration and acoustical signals of ball mill in grinding process contain useful information for measuring load parameters (mineral to ball volume ratio (MBVR), pulp density (PD) and charge volume ratio (CVR)) inside the ball mill [2]. Many single-scale frequency spectrum based soft sensor models have been constructed using shell vibration and acoustical signals [3,4]. However, these models are difficult to understand and interpretation.

Studies show grinding mechanism inside ball mill is very difficult to explain. Moreover, shell vibration signal of ball mill is caused by different impact forces with different amplitudes and frequencies. Therefore, the shell vibration signal consists of different sub-signals. Moreover, shell vibration is the source of acoustical signal. Thus, how to decompose these multi-scale signals to different sub-signals with different physical meaning has become a new focus recently. Empirical mode decomposition (EMD) technology is one effective adaptively decompose method based on partial characteristic of the signal [5], which was first used in our former studies [6,7,8]. However, no satisfied modeling performance was obtained. What is the reason?

Reliable frequency spectrum is foundation to construct an effective mechanical vibration and acoustical signals based process parameter soft sensor model. Recently, many shortcomings of EMD

technology has been found, such as lacking a theoretical foundation, end effects, sifting stop criterion, extremum interpolation etc. One of the outstanding disadvantages is mode-mixing phenomenon. However, the newly proposed ensemble EMD (EEMD) can overcome the mode-mixing problem [9], which calculates the mean of an ensemble of decompositions that have different instances of noise added to the signal. Aims at the high dimensional problem of frequency spectrum, mutual information (MI) based feature extraction method are used widely. The MI is more comprehensive than the other normal feature selection method [10], which has been used in gene selection [11].

Therefore, a newly EEMD, Fast Fourier Transform (FFT), MI and Kernel partial least squares (KPLS) based modeling approach is proposed to measure these difficulty-to-measure key process parameters. At first, the original mechanical vibration and acoustical signals are decomposed into IMFs with different time scales. Then, these multi-scale IMFs are transformed into multi-scale frequency spectra. And these valued frequency spectral features relative to different key process parameters are selected based on MI based feature selection method. Finally, these selected features are serial combined and fed into KPLS based soft sensor models. The experimental results shows this approach is effective compared with the other exist multi-scale decomposition based methods.

Strategy of Intrinsic Mode Functions Features based Modeling approach

Based on the former analysis, a new intrinsic mode functions frequency spectral features based modeling approach is proposed. This approach consists of multi-scale mechanical vibration and acoustical signals decomposition module, multi-scale frequency spectrum transform module, frequency spectral features extraction module and difficulty-to-measure key process parameters modeling module, whose structural is shown as Fig. 1.

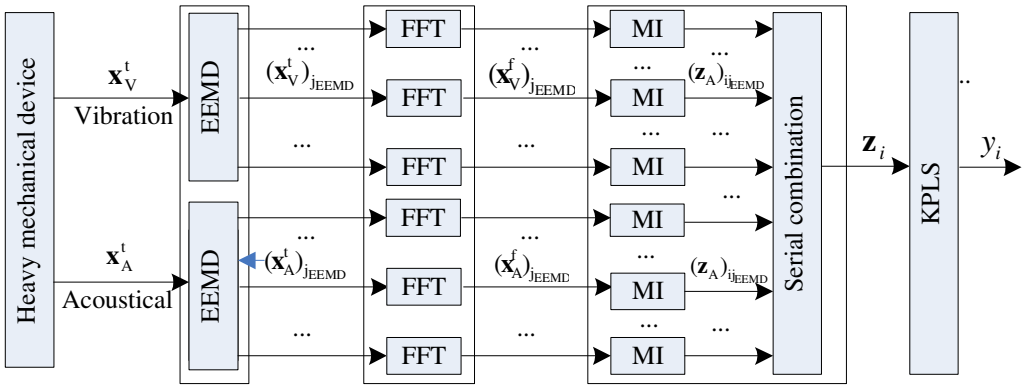

Fig.1 Strategy of intrinsic mode functions features based modeling approach

In Fig. 1, the superscript t and f represent time and frequency-domain signals; the subscript V and A represent mechenical vibration and acoustical signals; $\mathbf{x}_V^t$ and $\mathbf{x}_A^t$ are the original time-domain signals; $(\mathbf{x}_V^t)_{jEEMD}$ and $(\mathbf{x}_A^t)_{jEEMD}$ represent the j_{EEMD}th IMF sub-signals; $(\mathbf{x}_V^f)_{jEEMD}$ and $(\mathbf{x}_A^f)_{jEEMD}$ represent the j_{EEMD}th IMF frequency spectrum; $(\mathbf{z}_A)_{ijEEMD}$ and $(\mathbf{z}_A)_{ijEEMD}$ represent the j_{EEMD}th selected IMF frequency spectral features from $(\mathbf{x}_V^f)_{jEEMD}$ and $(\mathbf{x}_A^f)_{jEEMD}$ for the ith process parameters; $\mathbf{z}_i$ represent the combined frequency spectral features for the ith process parameters.

Multi-scale vibration and acoustical signals decomposition module: Based on EEMD technolegy, the original mechanical vibration and acoustical signals are decomposed into IMFs with different time scale. The relationships among them can be represented as:

$$\mathbf{x}_V^t = \sum_{j_V=1}^{J_{VEEMD}} (\mathbf{x}_V^t)_{jEEMD} + (r_{J_V})_{EEMD} \tag{1}$$

$$\mathbf{x}_A^t = \sum_{j_A=1}^{J_{AEEMD}} (\mathbf{x}_A^t)_{jEEMD} + (r_{J_A})_{EEMD} \tag{2}$$

where, $(r_{J_V})_{EEMD}$ and $(r_{J_A})_{EEMD}$ represent residual signals; J_{VEEMD} and J_{AEEMD} represent the number of vibration and acoustical IMFs respectively.

Multi-scale frequency spectrum transform module: Based on FFT, different time domain IMFs are transformed into frequency spectrum. Take the j_{EEMD}th IMF as example, this process can be reprented:

$$(\mathbf{x}_{\mathrm{V}}^{\mathrm{t}})_{\mathrm{jEEMD}} \xrightarrow{\mathrm{FFT}} (\mathbf{x}_{\mathrm{V}}^{\mathrm{f}})_{\mathrm{jEEMD}} \tag{3}$$

$$(\mathbf{x}_{\mathrm{A}}^{\mathrm{t}})_{\mathrm{jEEMD}} \xrightarrow{\mathrm{FFT}} (\mathbf{x}_{\mathrm{A}}^{\mathrm{f}})_{\mathrm{jEEMD}} \tag{4}$$

Frequency spectral features extraction module: Based on MI feature selection algorithm, MI values of different IMFs freqeuncy spectral features are calculated. These features with MI values higher than a threshold value are selected. Take the j_{EEMD}th IMF as example, this frequency spectrum feature selection process can be reprented as:

$$(\mathbf{x}_{\mathrm{V}}^{\mathrm{f}})_{\mathrm{jEEMD}} \xrightarrow{\mathrm{MI}\left((\mathbf{x}_{\mathrm{V}}^{\mathrm{f}})_{\mathrm{jEEMD}}\right)_{ip} > \theta_{threshold}} (\mathbf{z}_{\mathrm{V}})_{\mathrm{ij_{EEMD}}} \tag{5}$$

$$(\mathbf{x}_{\mathrm{A}}^{\mathrm{f}})_{\mathrm{jEEMD}} \xrightarrow{\mathrm{MI}\left((\mathbf{x}_{\mathrm{A}}^{\mathrm{f}})_{\mathrm{jEEMD}}\right)_{ip} > \theta_{threshold}} (\mathbf{z}_{\mathrm{A}})_{\mathrm{ij_{EEMD}}} \tag{6}$$

where, $\mathrm{MI}\left((\mathbf{x}_{\mathrm{V}}^{\mathrm{f}})_{\mathrm{jEEMD}}\right)_{ip}$ represent MI value of the pth frequency spectral features for the ith key process parameters; $\theta_{threshold}$ represent threshold value. All the selected features using MI method for the ith process parameters can be represented as:

$$\mathbf{z}_i = [(\mathbf{z}_{\mathrm{V}})_{i1_{\mathrm{EEMD}}},\ldots,(\mathbf{z}_{\mathrm{V}})_{ij_{\mathrm{EEMD}}},\ldots,(\mathbf{z}_{\mathrm{V}})_{iJ_{V\,\mathrm{EEMD}}},(\mathbf{z}_{\mathrm{A}})_{i1_{\mathrm{EEMD}}},\ldots,(\mathbf{z}_{\mathrm{A}})_{ij_{\mathrm{EEMD}}},\ldots,(\mathbf{z}_{\mathrm{A}})_{iJ_{A\mathrm{EEMD}}}] \tag{7}$$

Difficulty-to-measure key process parameters modeling module: Based on KPLS algorithm, construct soft sensor model for the ith process parameters using features $\mathbf{z}_i$.

Results and discussion

Mechanical vibration and acoustical signals of a laboratory scale ball mill (XMQL-420×450) of grinding process are picked up by accelerometer located on the mill shell and microphone near the abrasion zone of wet ball mill. Load parameters inside the mill (MBVR, PD and CVR) are modeling using the proposed modeling approach. EEMD with ensemble number 10 and white noise amplitude 0.1 is used to decompose shell vibration and acoustical signals into IMF sub-signals. The Same FFT parameters as literature [2] are used to obtain IMF frequency spectra. Maximum and minimum MI values between IMF frequency spectral features and mill load parameters are shown in Fig. 2.

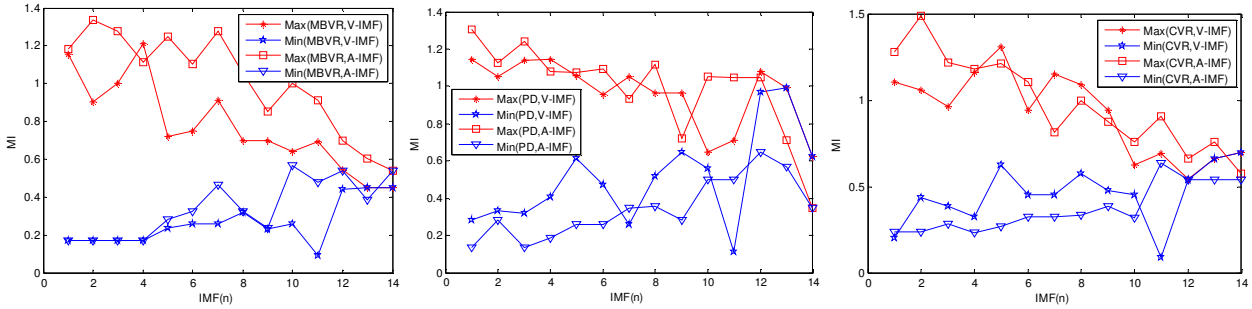

Fig. 2 Maximum and minimum MI values between IMF features and process parameters

Fig. 2 shows that the mapping relationships between IMF frequency spectral features and mill load parameters are different. According the maximum and minimum MI values, threshold values for MBVR, PD and CVR are selected as 0.4, 0.6 and 0.5 respectively. Numbers of the selected vibration and acoustical frequency spectral features for different mill load parameters are shown in Fig.3.

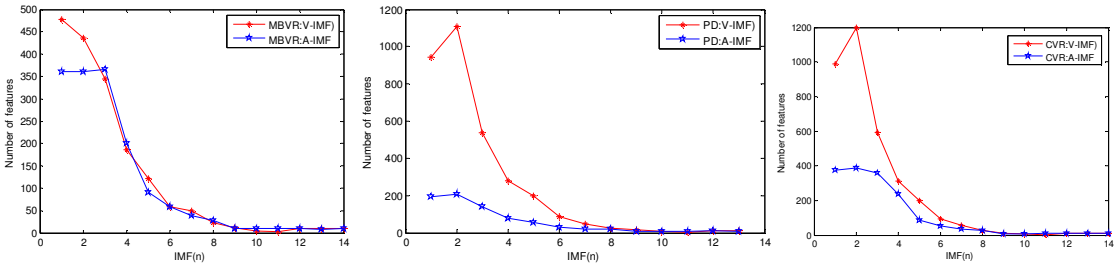

Fig. 3 Numbers of the selected vibration and acoustical features for different process parameters

Fig. 3 shows that feature numbers of MBVR is lower than that of PD and CVR. Using same RBF kernel, with kernel radius 0.4, 50 and 0.5 for MBVR, PD and CVR to construct KPLS based mill load parameters soft sensor models. Prediction results are shown in Fig. 4.

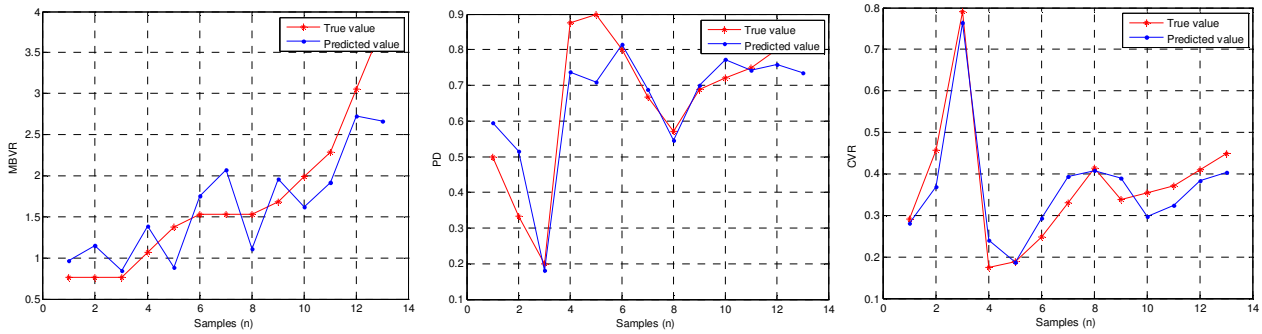

Fig. 4 Prediction curves of different mill load parameters

Fig.4 shows that MBVR model has the biggest prediction errors among three mill load parameters. The root mean square relative errors (RMSSEs) of MBVR, PD and CVR models are 0.2723, 0.1834 and 0.1610 respectively, which is lower than that of the former EMD based modeling methods. All these results show the proposed method is effective to modeling load parameters of ball mill.

Summary

This paper presents a novel modeling approach for difficult-to-measure key process parameters based on mechanical vibration and acoustical signals. Ensemble empirical mode decomposition, fast Fourier transform and mutual information technologies are used to select multi-scale frequency spectral features of these signals for different key process parameters. The selected features are fed into kernel partial least squares algorithm to construct final soft sensor model. Experimental results based on shell vibration and acoustical singles of ball mill show the proposed method has better prediction performance than former multi-scale based methods.

Key words: self-Adapt distance measure; identification information; manifold learning

Abstract. Self-adapt distance measure supervised locally linear embedding solves the problem that Euclidean distance measure can not apart from samples in content-based image retrieval. This method uses discriminative distance measure to construct k-NN and effectively keeps its topological structure in high dimension space, meanwhile it broadens interval of samples and strengthens the ability of classifying. Experiment results show the ADM-SLLE date-reducing-dimension method speeds up the image retrieval and acquires high accurate rate in retrieval.

1. Introduction

Manifold learning has risen in recent years specializing in nonlinear distribution data dimension reduction method, mainly includes isometric feature mapping (Isomer)[1] and the local linear embedded (LLE)[2] method. Compared with linear dimension reduction method, manifold learning dimension reduction method has many advantages. This paper in the local linear embedded (LLE) method, and on the basis of using the information has identified distance measure to replace the Euclidean distance measure, will identify information into the LLE algorithm. Which proposed learning methods of self-Adapt distance measure supervised locally linear embedding.

2. The algorithm of Self-Adapt distance measure

Support vector machine (SVM) is the most practical statistical learning theory, for its part, the core idea of it is to use the minimization principle into the classification of the structural risk minimization principle [3] into the classification. Its essence is to find out the training sample structure optimization classification hyperplane support vector. In mathematics sums up for a solution with inequality constraints of secondary rules. The plane can explicitly to write for:

$$w = \sum_{i \in SV} a_i y_i \Phi(x_i) \quad . \tag{1}$$

Among them, the $\Phi(x_i)$ is nonlinear from R^D to R^d projection, the a_i is Lagrange coefficient, The SV is support vector.

Assume that constraint Θ and characteristics of corresponding axis $\Theta \in \{e_1, e_2, \cdots, e_D\}$. Among them, the k feature for corresponding unit vector is e_k.The $|w \cdot \Theta|$ is Provide the kind of information to identify the characteristics of the measure of correlation. As $r_k = |w \cdot \Theta|$ in the nearest scale and the weight of each Θ d related weight. The big value of $|w \cdot \Theta|$ will make the nearest shape Θ along the contraction, And the little value of $|w \cdot \Theta|$ will stretch the nearest area along Θ the direction.

Our purpose is to use w the calculated point $r_k(x)$. Below type:

$$r_k(x) = |w \cdot \Theta| \quad . \tag{2}$$

The most attractive performance is w to capture the correlation between r_k the information, and the correlation to the index weight through the following methods of obtaining:

$$w_k(x) = \frac{\exp(Tr_k(x))}{\sum_{k=1}^{D} \exp(Tr_k(x))} . \tag{3}$$

Among them, T is a parameter, can choose the maximum r_k effect through. At the time of $T = 0$ and $w_k = 1/n$, thus ignore any difference between r_k. When T in a big change of r_k, w_k is exponentially influence. The weighted index is very sensitive to local features correlation changes, and can therefore better improve performance [4]. In addition, the index weight more stable, because it can prevent neighborhood in any direction enlarged unlimitedly.

Therefore, we hope parameters of T in the index weighted (3) with border the decrease of the distance with q increased. Using support vector in the border near the surface of the knowledge, we can through the calculation inquires the of nearest point with support vector distance estimating it is apart from the boundary of the distance.

$$B_q = \min_{s_i} \|q - s_i\| . \tag{4}$$

In this, the minimize is alternative no constraints ($0 < a_i < C$) support vector s_i. In the border around the spatial resolution by expanding support vector neighborhood of local volume unit and increase [5]. So, we can use the type to achieve our objective:

$$T = H - B_q . \tag{5}$$

In this, H is a parameter, equal to the training x and the boundary of the approximate average point distance.

$$H = \frac{1}{l} \sum_{x} \min_{s_i} \|x - s_i\| . \tag{6}$$

To do so, according to the value of the border to the relative position very well to adapt to each inquires the point. By the analysis on, adaptive local distance can use type says:

$$D(x_i, x_j) = \sqrt{\sum_{k=1}^{D} w_k (x_{ik} - x_{jk})^2} . \tag{7}$$

From this distance measure, can compute the neighbors k, and can be structure matrix of W.

3. Self-Adapt distance measure supervised locally linear embedding

For the purpose of dimension reduction is not only to the known sample points of dimension reduction, more important is to be able to find the unknown sample points inner manifold, and made the sample points to the classification of the interface distance increases as far as possible to improve generalization performance. Therefore, the use of the information has identified distance measure to replace the Euclidean distance measure construction-neighbors, put forward the measure of adaptive distance supervised learning method LLE manifold. Algorithms are described below:

Input: High dimensional data $X = (x_1, x_2, \cdots, x_n)$, $x_i \in R^D$, And every sample belong to the category of the Numbers.

Output: Low dimensional data $Y = \{y_1, y_2, \cdots y_n\}$, $y_i \in R^d$, ($d \ll D$).

4. FADM-SLLE feedback self-Adapt distance measure supervised locally linear embedding

The specific steps of Algorithm of FADM-SLLE [6] as follows:

Step1: Use LLE algorithm dimension reduction, by Euclidean distance measure similarity search method. In the initial in retrieval choose n image to give users, the user mark and retrieval of the relevant target image, get used to the feedback is an right example set I_p^0 and a error example set I_p^0. Update set I_p and I_n: $I_p = I_p \bigcup I_p^0$, $I_n = I_n \bigcup I_n^0$.And when the initial $I_p = 0$ and $I_n = 0$.

Step2: The I_p and I_n Will known as label information image point of (x_i, y_i), $x_i \in I_p \bigcup I_n$, $y_i = \begin{cases} +1, x_i \in I_p \\ -1, x_i \in I_n \end{cases}$.By SVM calculated surface classification $w = \sum_{i \in SV} a_i y_i \Phi(x_i)$.

Step3: Calculation adaptive local distance $D(x_i, x_j)$, $D(x_i, x_j) = \sqrt{\sum_{k=1}^{D} w_k (x_{ik} - x_{jk})^2}$.

From this distance measurement, high dimensional space to each of the sample points of x_i, the calculation of k neighbors, and then to build W.

Step4: The user on the feedback image to for labeling. Get used to the feedback is an right example set I_p^1 and error example set I_n^1. With this then to set I_p and I_n updated. $I_p = I_p \bigcup I_p^1$.

5. The experiment and application analysis

This paper put forward to evaluate theperformance of the algorithm is used for image retrieval, design the following experiment. The database of core image database, the selection of the 1000 images, divided into 10 categories, each containing 100 pictures. As shown in table 1 400 d image low-level features as an original features vector.

Table1. Used image feature in the experiments

Characteristic name	Dimension
Color histogram [12]	256
Color moment [13]	9
Edge histogram [12]	5
contourlet [14]	62
orientation histograms [15]	68
total	400

To remove dimension effects, in data analysis of data before pretreatment is indispensable. Were statistically speaking, regularization transform can make the poor of spacing increases, in reducing of distance, which is beneficial to the object classification expression. Therefore, this paper using this method features of pretreatment. Specific as follows:

$$x_{ij}^* = \frac{x_{ij} - \min\limits_{1 \le i \le n} x_{ij}}{R_j} \quad (8)$$

Using the SVM feedback method (FSVM) [6] and the related feedback algorithm FADM-SLLE proposed in this paper for image retrieval, SVM by gauss RBF kernel function, its parameter $\sigma = 3$, all 10 kinds of image respectively, the four feedback average precisions based on the top 25 images and 36 images are compared. the results is shown in figure 1.

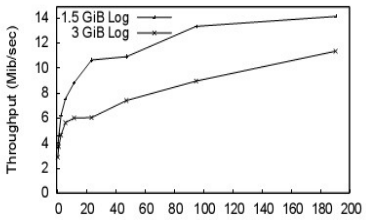

Fig. 1 Comparison result of F.25 and F.36

Graph starting point for no feedback in the original information retrieval results, as can be seen, the user for the first two rounds related feedback, the retrieval accuracy has the large scale enhancement, since then, the search precision ascension will gradually smooth. The proposed algorithm in overall scope are better than the SVM method, the two methods are significantly better than no feedback algorithm, it shows the users with feedback information related to improve retrieval performance is very good, with more feedback to explore a more relevant images, and improve the precision, the experimental results proved it.

Fig. 3 Image produced by retrieval

Figure2 in terrain for image database of the arbitrary a original image, and figure 3 after ADM-SLLE method for image retrieval to create. The experiment results show ADM-SLLE method can more accurately according to the characteristics of the source image content retrieval to the outline of the source images.

6. Conclusions

How to use a lot of no label image point to improve learning performance has become a concerned problem about the image retrieval study. This paper is about a combination of the two - the strong generalization ability of the SVM and the LLE dimension-reduction methods, putting forward a new method of supervising and man folding learning algorithm, which can classify the interval between the two to maximize the local information and keep the data. The experimental results show that the method can improve the accuracy of image retrieval.

Keywords: Extreme Learning Machine (ELM), Auto-Associative Neural Network (AANN), Deep Structure of ELM (DS-ELM)

Abstract. Extreme learning machine (ELM), a relatively novel machine learning algorithm for single hidden layer feed-forward neural networks (SLFNs), has been shown competitive performance in simple structure and superior training speed. To improve the effectiveness of ELM for dealing with noisy datasets, a deep structure of ELM, short for DS-ELM, is proposed in this paper. DS-ELM contains three level networks (actually contains three nets): the first level network is trained by auto-associative neural network (AANN) aim to filter out noise as well as reduce dimension when necessary; the second level network is another AANN net aim to fix the input weights and bias of ELM; and the last level network is ELM. Experiments on four noisy datasets are carried out to examine the new proposed DS-ELM algorithm. And the results show that DS-ELM has higher performance than ELM when dealing with noisy data.

Introduction

Extreme learning machine (ELM) is a new algorithm proposed by Professor Huang in 2004 [1], which is a simple and efficient single-hidden layer feed-forward neural networks (SLFNs). In learning process of ELM, the input weights and hidden biases are randomly chosen and not need to be tuned, while the output weights are analytically determined by the Moore-Penrose generalized inverse. ELM algorithm can not only learn much faster with a higher generalization performance than those traditional gradient-based learning algorithms, but also avoid many problems such as stopping criteria, learning rates, learning epochs, local minima that are difficult to cope with by classical gradient-based learning methods. Over the next several years, the team led by Professor Huang has done many further development based on original ELM [2-4].

While there are so many competitive advantages for the ELM technology in comparison with other traditional neural network algorithms to lure people to explore it, many shortcomings are also supposed to be awarded: (1) ELM technology ignores the noise of data that can be found almost everywhere in the real world, which may be lead to instability of the system; (2) ELM algorithm sometimes makes the hidden layer output matrix not full column due to the random choice of input weights and biases which lowers the reliability of ELM. In this paper, a new algorithm named deep structure of extreme learning machine (DS-ELM) is proposed to deal with the noise data problems.

DS-ELM consists of two level networks: the first level network is trained by auto-associative neural network (AANN) aim to filter out noise as well as reduce dimension when necessary; the second level network is another AANN net to fix the input weights and bias of ELM; and the last network is ELM but input weights and bias are kept unchanged by the second AANN net to improve the effectiveness of the whole net. The outputs of the first level network are regarded as new input data for ELM. The difference between DS-ELM algorithm and ELM lies in removing noise of datasets and fixing input weights.

Methodology

In this part, we give a detailed introduction about the structure and main processes of ELM and DS-ELM algorithm.

A. Extreme Learning Machine (ELM)

Extreme learning machine (ELM) is a single hidden layer feed-forward neural network algorithm, which contains three layers: input layer, hidden layer and output layer. The following is a further detailed explanation of ELM algorithm.

For N arbitrary distinct samples (x_i, t_i), where $x_i = R^n$ and $t_i \in R^m$, standard SLFNs with k nodes and activation function $g(x)$ are mathematically described as

$$\sum_{i=1}^{k} \beta_i \, g_i(\omega_i \cdot x_j + b_i) = y_j, \; j = 1,2, \ldots, N \quad (1)$$

Where ω_i is the weight vector connecting the ith hidden neuron and the input neurons, β_i is the weight vector connecting the ith hidden neuron and the output neurons, then, b_i is the threshold of the ith hidden neuron. If the SLFNs can approximate these N samples with zero error, that is, $\sum_{i=1}^{n} \|y_i - t_i\| = 0$. And the equation can be expressed as:

$$H\beta = T \quad (2)$$

Where

$$H = \begin{bmatrix} g(\omega_1 \cdot x_1 + b_1) & \cdots & g(\omega_k \cdot x_1 + b_k) \\ \vdots & \ddots & \vdots \\ g(\omega_1 \cdot x_N + b_1) & \cdots & g(\omega_k \cdot x_N + b_k) \end{bmatrix}, \; \beta = \begin{bmatrix} \beta_1^T \\ \vdots \\ \beta_k^T \end{bmatrix}_{k \times m} \text{ and } T = \begin{bmatrix} t_1^T \\ \vdots \\ t_N^T \end{bmatrix}_{N \times m} \quad (3)$$

As mentioned in Huang et al. [5], H is named the hidden layer output matrix of the neural network; the ith column of H denotes the ith hidden node output with respect to inputs $(x_1, x_2, \ldots, x_N)$.

With these notations, the hidden-layer output matrix can be determined:

$$\beta = H^{\dagger} \times T \quad (4)$$

Where $H^{\dagger}$ is the Moore-Penrose generalized inverse of matrix H [6]. Owing to the Moore-Penrose generalized inverse, the learning speed of ELM net is dramatically increased.

B. Deep Structure Extreme Learning Machine (DS-ELM)

As ELM described above, it can avoid many difficulties faced by gradient-based learning technique. While, in order to improve the ability of removing noise of ELM, deep structure extreme learning machine (DS-ELM) is proposed, and this new algorithm can deal with the noisy data with very high accuracy. DS-ELM contains two subnets based on AANN and an ELM net. And Fig.1 shows the procedure of establishing the DS-ELM, and the following is the procedure of DS-ELM algorithm:

(1) Calculating the first hidden layer based on AANN algorithm aim to filter the noise of input data. Auto-associative neural network (AANN) was proposed by Kramer in 1992 [7], which is an unsupervised learning algorithm that applies back-propagation, setting the target values to be equal to the inputs. It tries to learn an approximation to the identity function, that is, the output is similar to the input, so as to filter the noise of input data and learn an equal representation of sample attributes. After the AANN net is trained well, the weights between the input layer and the hidden layer should be kept unchanged, and the output layer will be excluded, then, the remaining part of the well-trained AANN is used as the first net.

(2) Determining the weights and bias of input layer and hidden layer of ELM by the second AANN layer. The input output data of this AANN net is the output of hidden layer of the first AANN net. After the well-trained the second AANN subnet, the weights between the input layer and the hidden layer should also be kept unchanged, which will be used as the hidden weights and bias of ELM aim to avoid the hidden layer output matrix not full column rank.

(3) Training the ELM model. The output data of hidden layer of the first AANN net is regard as the input data of ELM. And the output data of ELM is the sample data. The weights and bias between input layer and hidden layer of ELM is that of the second AANN. After the well-trained ELM, the whole system of DS-ELM model is finished. It can be found the procedure of establishing the DS-ELM model is simple in implementation.

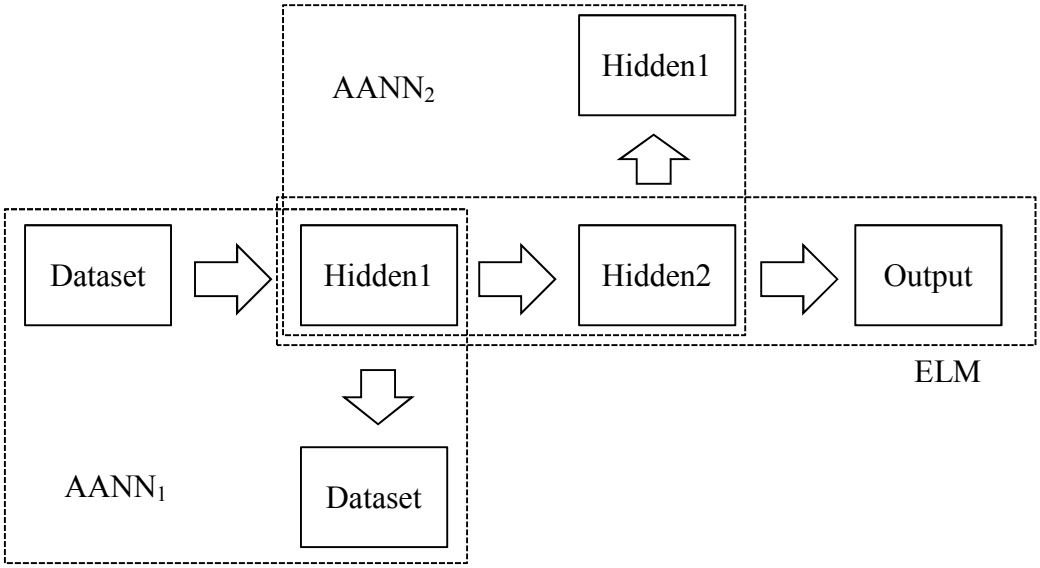

Fig.1 The structure of DS-ELM

Experiments

The DS-ELM model aims to improve the efficiency of ELM for noisy data. In this part, altogether four dataset are selected from UCI to examine the proposed DS-ELM model. In addition, 10 percent of white noise is added to all the four datasets. The different information for the datasets is summarized in Table 1.

Table 1 Information about the selected data sets.

Data set	# Attributes	# Train	# Test
Iris	5	120	30
Wine	13	89	89
Housing	13	338	168
Abalone	8	2000	2177

In order to compare the new proposed DS-ELM method with ELM method on classification and regression problems, an adequate error measure method must be selected. In this paper, the root mean squared error (RMSE) is used as the error criterion for regression problems, and accuracy of predict is used for the classification problems. And the RMSE is computed as follows:

$$\mathrm{RMSE} = \sqrt{\frac{\sum_{i=1}^{N}(y_i - t_i)^2}{N}} \tag{5}$$

Where N expresses the total number of samples in the test set, t_i is the real values and y_i is the output predicted by the DS-ELM model.

Table 2 The optimal results comparison between the proposed DS-ELM and ELM.

Dataset	Type	DS-ELM	ELM
		RMSE or Accuracy (%)	RMSE or Accuracy (%)
Iris	classification	96.67%	93.33%
Wine	classification	98.87%	96.63%
Housing	regression	6.0251	6.5237
Abalone	classification	96.46%	95.36%

Table 2 summarizes the type of problems (regression or classification) and the prediction performance (RMSE or accuracy) of DS-ELM and ELM model. Compared with ELM, it is obvious that DS-ELM provides a smaller value of RMSE or higher classification accuracy, that is, AD-ELM method outperforms the ELM method. That because AANN net removes noise of input data firstly, and then fixes input weights and bias of ELM which avoid the instability of ELM net.

Summary

In this paper, we have addressed the task of trying to improve the performance of ELM model for noisy data. ELM as a higher generalization performance than the traditional gradient-based learning algorithms, but when faced noisy data, the performance of ELM is needed to be improved. The new proposed DS-ELM model can filter noise of input data firstly, and then fix the input weights and bias of ELM, which makes the whole system becomes more stability and superior. So, DS-ELM is a better choice for the datasets with noisy.

Keywords: Motion simulation platform, Closed-loop vector method, Laser communication, Airborne.

Abstract. Lightweight, flexible motion simulation is the demand of airborne laser communication optical transceive when apply to outside test. A new parallel 2_DOF platform that has the function of azimuth and pitching is put forword based on the analysis of airplane position-pose changes affect the performance airborne laster communication APT system, and the kinematics model is established by using closed-loop vector method. Kinematics model is right through the comparison of mathematical model and simulation results of ADAMS, which provides the reference and basis for the design of control system.

Introduction

Wireless laser communication has the advantages of high-speed and large-capacity communication, anti-interference, anti-interception, security and the system needs small volume, small mass and low consumption. Meanwhile it is an important pattern in High-speed data transmission and wideband transmission in the future, also it's one of the most promising mode in communication. As the base of space laser communication, the acquisition, pointing and tracking subsystem is the first coming problem needs to be solved when starting the work on space laser communication.

Most of the laser communication platforms are mobile, the stability in motion and the change in gesture are two factors that restrict the performance of APT system. Among these mobile platform, the planes are the maximum mobility in the laser communication link. The effect of plane on tracking-pointing mechanism lie in high-frequency vibration and low-frequency posture change, and high-frequency vibration affect the stability of tracking-pointing mechanism while Low frequency swing affect the tracking performance [1,2]. Therefore, in the process of design and develop tracking-pointing mechanism, both low-frequency motion and high-frequency vibration in plane should be taken into consideration. Detecting the performance of APT system is an important method to improve the accuracy of APT system, and the best way is to detect its accuracy in real environment, however, it's almost impossible in the research on laser communication. The usual method is simulating movement characteristics of the carrier platform.

For far distance laser communication, a main factor affecting the performance of APT system is the posture change of carrier platform. Since laser communication is not imagining observation system, the effect of rotation of axis on performance of the system can be ignored, therefore the rotation of 2-DOF truly affect the performance of APT system. The common simulation platform in use are frame structure and parallel structure. Frame structure has advantage in control accuracy and velocity, but its structure is flexible and its capacity is small, also the location which place tasted parts is limited, the field of view can be occluded. Parallel structure is much compact and its capacity is bigger, in addition, the field of view can't be occluded, so parallel structure is first choice for simulating outfield motion.

Test about The Posture of Plane and Analysis of 2_DOF's Indicator

For control unit of coarse fine composite shaft of APT system, tracking accuracy,tracking velocity and tracking acceleration are mutual restraint. To acquire tracking accuracy, guaranteed precision angular velocity must be restricted [3,4]. When guaranteed precision angular velocity and guaranteed precision angular acceleration were given, the dynamic lag errors of the system is

$$\sigma_d = \sqrt{(\frac{\Omega}{K_v})^2 + (\frac{\varepsilon}{K_a})^2} \tag{1}$$

Where Ω is angular acceleration for relative movement, ε is angular velocity for relative movement, K_v is velocity quality coefficients for tracking system and K_a is acceleration quality coefficients for tracking system. As showing Eq. 1, the value of dynamic lag errors depends on both characteristics of tracking system and original incentive.

The low-frequency posture change of carrier platform can be measured by INS, the result is showed in Fig. 1.

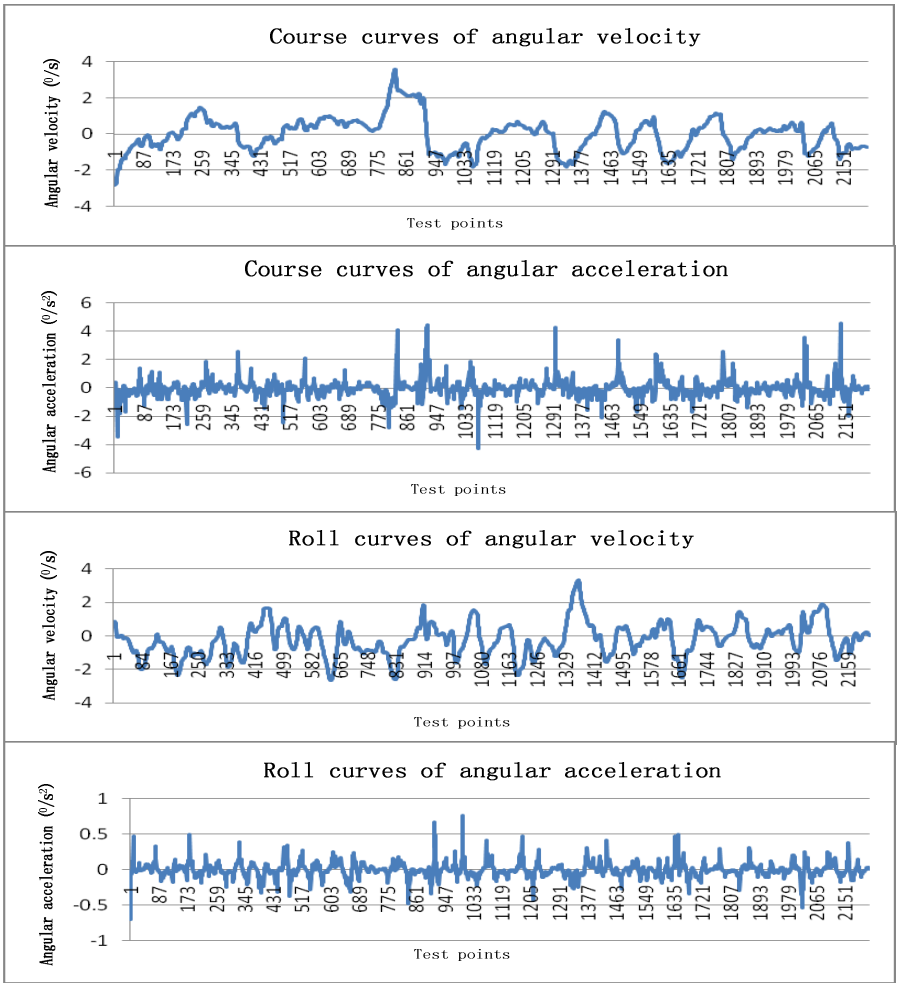

Fig. 1 Shows maximum posture change for tested carrier

Plane is about 6°/s ,and maximum acceleration is about 5°/s^2, in which, course correspond to direction of simulation platform and roll correspond to pitching of simulation platform. So considering the extension application of equipment, maximum simulating velocity of 2-DOF simulation tested rolling platform is 20°/s, maximum simulating acceleration is 20°/s^2, maximum range of motion is 15°.

2_DOF Parallel Simulation Platform's Design

Fig. 2 shows the structural diagram of the 2-DOF motion simulation platform, the system consists of moving platform, middle supporting platform (including 4 auxiliary support rods), center support, static platform, constraint rod A, servo electric cylinder A, B, C, and support beam of both ends (C_0C_1 and C_2C_3) plus 4 jointing hinges. The moving platform and middle supporting platform are connected by 4 support rods, the middle supporting platform and the static platform are connected by center support which installs the D2 self-lubricated spherical bearing, the center support link up to static platform by fixed point D1. The static platform, the self-lubricated spherical bearing, the middle supporting platform, and the moving platform are paralleled to each other, of which their centers are concentric. Constraint rod A and servo electric cylinder B are paralleled to the center axis O_1, O_2, O_3, O_4 of the simulation platform, perpendicular to the servo electric cylinder C. Joint A_2 and B_2 which connected to moving platform by spherical hinge are distributed at right angles in a circle which radius is R_0, joint C connected to the middle supporting platform by spherical hinge, joint A_1 and B_1 which connected to the static platform by Hooke through point C_1 are also distributed at right angles in the circle which radius is R_0. Servo electric cylinder B and C move at the same time to get the compound movement of azimuth and elevation of the simulation platform, this parallel mechanism has 2-DOF which is equal to the drive number, so there is no actuation redundancy.

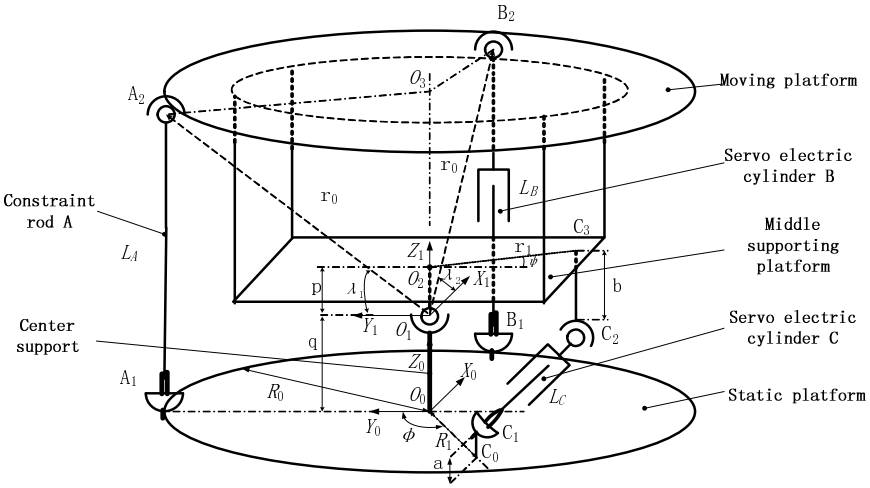

Fig. 2 2_DOF Structure of parallel simulation platform

We can establish a coordinate as shown in fig .2 firstly, then establish base coordinate O_0-$X_0Y_0Z_0$ in static platform and center coordinate O_1-$X_1Y_1Z_1$ in the center of the whole simulation platform of which the axes parallel to the other respectively in initial state. Supposing started at the initial position, the elevation rotates α degree around the Y_0 axis and the azimuth rotates β degree around the Z_0 axis then we get the current attitude coordinate (α,β), under Kaerdan angle coordinate transform relations [5,6,7] (Kaerdan angle applies to smaller angular transformation), in base ordinate any point E of the moving platform gets a coordinate vector $\overrightarrow{{}^0P_e}$:

$$\overrightarrow{{}^0P_e} = T\overrightarrow{{}^1P_e} + \overrightarrow{P_0} \tag{2}$$

Where, $\overrightarrow{{}^1P_e}$ is the coordinate degree of point E in the center coordinate, $\overrightarrow{P_0}$=(0,0,q) is the position vector of the center coordinate origin O_1 in the base coordinate, q is the vertical distance from O_1 to O_0, T is the direction cosine matrix from center coordinate O_1-$X_1Y_1Z_1$ to base coordinate O_0-$X_0Y_0Z_0$:

$$T=\begin{bmatrix}\cos\alpha\cos\beta & -\cos\alpha\sin\beta & \sin\alpha\\ \sin\beta & \cos\beta & 0\\ -\sin\alpha\cos\beta & \sin\alpha\sin\beta & \cos\alpha\end{bmatrix}$$

Setting the total length of the servo electric cylinder B and C at l_B and l_C respectively, and expressed as vector form is $\vec{l_B}=\overrightarrow{B_1B_2}$, $\vec{l_C}=\overrightarrow{C_1C_2}$, and we can get the position vector of points B_2 and C_2 in base coordinate O_0-$X_0Y_0Z_0$ according to closed loop vector method:

$$\overrightarrow{{}^0P_{B_2}}=\overrightarrow{O_0B_1}+\overrightarrow{B_1B_2}=\overrightarrow{O_0O_1}+\overrightarrow{O_1B_2} \tag{3}$$

$$\overrightarrow{{}^0P_{C_2}}=\overrightarrow{O_0C_0}+\overrightarrow{C_0C_1}+\overrightarrow{C_1C_2}=\overrightarrow{O_0O_1}+\overrightarrow{O_1O_2}+\overrightarrow{O_2C_3}+\overrightarrow{C_3C_2} \tag{4}$$

Simplify it we can get:

$$\vec{l_B}=T\overrightarrow{{}^1P_{B_2}}+\vec{P_0}-\vec{R_0} \tag{5}$$

$$\vec{l_C}=T\overrightarrow{{}^1P_{C_2}}+\vec{P_0}-\vec{R_1}-\vec{a} \tag{6}$$

Where, $\vec{R_0}$ is the direction vector from O_0 to B_1, $\vec{R_1}$ is the direction vector from O_0 to C_0, $\vec{a}$ is the direction vector from C_0 to C_1, modulus on both sides we can get :

$$\left|\vec{l_B}\right|=\left|T\overrightarrow{{}^1P_{B_2}}+\vec{P_0}-\vec{R_0}\right| \tag{7}$$

$$\left|\vec{l_C}\right|=\left|T\overrightarrow{{}^1P_{C_2}}+\vec{P_0}-\vec{R_1}-\vec{a}\right| \tag{8}$$

The coordinate degree of B_2 and C_2 in center coordinate is ${}^1P_{B_2}$ $(r_0\cos\lambda_2,0,r_0\sin\lambda_2)^{\mathrm{T}}$, ${}^1P_{C_2}$ $(r_1\sin\psi,-r_1\cos\psi,p-b)^{\mathrm{T}}$, among which r_0 represents the distance from the origin of center coordinate O_1 to hinge point B_2, r_1 represents the distance between the origin of center coordinate O_1 and hinge point C_2, b represents the vertical distance from hinge point C_2 to middle supporting platform, p is the distance from the center of middle supporting platform to the rotating center O_1 of simulation platform, λ_2 is angle between $\overrightarrow{O_1B_2}$ and X_1 axis, φ is angle between $\overrightarrow{O_0C_0}$ and -Y0 axis, ψ is angle between $\overrightarrow{O_2C_3}$ and -Y_1 axis, the rod length l_B and l_C changing with the angle formula can be settled when we substituting all above to Eq. 7 and Eq. 8:

$$\left|l_B\right|^2=\sqrt{\begin{aligned}&\left|\cos\alpha\cos\beta\cdot r_0\cos\lambda_2+\sin\alpha\cdot r_0\sin\lambda_2-R_0\right|^2+\left|\sin\beta\cdot r_0\cos\lambda_2\right|^2+\\&\left|-\sin\alpha\cos\beta\cdot r_0\cos\lambda_2+\cos\alpha\cdot r_0\cos\lambda_2+q\right|^2\end{aligned}} \tag{9}$$

$$\left|l_C\right|^2=\sqrt{\begin{aligned}&\left|\cos\alpha\cos\beta\cdot r_1\sin\psi+\cos\alpha\sin\beta\cdot r_1\cos\psi+\sin\alpha\cdot(p-b)+R_1\sin\phi\right|^2+\\&\left|\sin\beta\cdot r_1\sin\psi-\cos\beta\cdot r_1\cos\psi+R_1\cos\phi\right|^2+\\&\left|-\sin\alpha\cos\beta\cdot r_1\sin\psi-\sin\alpha\sin\beta\cdot r_1\cos\psi+\cos\alpha\cdot(p-b)+q-a\right|^2\end{aligned}} \tag{10}$$

Kinematics Simulation

According to technical indicators of the simulating platform, original structure parameters on simulating platform are setting as: the height between moving platform and static platform is(the length of restraint rod) 315mm, $R_0 = 185mm$, p = 33.5mm, through the simulation calculation and structure optimization, deducing the rest of the parameters: q = 106.5mm a = 85mm, $r_1 = 125mm$, b = 55, $r_0 = 278.7423mm$, $\lambda_2 = 48.41767^\circ$, $\phi = 110.6032^\circ$, $\psi = 53.1301^\circ$, $R_1 = 213.1320mm$.

To test the acquisition, pointing and tracking performance of airborne optical transmitter, 2-DOF simulation platform locomotes follows the change laws of azimuth α and pitching angle β. According to posture change of plane, equivalent sine for azimuth and pitch posture are:

$$\alpha = 12\sin(\frac{1}{2}t) \tag{11}$$

$$\beta = 5\sin(t) \tag{12}$$

Without considering error in joint clearance, setting up math model of simulating platform by numerical analysis software MATLAB, taking Eq. 11 and Eq. 12 into Eq. 9 and Eq. 10, we get change curves of the length of rod B, C in servo electric cylinder, meanwhile setting up 3D models of 2-DOF simulation platform by dynamics simulation software ADAMS [8,9], as showing in Fig. 3.

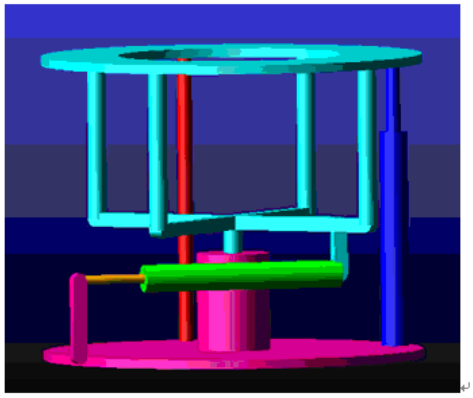

Fig. 3 The model of parallel simulation platform

Input the change laws of azimuth α and pitching angle β, simulation time is 30s, we get change curves of rod in servo electric cylinder by measuring the location changing of both ends. The computation result of maths model set by MATLAB and simulation result of 3D models set by ADAMS are shown in Fig. 4 and 5.

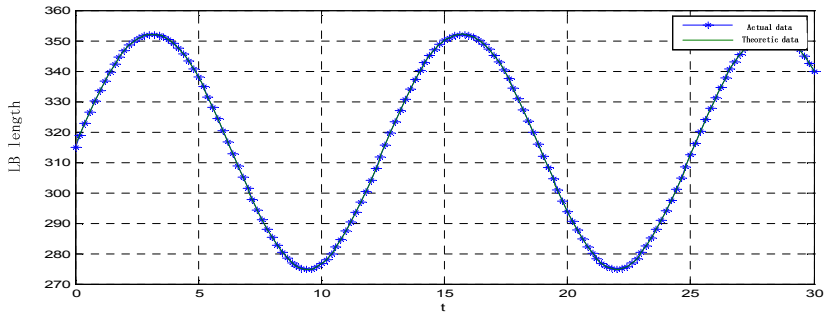

Fig. 4 The changing curve of servo electric cylinder B

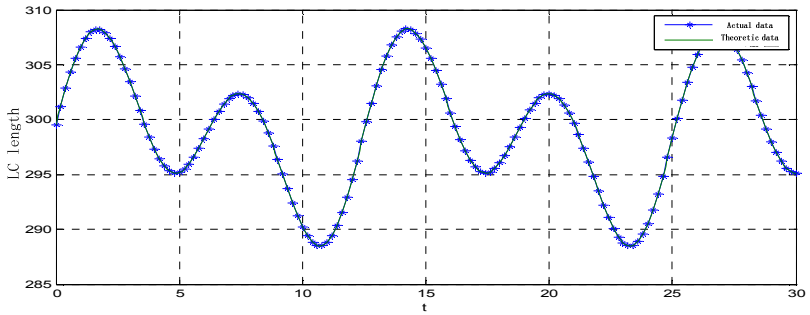

Fig. 5 The changing curve of servo electric cylinder C

The comparison analysis of length change get by mathematics modeling and physical machine simulating, two change curves of the length of rod in servo electric cylinder are consistent, indicating the setting maths model is right. Taking the data of the length change of rob calculated by MATLAB into spline made by ADAMA, loading the spline on two electric cylinders, measuring the change laws of azimuth and pitching angle, the result is exactly anastomotic with preestablished α and β. Through analyzing positive and negative solution of the results, it's indicating that the structure design of 2-DOF simulation platform is feasible both in theory and applications, providing math model for the design of next generation control system.

Conclusion

By setting and simulating math model of 2-DOF movement simulative platforms, the platform enable landing platform to motion in pitch and azimuth, meeting the testing requirements of posture change in APT system of airborne laser communication. In the meantime, since it has 2-DOF, controlling system is much simpler, the structure is light, small and simple, and it's very convenient for testing in external field.

Key words: kernel density estimation, histogram, optimal group, the close degree

Abstract. The optimal group is an important problem of histogram algorithm, and how to confirm group number has not a quantitative rule. So the concept of the close degree is imported to make the close degree between the upper contour line of histogram and the PDF(probability density function) of parameter as the judging criteria of optimal group. With the unknown of the PDF of parameter, the improved kernel density estimation algorithm can pre-select and estimate the PDF. This improved kernel density estimation algorithm combine the selection of fixed window and variable window's width to achieve the window's width automatic adjustment value between the different estimation points based on the sample distribution. In the parameter analysis of radar emitter signal, the algorithm based on improved kernel density estimation and close degree is used to determine optimal group, and the result indicate that this method is effective and can search the optimal group automatically.

Introduction

The histogram algorithm has visual concept and can achieve simply, but it need to solve two major problems: Data range extension and optimal group. The optimal group problem is more critical, because it is a complex and difficult problem by the effectiveness of histogram[1].So In the paper, the concept of close degree is introduced to solve this problem. According to the probability density curve that the parameters obey, the close degree between the histogram upper contour line and the parameter probability density function is calculated to be the judging criteria of optimal group. If the parameter probability density function doesn't know, kernel density estimation can be used.

The optimal group principle based on the close degree

A T is a set of a real parameter observation data, the interval A is the parameter range, $\delta_i (i = 1,2\cdots, N)$ is the subinterval of A and f_i called frequency is numerical number of which in interval T fall into the subinterval δ_i .Among them, δ_i and f_i respectively satisfy the following conditions:

(1)For arbitrary i and j $(i = 1,2,\cdots, N; j = 1,2,\cdots, N; i \neq j)$, the intersection between δ_i and δ_j is empty, that is $\delta_i \cap \delta_j = \phi, \phi$ is empty set.

(2) $\bigcup_{i=1}^{N} \delta_i = A$

According to specific situation, the width of $\delta_i (i = 1,2\cdots, N)$ can be equal and can also not be equal. To make N rectangles called histogram with the width of subinterval δ_i and f_i as side length. Taking the parameter values range as the transverse, the frequency as the longitudinal axis, and placing each histogram in transverse according to relevant δ_i, so the graphic made like this is called histogram.

Normalizing the histogram, and making $f_i' = \frac{f_i}{N}$,let the upper contour line of the normalized histogram function be $f(x)$, as shown in figure 1.The probability density function that the parameters obey is $p(x)$,and define the close degree between $f(x)$ and $p(x)$ is:

$$\sigma = \frac{\int_{-\infty}^{+\infty} \min[f(x), p(x)]dx}{\int_{-\infty}^{+\infty} \max[f(x), p(x)]dx} \tag{1}$$

The smaller close degree explains the upper contour line of histogram and parameter probability density function are closer and the group is better at the moment; the bigger close degree explains the upper contour line of histogram and parameter probability density function are far and the group is not optimal at the moment. If the probability density function of the parameters is unknown, kernel density estimation methods can be used to estimate.

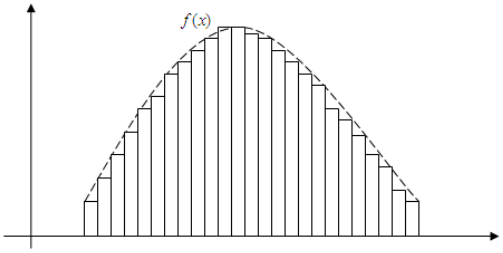

Figure1 The diagram of normalized histogram upper contour line

Improved kernel density estimation algorithm

$X_1, X_2, \cdots, X_n$ is the sample of the same independence distribution pumped from one dimension X , X has the unknown probability density function $p(x)$, $x \in R$,the kernel density estimation of $p(x)$ is[2]:

$$\hat{p}(x) = \frac{1}{nh}\sum_{i=1}^{n} K(\frac{x - X_i}{h}) \tag{2}$$

n is number of the sample set; $K(u)$ is the kernel density estimation function, referred to as kernel function; h is the window width that decides the variance of the kernel function. The selection of window width is the key to the success of the kernel density estimation. The selection of optimal window width can be divided into two categories: the fixed window width and the variable window width.

The fixed window width assumes that the real density $p(x)$ obeys the distribution of $N(\mu, \sigma^2)$ and make the error between density estimation and the real density minimum, then the optimal window width can be got[3] [4]:

$$h_{opt} = 1.059\sigma n^{-\frac{1}{5}} \tag{3}$$

$\sigma = [\frac{1}{n}\sum_{i=1}^{n}(x_i - \bar{X})]^{1/2}$, n is the number of the sample, $\bar{X}$ is the average of the sample set.

The variable window width begins from the error between the density estimation and the real density, makes minimum h of the mean square error between the density estimation and the real density as the optimal window width.

$$MSE(h_0) = E[\hat{p}(x) - p(x)]^2 \tag{4}$$

To get the optimal window width through the minimization of $MSE(h_0)$:

$$h^*(x) = n^{-1/5}[(k_2 p''(x))^{-2} p(x)\int_{-\infty}^{\infty} K^2(u)du]^{1/5} \tag{5}$$

$k_2 = \int_{-\infty}^{\infty} u^2 K(u)du$ .The value of $h^*(x)$ is related to the density estimation point x from equation (5) , its value changes with the different estimate points, when using the result of the above equation to solve the distribution density of x , the window width value changes with x, the variable window width can better reflect the smooth degree of the different points in estimated interval , reduce the fitting curve deviation in the top area and improve the flexibility of the fitting curve[5]. But the true density is unknown, or there is no need to estimate. So $h^*(x)$ can't be calculated. Another processing method is equal to the fixed window width selection, supposing a real density. Yet for an unknown distribution, the probability density function through the kernel density estimation, in most cases, should be closer to the actual than a hypothetical distribution. Therefore, the improved kernel density estimation method can be got through combining fixed window width selection and the variable window width selection, the specific steps are as follows:

(1)Calculating the fixed optimal window width h_{opt} according to formula (3);

(2)Calculating the real density estimation $\tilde{p}(x)$ according to formula (2);

(3)Calculating the variable window width $h^*(x)$ using $\tilde{p}(x)$ to replace the real density $p(x)$ according to formula (5);

(4)Calculating the final probability density estimation $\hat{p}(x)$ through using $h^*(x)$ as window width according to formula (2).

The simulation results

It is applied to analysis the basic parameters pulse repetition period of radar emitter signals (PRI) to test the validity of the histogram algorithm based on kernel density estimation. The value of the repetition cycle fixed type is set as 50 ms; The center value of repeat cycle jitter types is 50 ms; The values of repeat cycle three principal types are 50 ms, 100 ms, 150 ms; The values of repeat cycle agile or sliding variable are 40ms, 42.5ms, 45 ms,47.5 ms, 50ms ,52.5ms, 55ms, 57.5ms,60ms. Each type of simulation has 500 samples, and set the measurement error of 1%. The probability density function is estimated which the parameters are obeyed before analysis of the parameter by using the improved kernel density estimation algorithm.

The close degree is $\sigma_{th} = 0.85$ in the experiment. Using the following method to determinate data range extension: calculating the average of the samples $\overline{x} = \frac{1}{n}\sum_{i=1}^{n} x_i$ and the standard deviation $S_x = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n}(x_i - \overline{x})^2}$, then the lower limit value of the parameters can be $(x_{\min} - w' \times S_x)$ and the upper limit value can be $(x_{\max} + w' \times S_x)$, $x_{\min}$ and $x_{\max}$ are the minimum and maximum of $x_i (i = 1, 2 \cdots n)$, $w' = 0.25$ in the experiment. There adopt equidistant grouping in experiment, when the close degree between the top contour line function of the histogram and the probability density function is less than the threshold σ_{th}, stop searching. At the moment, the close degree and the group number are as shown in table 1, the probability density curve and the histogram of the optimal grouping are as shown in figure 2 and figure 5. Histogram can clearly reflect the work type of parameters and the value when the optimal number is got from the graph.

Table1 The optimal group and close degree of different type PRI

Work type	Optimal group	Close degree
Fixed	7	0.8847
Stagger	21	0.8792
Jitter	16	0.9245
Agility	27	0.9143

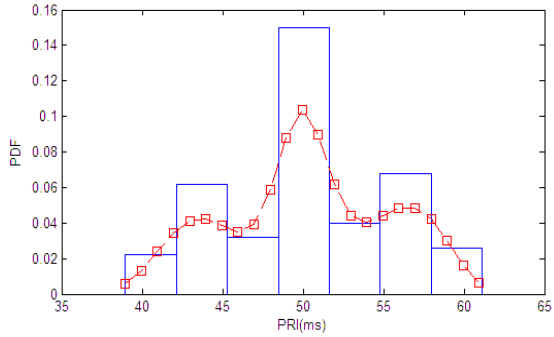

Figure2 The probability density curve and the histogram of the fixed PRI

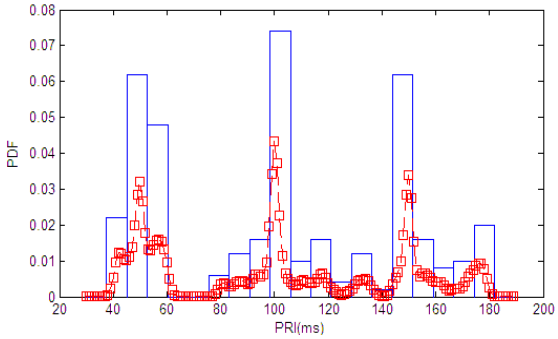

Figure3 The probability density curve and the histogram of the three stagger PRI

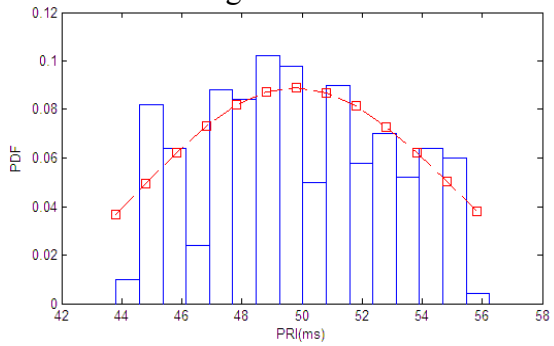

Figure4 The probability density curve and the histogram of the jitter PRI

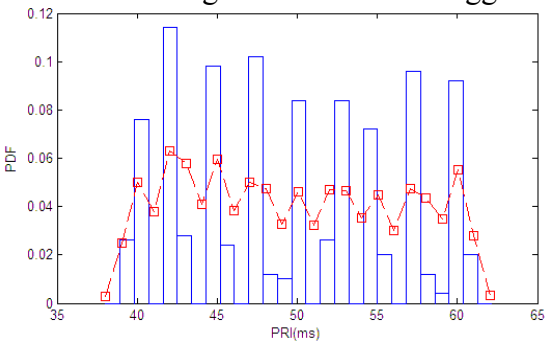

Figure5 The probability density curve and the histogram of the agility PRI

Conclusion

The concept of close degree is introduced to solve the problem of optimal grouping of histogram method. The close degree between the upper profile of histogram and the probability density function that parameters obey is the decision criteria of the optimal grouping. The probability density function of parameters can be primarily got by making use of the improved kernel density estimation algorithm with the variable window width. The histogram algorithm based on the improved kernel density estimate and the close degree is applied to analysis the basic parameters of radar emitter signals PRI, and the results show that this method can quantitatively get the optimal grouping number.

Key words: FH communication; arbitrary array; CTMV; SINR

Abstract. Aiming at the problem of poor performance of suppressing the wide band jamming and fast following jamming in Frequency-Hopping(FH) communication system, a communication scheme by combination of the complementally transformed minimum variance with FH technique for arbitrary array(CTMV-FH) is proposed, based on the purpose to maximize the output Signal to Interference and Noise Ratio (SINR). Basic theory of CTMV is introduced. The algorithm is used to suppress the wide band jamming and fast following jamming. Simulation results show that the scheme can suppress the wide band jamming and fast following jamming effectively in FH communication system.

Introduction

Frequency-Hopping(FH) communication has strong ability of anti-jamming and anti-interception, which is widely used in the military communication, such as satellite FH communication and VHF radio FH communication. The wide-band jamming and fast follower jamming are the main threate for the FH communication [1]. The combination of adaptive nulling antenna with FH technique is first proposed to improve the ability of anti-jamming by Faik Eken [2]. Qiu and Montse Najar are further studying on the FH system with the wide-band jamming[3-5]. But they are not considering the case that the wide-band jamming and fast follower jamming are existing at the same time. In [6] [7], to this case, a combination of the eigenspace-based beamformer(ESB) with spatial smoothing algorithm(SS) is proposed [8]. The technique can suppress the wide-band jamming and fast follower jamming with array aperture reduction and effective element loss. An improved SS is proposed in [9] [10], which can suppress the wide-band jamming and fast follower jamming without array aperture reduction and effective element loss. But the technique of SS can only be used in the uniform linear array, it is invalid for arbitrary array. In [11], the complementally transformed minimum variance beamformer(CTMV) is used to suppress the coherent interference for arbitrary array, which obtains a well results.

In this paper, a communication scheme by combing of CTMV with FH technique for arbitrary array is proposed (CTMV-FH). Then system model of the scheme is introduced. Some necessary background is presented in next chapter. Then CTMV is presented for suppressing the wide-band jamming and fast follower jamming. Several simulation examples will illustrate the effectiveness of the proposed method. Conclusions are given in final chapter.

System model

The combination of adaptive nulling antenna with FH technique can discriminate the signal and interference in spatial-frequency domain, which can be further improve the ability of anti-jamming. The structure of CTMV-FH system is shown in Fig.1.

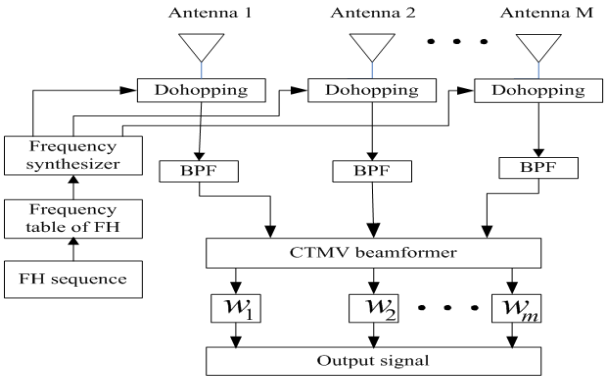

Fig.1 Structure of CTMV-FH system

The signal is received by RF of each array element. Firstly, the signal goes through the dehopping module. Secondly, the intermediate frequency signal is obtained by taking the dehopping signal through band pass filter(BPF). Finally sampling the intermediate frequency signal and taking it into adaptive beamforming module. Because the time-resident of each hop is very short, the adaptive beamforming algorithm must have fast convergence speed. So CTMV is used to suppress the wide-band jamming and fast follower jamming for arbitrary array.

Background

The wide-band jamming and fast follower jamming are seen as uncorrelated interferer and coherent interferer in the FH system, respectively. Consider a desired signal, P uncorrelated interferers and Q coherent interferers impinging on an M-element arbitrary antenna array from θ_0, θ_i and θ_j, respectively. The received complex-valued data vector $X(t)$ can be expressed as

$$X(t) = a(\theta_0)s_0(t) + \sum_{i=1}^{P} a(\theta_i)s_i(t) + \sum_{j=P+1}^{P+Q} a(\theta_j)s_j(t) + n(t) \tag{3-1}$$

Where $s_0(t)$, $s_i(t)$ and $s_j(t)$ denote the waveforms of the desired signal, the ith coherent interferer and jth uncorrelated interferer, respectively. $a(\theta)$ denotes the steering vector. $n(t)$ is an additive white Gaussian noise (AWGN) vector.

Based on the maximum SINR principle, the optimal weight vector can be given as

$$W_{opt} = \alpha R_{i+n}^{-1} a(\theta_0) \tag{3-2}$$

Where α is a constant and R_{i+n} is the interference-plus-noise covariance matrix.

So far, some adaptive beamforming algorithms such as direct matrix inversion(DMI) and eigenspace-based beamforming(ESB) can only obtain approximate value of R_{i+n} without the coherent interferer. SS and its improved algorithm can obtain a well approximate value with the coherent interferer, but these algorithms just apply to uniform linear array. For this purpose, CTMV is used to obtain R_{i+n} for arbitrary array with the coherent interferer.

CTMV

The desired signal is removed from the array data with other coherent interferers unchanged by using a linear transformation in CTMV[11].

Considering that there is a linear transformation $T(M \times M)$, it satisfying

$$Ta(\theta_0) = 0, Ta(\theta_i) = a(\theta_i), i = 1, 2, ..., P \tag{4-1}$$

The transformed data

$$TX(t) = \sum_{i=1}^{P} a(\theta_i)s_i(t) + \sum_{j=P+1}^{P+Q} Ta(\theta_j)s_j(t) + Tn(t) \tag{4-2}$$

Except for the desired signal, the only difference between (4-2) and (4-1) is the uncorrelated interference and noise. Thus, the transformation should minimize the impact on uncorrelated interference and noise. In other words, the transformation should minimize the error between the original data and the transformed data

$$E[\|TX - X\|^2] = tr[(T - I) R_x (T - I)^H] \quad (4\text{-}3)$$

Where R_x is the covariance matrix. $E[\bullet]$, $\|\bullet\|$ and $tr[\bullet]$ denote the expectation, the vector two-norm and trace operator, respectively.

The linear transformation can be solved by using Lagrange multiplier.

$$T = I - (A - B)(A^H R_x^{-1} A)^{-1} A^H R_x^{-1} \quad (4\text{-}4)$$

Where $A = [a(\theta_0), a(\theta_1), a(\theta_2), ..., a(\theta_P)]$ and $B = [0, a(\theta_1), a(\theta_2), ..., a(\theta_P)]$.

Then (4-5) is proved in [11]

$$Ta(\theta_j) = a(\theta_j) - (A - B)(A^H R_x^{-1} A)^{-1} A^H R_x^{-1} a(\theta_j) \approx a(\theta_j), j = P+1, P+2, ..., P+Q \quad (4\text{-}5)$$

Thus, the uncorrelated interference almost invariably by using the linear transformation .

To remedy the sensitivity problem, R_x should be modified into a better conditioned form. The diagonal loading algorithm is the simple method to decrease the sensitivity problem. Thus,

$$\overline{R}_x = R_x + \lambda I \quad (4\text{-}6)$$

Where λ and $I(M \times M)$ denote the diagonal loading factor and identity matrix, respectively. Finally, we obtain the linear transformation T

$$T = I - (A - B)(A^H \overline{R}_x^{-1} A)^{-1} A^H \overline{R}_x^{-1} \quad (4\text{-}7)$$

Combining with (3-2), the weight vector is

$$W = (TR_x T^H)^{-1} a(\theta_0) / (a^H(\theta_0)(TR_x T^H)^{-1} a(\theta_0)) \quad (4\text{-}8)$$

The weight vector is solved by (4-8) can raise two problems. Firstly, the correlation matrix $TR_x T^H$ is not always singular. Secondly, the noise component in $TR_x T^H$ is no longer the same as in the original R_x. So the noise part in $TR_x T^H$ should be replaced by $\sigma_n^2 I$

$$\widetilde{R}_x = TR_x T^H - \sigma_n^2 TT^H + \sigma_n^2 I \quad (4\text{-}9)$$

Finally, we obtain the weight vector

$$W = \tilde{R}_x^{-1} a(\theta_0) / (a^H(\theta_0) \tilde{R}_x^{-1} a(\theta_0)) \quad (4\text{-}10)$$

Through the above analysis, we can find that combining CTMV with FH can effective suppress the wide-band jamming and fast follower jamming. Computer simulation results will demonstrate performance of the proposed scheme in next chapter.

Simulations Results

In this section, simulation results are presented to demonstrate the performance of the proposed scheme. Considering a FH system, it works from 30MHz to 90MHz. Choose three points of frequency hopping random. Assuming the three points are {30, 40, 50} *MHz*. In order to compare with virtual spatial smoothing algorithm (VSS), the array element locations are {0, 3, 6, 9, 12, 15, 18, 21} *m*. The desired signal with SNR of 0dB impinges from $\theta_0 = 0^\circ$. The wide-band jamming and fast follower jamming with INR of 30dB impinge from $\theta_1 = 40^\circ$ and $\theta_2 = -20^\circ$, respectively. The diagonal loading factor is 10. The number of snapshots of each point of FH is 200. All results are averaged based on 100 independent Monte Carlo simulation runs.

A. Only existing the wide-band jamming

Tab.1 is the comparison of different algorithms with the wide-band jamming (the third point of FH for example). Clearly, the output of CTMV is higher than DMI and ESB, and it is closer to optimum value. Fig.2 shows the output SINR versus number of snapshots of different algorithms in three points of FH with the wide-band jamming. It can been seen that CTMV has a better

convergence speed than DMI and ESB. Fig.3 shows comparison of the beampatterns with the wide-band jamming(the third point of FH for example). Combining with Tab.1, the nulling of CTMV is deeper than DMI and ESB. Therefore, CTMV has a better performance than DMI and ESB with the wide-band jamming in FH communication system.

Tab.1 Comparison of different algorithms with the wide-band jamming

Gain/dB	DMI	ESB	CTMV	Optimum
$F(\theta_1)$	-57.1	-55.5	-59.7	-94.7
Output SINR/dB	7.9	8.5	8.8	8.9

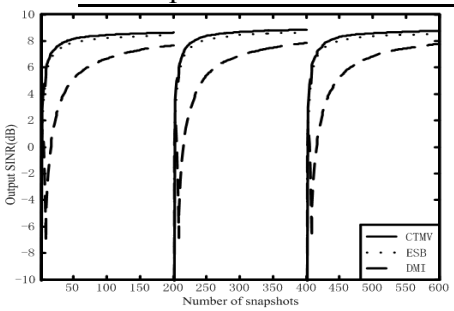

Fig.2 Output SINR versus number of snapshots with the wide-band jamming

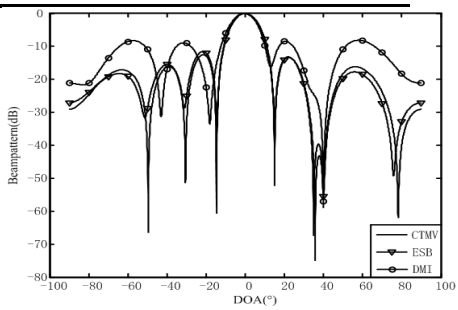

Fig.3 Comparison of the beam-pattern with the wide-band jamming

B. Existing compound interferences

Tab.2 is the comparison of different algorithms with the compound interferences (the third point of FH for example). Clearly, because of the coherent interferer, DMI and ESB can not obtain high output SINR. Opposite, VSS and CTMV can also achieve high output SINR and the latter is higher than the former. Fig.4 shows the output SINR versus number of snapshots of different algorithms in three points of FH with the compound interferences. It can been seen that CTMV has a faster convergence speed and higher output SINR than DMI, ESB and VSS. Fig.5 shows comparison of the beampatterns with the compound interferences(the third point of FH for example). Combine with Tab.1, it can be observed that the wide-band jamming can be suppressed by all algorithms, but the fast follower jamming can be only suppressed by VSS and CTMV. Furthermore, the nulling of CTMV is deeper than VSS. Therefore, CTMV has a better performance than DMI, ESB and VSS with the compound interferences in FH communication system.

Tab.2 Comparison of different algorithms with the compound interferences

Gain/dB	DMI	ESB	VSS	CTMV	Optimum
$F(\theta_1)$	-89.0	-47.8	-93.8	-75.0	-134.6
$F(\theta_2)$	-29.7	0	-43.0	-96.6	-90.6
Output SINR/dB	-0.6	-42.2	7.3	8.5	8.7

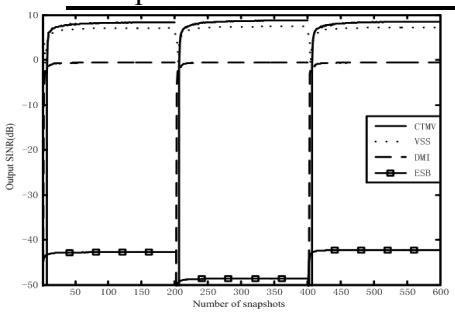

Fig.4 Output SINR versus number of snapshots with the compound interferences

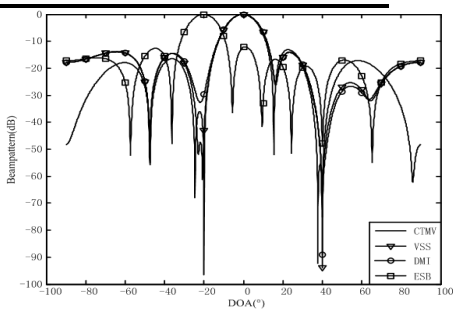

Fig.5 Comparison of the beam-pattern with the compound interferences

Conclusion

A communication scheme by combination of CTMV with FH technique for arbitrary array is proposed in this paper. Theoretical analysis and simulation results have been presented to demonstrate the wide-band jamming and fast follower jamming can be effective suppressed by

CTMV for arbitrary array in FH communication system. Furthermore, the scheme has a fast convergence speed. So it is suitable for FH communication and it can provide a reference for military FH communication, such as satellite FH communication and VHF FH communication. However the steer vector of desired signal always mismatch in the practice, which needs further research.

Keywords: Compressed Sensing; Fabric Image; Spare Representation; Sub-sampling

Abstract. Amount of data in collecting data of fabric image in the textile industry put forward a new challenge to sensor end. Compressed Sensing(CS) breaks limit of conventional Shannon's sampling theorem, so we can reconstruct a signal in Sub- sampling rate. In addition, theoretical analysis tells us that collecting the fabric image data by CS method have a better advantage than collecting the general image data. Having reconstructed three fabric images and one general image by CS method, we can easily find that the former have a high quality of reconstruction.

Introduction

Image signal is gradually favored by people owing to having rich information. As a key step to achieve textile machinery automation, collecting large amounts of image data is necessary. According to Shannon Theorem, to accurately reconstruct a signal, sampling rate must be 2 times higher than maximum frequency of the signal itself [1]. Image signal with high frequency will inevitably lead to sharp increasing in collecting data, and this must pose a severe challenge to the sensor which usually have a low operation rate.

In recent years, Compressed Sensing theorized by Candes, Tao and Donobo points out that sparse signal in a transform domain can be accurately or approximately reconstructed by a Sub-sampling rate which is lower than the Shannon sampling rate [2]. This theory has been widely used in Imaging, Sensor networks the, MRI, astronomy, and other fields, such as single-pixel camera made in Stanford University, magnetic resonance imaging, analog-digital converters.

CS requires signal sparsely in a transform domain, and CS sampling rate is negatively correlated with sparsity, fabric image should be lower CS sampling rate than usual because of it's higher sparsity [3]. we have a MATLAB text, and the result shows it works.

Compressed sensing analysis

Let's look at an intuitive example.Signal f has k nonzero values in Fig.1(here k = 2, f called k-sparse). We use a set of waveforms signals to measure f, in other words,we get five measurements through inner product between signal f and five waveforms signals according to the Eq.1:

$$y = \phi f \tag{1}$$

Above, ϕ is an matrix($M<N$,here $M= 5$, $N= 15$), f is an N-dimensional vector, y is a M-dimensional vector, any 2k columns are linearly independent, then the k-sparse vector f can be uniquely reconstructed. It is easy to know the number of measurements is less than the length of the signal itself, this may be the essence of CS [4].

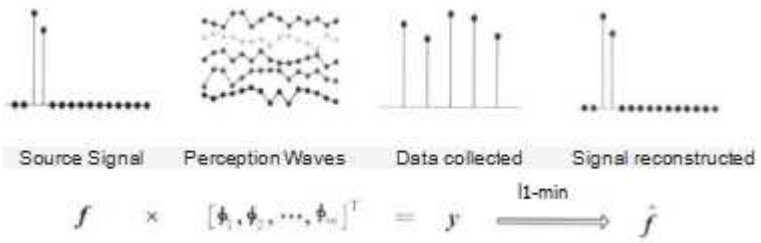

Fig.1. CS sampling mechanism flowchart

Spare representation. Image signal itself is hardly sparse, yet it has a high sparsity in a transform domain which can represent image signal features. CS asks signal being sparse in a transform domain, in other words, only few basis vectors can fully describe the signal. An N-length time signal can be described as follows:

$$X = \Psi S \tag{2}$$

Among above, each row of matrix Ψ called transformation matrix is the coordinate vector of this transform domain, and S is the coordinate value of signal in transform domain. Some transformation is often used such as DCT, DWT, DFT and so on.

Encoding measurement. Measurement matrix Φ is M x N(M<N), signal X is projected onto a set vectors based on each row in Φ. Assuming measurements is Y, which is presented as Eq. 3, Θ called sensing matrix, we can know:

$$Y = \Phi X = \Phi \Psi S = \Theta S \tag{3}$$

Decoding reconstruction. To reconstruct the signal exactly,matrix Θ must satisfy the Restricted Isometry Property (RIP) [5]. The main methods include Basis Pursuit and Greedy Algorithm [6], such as minimum 1-norm,orthogonal matching pursuit. Brief introduction to Minimum 1-norm as Fig.2, OMP introduction as Fig.3, we can easily get it.

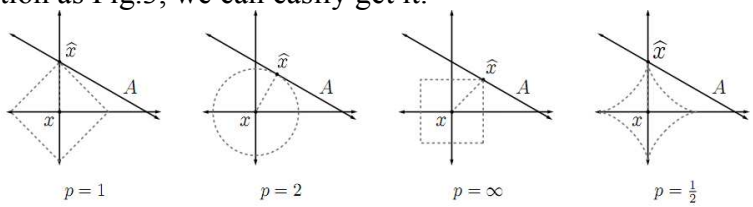

Fig.2. Best approximation of a point inby a one-dimensional subspace using the l_p norms for p = 1, 2, … and for the quasinorm with p = 1/2

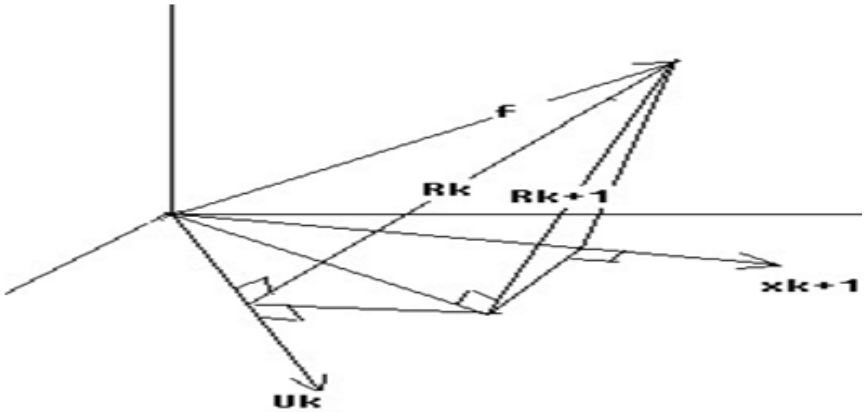

Fig.3. Fast approximation of f by combination of Component in subspace U_k and Projection in vector X_{k+1} which is independent on U_k

Test analysis

Here we have two experiments using DCT, Gaussian matrix, OMP algorithm, three fabric images and lena image. one is comparison of Nyquist method and CS method at same sampling rate, the other is comparison of the usual image and the fabric image by using CS method.

Test.1. Comparison of Nyquist and CS. We have a BROKEN END image reconstructed. In Fig.4, image above is obtained by Nyquist method, and image below is obtained by CS method .The PSNR of former is 34.6, however the latter is 41.

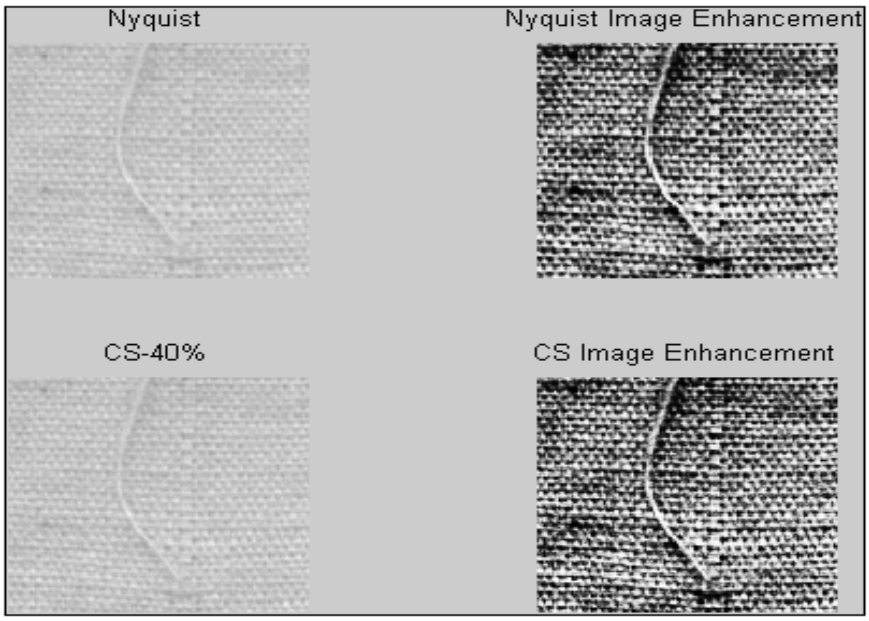

Fig.4. Comparison of Nyquist method and CS method at 40% sampling rate

Test.2. Comparison of usual image and fabric image. In Fig.5, (c)~(d) are fabric images whose left is source image, the other is reconstructed image,and (a) is a usual image. (e) is the Relative Error of each reconstructed image at different sampling rate, and (f) shows their PSNR .

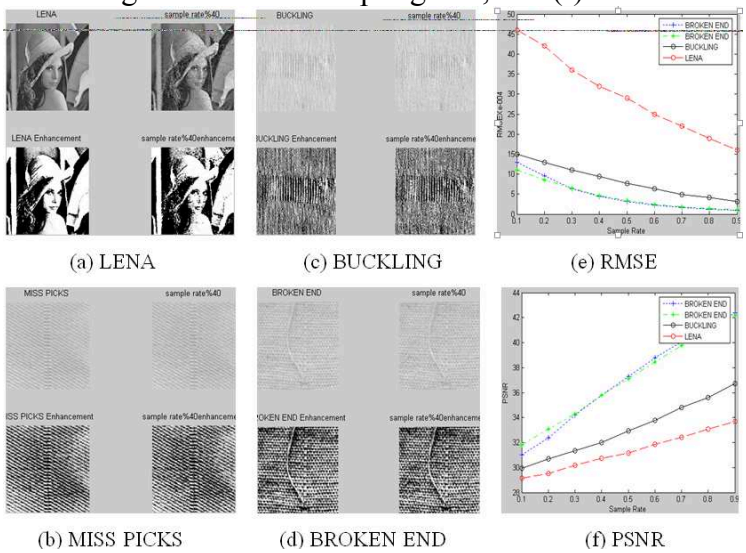

Fig.5. Fabric image comparison with usual image by CS at different sampling rate

From Fig.4 we can get a perfect image at a 40% Nyquist sampling rate. Fig.5 shows fabric image's PSNR is higher than usual image's, in other word, we can get the same level by reconstructing a fabric image at a lower sampling rate than reconstructing a usual image. In fact, the sparsity depends on the basis's selection.

Conclusion

We can not only reconstruct a signal accurately in Sub-sampling rate by CS, but also we can use fewer samples to reconstruct **f**abric image. In other word, it not only eases the contradiction between limited sensor computing speed and amount of data collected, but also breaks network bandwidth restriction. It is a great significant in terms of automated inspection of textile enterprise, such as reducing costs of sensor end, collecting more information under the same bandwidth.

Adaptive Equalization with Variable Step Size Algorithm Based on Gradient for HF Channel

Fang-Fang HAN[a], Zi-Hao LIN[b]

Urumqi Station of the State Radio Monitoring Center, Xinjiang Urumqi, China

[a]email:hanfangfang0993@163.com, [b]email:lin-zihao@163.com

Keywords: Adaptive Equalization; HF Channel; Variable Step Size; Iterative Gradient

Abstract. To further improve the performance of adaptive equalization in HF channel, a new variable step size algorithm is proposed based on the iterative gradient. The step size is set to a vector according to the weights of the equalizer, and it can vary with the iterative gradient during the equalization process. The algorithm overcomes the traditional variable step size with the constant scale for all the weights of the equalizer, thus it can obtain faster convergence rate and lower steady state error in HF channel. In the complex channel condition, the algorithm proposed in this paper can avoid the local minimum point of the objective function to obtain the global convergence performance. Simulation result shows the effectiveness in the Watterson channel model.

Introduction

The HF communication is very suitable for the middle or long distance communication [1]. The signal may include amount of inter-symbol interference (ISI) at the receiver due to the multi-path transmission, decline and time varying of the HF channel. Adaptive equalization is an effective technology to track and compensate the channel variation, which can eliminate the ISI to improve the communication quality [2]. Linear transversal equalizer with the gradient descent algorithm based on LMS criterion is simple and has the low computational complexity [3], so it is widely used in HF channel equalization. Adaptive equalization with variable step size is a compromise between large and small step size to obtain better performance of the equalization algorithm [4]. The traditional variable step size algorithm often use a constant scale for all weights of the equalizer, which use a step size decreased gradually during the iterative process. However the weights of the equalizer are not significant as the same to improve the equalization performance. Hereby, a new variable step size equalization algorithm is designed according to the iterative gradient, in which the step size is a vector but a constant value, and the variation of the step size is different for each weight of the equalizer. Therefore the equalizer can faster to convergence to the global minimum point of the objective function and obtains better performance. The simulation adopted the Watterson channel model and the results show the effectiveness of the algorithm proposed in this paper.

The HF Channel Model

The HF channel is a random parameters channel, and the characteristics vary with the time. The shortwave frequency has two transmission manners, one is shortwave ground wave transmission, and the other is shortwave space wave transmission. The shortwave space wave transmission manner implements the long distance communication, which the distance can spread from thousands to hundreds thousands meters. As a result, study on the equalization algorithm in HF channel to eliminate the ISI at the receiver is important. The characteristics of HF channel can be described by some parameters, the number of the multi-path, the time delay and the Doppler frequency shift. The signal transmitted through HF channel, the signal may reach to the receiver by different path, which is the multi-path transmission. Multi-path transmission results in frequency selective decline, and then there is aberrance in the waveform of the signal, which is the multi-path effect. Watterson model is recommended by CCIR [5], which can describe the HF channel

characteristics accuracy. The time varying frequency response function of Watterson model is given by

$$H(f,t)=\sum_{i=1}^{n}\exp\left(-j2\pi\tau_i f\right)G_i(t) \tag{1}$$

where i is the order of the multi-path, n is the total number of the multi-path. τ_i is the time delay of the i-th in the transmission path. $G_i(t)$ is the complex path gain function, which is a complex Gaussian function with independent Rayleigh distribution amplitude and uniform distribution phase. Based on the model of HF channel, the received signal can be given by

$$r_k=\sum_{i=0}^{g}s_{k-i}y_{ki}+n_k \tag{2}$$

where $\{n_k\}$ is the complex Gaussian noise with zero mean, $\{s_k\}$ is the send signal, $\{y_{ki}\}$ is the tap gain of the channel. The HF channel proposed by CCIR has two transmission paths, and the parameters of the channel for expressing the channel performance are shown in Tab.1.

Tab.1 The parameters of the HF channel

	Good condition	Moderate condition	Poor condition
Doppler shift	0.1 Hz	0.5Hz	1Hz
Time delay	0.5 ms	1 ms	2 ms

LMS Adaptive Equalization

In HF channel adaptive equalization algorithm, LMS and RLS is two main algorithms. Due to the RLS algorithm needs to calculate the inverse matrix of the input signal of the equalizer, which has burden computational complexity. Compared with RLS algorithm, LMS algorithm has lower computational complexity, and then LMS adaptive equalization algorithm is more suitable for the HF channel. LMS algorithm is educed from Wigner filter theory, which taken the mean square error as the objective function based on the MMSE to obtain the optimized solution. That is, the weights of the filter can be updated to obtain the minimum error between the output signal and the desired output signal. The adaptive equalization system is shown as Fig.1.

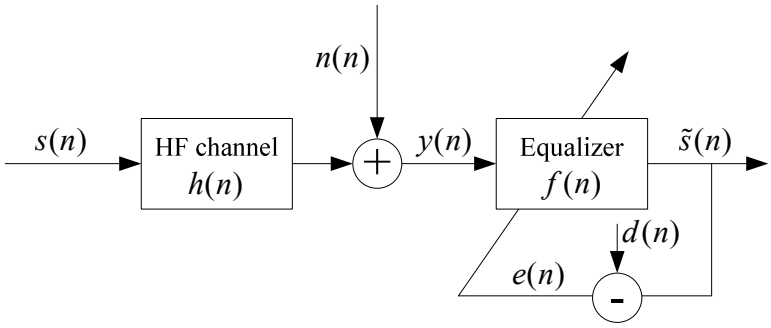

Fig.1 The basic adaptive equalization system

where $s(n)$ is the send signal, $h(n)$ is the HF channel response function, $f(n)$ is the linear transversal equalizer, $n(n)$ is the Gaussian noise. The objective function of LMS algorithm can be given by the output signal $\tilde{s}(n)$ and the desired output signal $d(n)$ as follow

$$J(n)=\frac{1}{2}E\left[d(n)-\tilde{s}(n)\right]^2 \tag{3}$$

LMS algorithm use the time mean instead of the expectation, so the objective function can be given by

$$J(n)=\frac{1}{2}\left[d(n)-\tilde{s}(n)\right]^2 \tag{4}$$

According to the gradient descent algorithm, the equalizer updating by

$$f(n+1) = f(n) - \mu \nabla J(n) \tag{5}$$

The output signal $\tilde{s}(n)$ is obtained by $y(n)$ passing through the equalizer $f(n)$ and can be given by

$$\tilde{s}(n) = f^H(n) y(n) \tag{6}$$

Then the objective function of LMS can be rewritten as follow

$$J(n) = \frac{1}{2}\left[d(n) - f^H(n) y(n) \right] \tag{7}$$

Based on Eq.7, $\nabla J(n)$ can be given by

$$\nabla J(n) = \frac{\partial J(n)}{\partial f(n)} = -\frac{1}{2}\left[d(n) - f^H(n) y(n) \right] y^*(n) \tag{8}$$

Let the error $e(n)$ is

$$e(n) = \frac{1}{2}\left[d(n) - f^H(n) y(n) \right] \tag{9}$$

The updating formula of the equalizer can be given by

$$f(n+1) = f(n) + \mu e(n) y^*(n) \tag{10}$$

where μ is the step size which control the convergence rate and convergence precision of the adaptive equalization algorithm.

Variable Step Size Algorithm

The parameter μ called step size has important influence on the performance of LMS algorithm. The larger step size can obtain faster convergence rate but bigger steady state error, and the smaller step size can obtain less steady state error but slower convergence rate. Variable step size LMS algorithm is a comprise between larger and smaller step size, and the traditional variable step size use the larger step size to speed up the convergence rate, and the step size decrease gradually during the iterative process to become smaller and smaller, and then the convergence precision is improved. However the step size is same for all weights of the equalizer, even for the variable step size algorithm, the step size is still same for all weights of the equalizer at the current iterative times. The weights of the equalizer provide different action to approach the inverse of the channel, some weights is redundant fully. Therefore the same step size for all weights of the equalizer is not an ideal method to further improve the performance of the equalization. Let the step size is a vector with the length N which is the length of the equalizer, according to the Eq.10 can give a relationship between the equalizer and the step size vector as follow

$$f(n) = f(n-1) + \mu(n) e(n-1) y^*(n-1) \tag{11}$$

Then the partial derivative of $f(n)$ to $\mu(n)$ is given by

$$\frac{\partial f(n)}{\partial \mu(n)} = e(n-1) y^*(n-1) \tag{12}$$

According to inner product operator, the partial derivative of $J(n)$ to $\mu(n)$ is given by

$$\frac{\partial J(n)}{\partial \mu(n)} = \left\langle \frac{\partial J(n)}{\partial f(n)}, \frac{\partial f(n)}{\partial \mu(n)} \right\rangle \tag{13}$$

Define the inner product operator of two vectors is computed by

$$\left\langle \frac{\partial J(n)}{\partial f(n)}, \frac{\partial f(n)}{\partial \mu(n)} \right\rangle = tr\left[\frac{\partial J(n)}{\partial f(n)} \times \frac{\partial f(n)}{\partial \mu(n)} \right] \tag{14}$$

Then the ideal step size $\mu(n)$ to minimize objective function can be updated by

$$\mu(n) = \mu(n-1) + \lambda \frac{\partial J(n)}{\partial \mu(n)} \tag{15}$$

The variable step size algorithm according to Eq.15 can drive the objective function to the global minimum point. The variable step size vector has different values for different weights of the equalizer during the iterative process.

Computer Simulations

The single carrier communication system with bit rate 2400bit/s is adopted in the simulations, and the send signal is modulated by 8-PSK. There are 56 symbols in one data packet, in which the user's data is 40 symbols and the training sequence is 16 symbols. The poor HF channel and the moderate channel are adopted to verify the effectiveness of the variable step size LMS adaptive equalization (VS-LMS). Simulation results are shown in Fig.2 and Fig.3 respectively.

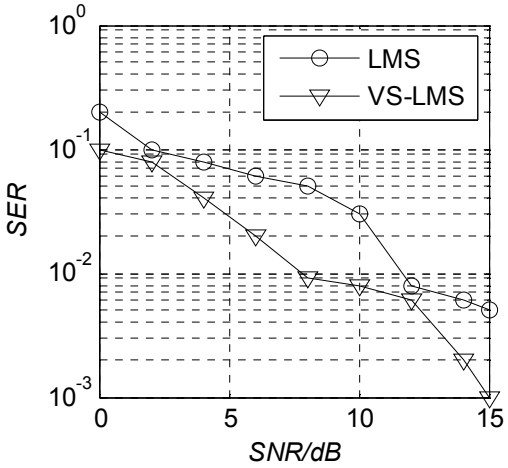

Fig.2 SER in CCIR moderate channel

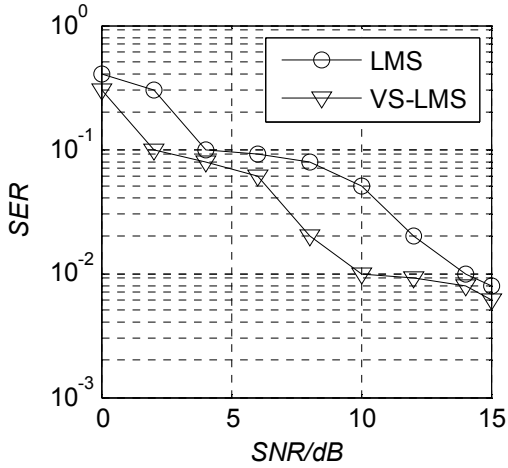

Fig.3 SER in CCIR poor channel

The results in Fig.2 and Fig.3 show VS-LMS can obtain lower SER both in the CCIR moderate and the CCIR poor channel, which proved the effectiveness of the variable step size equalization algorithm in this paper.

Conclusion

This work proposed a new variable step size adaptive equalization algorithm, in which the step size is a vector rather than a constant value. The step size is updated according to the iterative gradient based on the MMSE criterion, and it can drive the objective function convergence to the global minimum point. The simulation results show that, VS-LMS adaptive equalization can improve the performance in HF channel.

Joint Estimation of Doppler and Time Delay of Wideband Echoes for LFM Pulse Radar Based on Fractional Correlation in impulse noise environment

Li LI[1, a]

[1] Information Engineering College, Dalian University, Dalian 116622, China

[a]email: ffsimple@163.com

Keywords: fractional correlation; fractional lower order statistics;LFM Pulse signal, impulse noise

Abstract. A new method to estimate the Doppler and multipath time delay is presented in impulse noise environment. First, the Doppler is estimated by energy cumulation of multipath component based on fractional lower-order -frational correlation transform. Then, an order-reduced signal is reconstructed combining the Doppler with the prior knowledge of the transmitted signal, and the echoes signal is converted to many single-frequency signals. Finally, the multipath time delay is obtained by the fractional lower-order power spectrum method. The method is adapted for low SNR noise, can restrain the affection of the cross-items, and has a high time-delay estimation resolution. Some computer simulations are given in this paper and the results show that the new method is valid.

Introduction

At present, parameter estimation of the Doppler and time delay for LFM pulse radar echoes has received much research attention [1-2]. The broadband signals are frequently used in sonar and radar systems because of its good performance in both Doppler frequency and time delay estimation. In wideband sonar and radar systems, the echo from a wideband signal often contains a Doppler stretch (DS), not Doppler shift only, which results of difficulty in the parameters estimation [3-5]. Furthermore, in most parameter estimation methods for array signal processing, additive noise is assumed to be Gaussian, which has finite second-order statistics[7]. In some scenarios, it is inappropriate to model the noise as Gaussian noise. Therefore, this paper develops a new wideband signal model in impulsive noise.

The application of the fractional Fourier analysis in different areas has continuously increased during the last years. Fractional power spectra, which are the squared moduli of the fractional Fourier transform (FT), can be expressed in terms of the fractional correlation function. It is now a popular tool in optics and signal processing. In summary, this paper proposes a novel method, combining the fractional lower order statistics and fractional correlation, to suppress the impulse noise and estimate parameters.

This paper is organized as follows. Section Ⅱ presents a signal model in impulsive noise. In section Ⅲ, the analysis on the fractional correlation based on the fractional lower order statistics (FLOS-FC) is presented. In section Ⅳ, Doppler stretch and time delay are estimated by searching the peak of FLOSFC. In section Ⅴ, the performance of the proposed method is studied through extensive numerical simulations. Finally, conclusions are drawn in section Ⅵ.

The Proposed Signal Model

In radar or a sonar system, the received signal, in comparision with the transmitted waveform, often contains both time delay (TD) and Doppler stretch (DS). Let $x(t)$ be the transmitted signal having a constant propagation velocity. For improving the ability of anti-interference, transmitted signal is chirp signal as $x(t) = A\exp\left(j2\pi\left(f_0 t + \mu_0 t^2/2\right)\right)$ where A is the signal amplitude, f_0 is the

starting frequency, and μ_0 is the chirp rate. In wideband radar system, the received signal, in comparison with the transmitted waveform, contains both time delay and Doppler stretch. The echo $x_r(t)$ can be expressed as

$$r(t)=\sum_{l=1}^{L}\beta_l x\left(a_l(t-\tau_l)\right)+w(t) \tag{1}$$

where β_l denotes the complex constant accounting for the reflection of the l th multipath component, a_l and τ_l denote Doppler stretch factor (DS) and time delay (TD) of the l th multipath component, respectively. L is the number of multiple paths. The noise $w(t)$ is a sequence of i.i.d isotropic complex $S\alpha S$ random variable with $1<\alpha\le 2$.

Theory of Parameter Estimation based on the Fractional correlation based on the Fractional lower-order statistics

Fractional order signal processing is becoming an active research area in recent years, due to the non-stationary and non-Gaussian model in signal processing. This paper combines the fractional lower order statistics and fractional correlation[8] for suppressing the impulse noise and estimating parameters.

Fractional correlation function based on the fractional lower order statistics (FLOS-FC) $\hat{R}_{ss}^{(p)}(\rho,\varsigma)$ of the signal $s(t)$ is defined by

$$\hat{R}_{ss}^{(p)}(\rho,\varsigma)=\lim_{T\to\infty}\frac{1}{2T}\int_{-T}^{+T}R_{ss}^{(p)}(t+\varsigma,t)\exp(jt\varsigma\cot\rho)\,dt \tag{2}$$

where p is the order of the fractional lower order, and $1<p<\alpha\le 2$. $R_{ss}^{(p)}(t+\varsigma,t)=E\left\{s(t+\varsigma)[s(t)]^{<p-1>}\right\}$ denotes the fractional lower order correlation of the signal $s(t)$.

Joint Parameter Estimation Based on FLOS-FC

According to (1), we can obtain as

$$\begin{aligned}\hat{R}_r(\rho,\varsigma)&=\lim_{T\to\infty}\frac{1}{2T}\int_{-T}^{+T}r(t+\varsigma)r^*(t)\exp(jt\varsigma\cot\rho)\,dt\\&=\sum_{l=1}^{L}\lim_{T\to\infty}\frac{1}{2T}\int_{-T}^{+T}|\beta_l|^2\exp\left(j\left(2\pi\mu_0a_l^2+\cot\rho\right)t\varsigma\right)\exp\left(j2\pi\left(\left(f_0a_l-\mu_0a_l^2\tau_l\right)\varsigma+\mu_0a_l^2\varsigma^2/2\right)\right)dt+\hat{R}_{rw}(\rho,\varsigma)\end{aligned} \tag{3}$$

where $\hat{R}_{rw}(\rho,\varsigma)$ is treated as a random interference.

When $\cot\rho_l=-2\pi\mu_0a_l^2$, $\hat{R}_r(\rho_l,\varsigma)$ has the best energy-concentrated property. Therefore, we can obtain the estimator of Doppler stretch as

$$a_l=\sqrt{-\cot\alpha_{ql}/(2\pi\mu_{q0})} \tag{4}$$

Next, combining the estimator of Doppler stretch with the prior knowledge of the transmitted signal, an order-reduced signal is reconstructed as

$$g(t)=\exp\left(-j2\pi\left(\mu_0a_l^2/2\right)t^2\right) \tag{5}$$

According to the order-reduced function and the echo signal, we can obtain as

$$z(t)=r(t)\cdot g(t) \tag{6}$$

From (14),we find that the echoes signal is converted to many single-frequency signals. Finally, the multipath time delay is obtained by the dechirping method.

Assumed $R_z^{(p)}(t)$ as the fractional autocorrelation function of $z(t)$ and $\tilde{R}_z^{(p)}(u)$ as the Fourier transform of $R_z^{(p)}(t)$. So, we can obtain

$$u_l = \arg\max_u \left\{ \tilde{R}_z^p(u) \right\} \tag{7}$$

According to (14) and (15)，we can obtain the estimator of time delay as

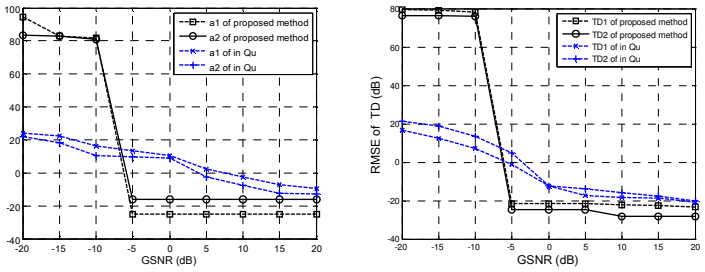
$$\tau_l = \left(f_0 a_l - u_l \right) / \left(\mu_0 a_l^2 \right) \tag{8}$$

Test results

We performed two types of simulation experiments to assess the relative performance of the proposed method under $\alpha-$stable noise and Gaussian noise conditions respectively. In order to study the robustness of the propose method, complex isotropic symmetric $\alpha-$stable $(S\alpha S)$ noise [7] model is considered. We describe the signal-to-noise condition of $S\alpha S$ using the generalized signal-noise-ratio $\left(\text{GSNR} = 10\lg(\sigma_s^2/\gamma)\right)$, where, σ_s^2 is the signal power .

In the following simulation experiments, the number of multipath is $L=2$, and Doppler stretch and time delay are $a_1 = 0.9$, $\tau_1 = 20/fs$, $a_2 = 1.1$, $\tau_2 = 100/fs$ respectively, where the sampling frequency f_s is 1MHz The number of snapshots is 1000. The number of Monte Carlo iterations is 500 in all simulations. We considered the influence of the fractional lower order moment p and the GSNR to the performance of the proposed method.

Simulation 1: Generalized signal-noise-ratio GSNR



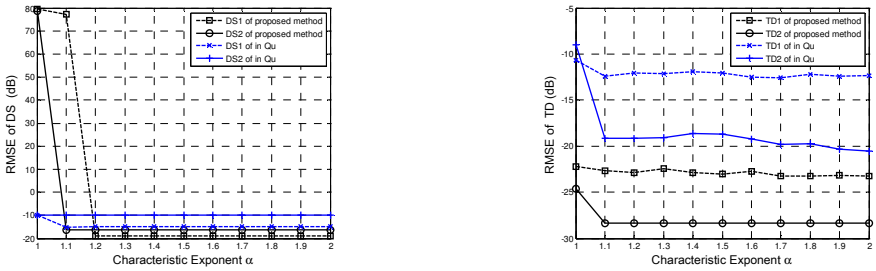
(a) (b)

Fig.1 Root mean square error versus GSNR

In this simulation, the noise is modeled as α-stable noise with $\alpha = 1.4$. Fig.1 (a)-(d) show the RMSE of the three algorithms for various values of GSNR when $p = 1.3$. From Fig.1, we can find that the estimation accuracy of the proposed method is higher than that of the method in the method of Qu.

Simulation 2: Characteristic exponent α

In this simulation, the generalized signal to noise ratio is set as GSNR=15dB, and the fractional lower-order moment is set as $p = 1.3$. Fig.2 shows the RMSE of the two algorithms for various values of characteristic exponent α.



(a) (b)

Fig.2 Root mean square error as a function of the characteristic exponent α

From Fig.2, we find that FLOS-FC algorithm shows a significant performance improvement over the method in [13] in term of RMSE for values of α in the range (1, 2) in impulsive noise environments modeled under the stable law.

Conclusion

In this paper, we proposed a novel method for estimating unknown targets parameters in impulse noise environment. In wideband sonar and radar systems, the echo from a wideband signal often contains a Doppler stretch (DS), not Doppler shift only, which results of difficulty in the parameters estimation. For the determination of the range and the relative velocity of the target, the accurate estimation of these parameters is crucial. Furthermore, the echo signal may be corrupted by the non-Gaussian noise. The conventional algorithms and signal model degenerate severely in this case. The Alpha-stable distribution model is an ideal mathematical model for non-Gaussian impulsive noise. Thus, this paper proposes a novel method that combines the fractional lower order statistics and fractional correlation, for suppressing the impulse noise and estimating parameters in the impulse noise environment. First, the Doppler is estimated by energy cumulation of multipath component based on fractional correlation transform. Then, an order-reduced signal is reconstructed combining the Doppler with the prior knowledge of the transmitted signal, and the echoes signal is converted to many single-frequency signals. Finally, the multipath time delay is obtained by the dechirping method. Simulation results demonstrate that the proposed method still has good performance when poor GSNR condition exists.

Keywords: fractional correlation; fractional lower order statistics; bistatic MIMO radar; α-stable distribution

Abstract. This paper takes the α-stable distribution as the noise model and works on the parameter estimation problem of bistatic Multiple-Input Multiple-Output (MIMO) radar system in the impulsive noise environment.This paper presents a signal model and a novel method for parameter estimation in bistatic MIMO radar system in the impulsive noise environment. Firstly, a signal array model is constructed based on the α-stable distribution model. Secondly, Doppler parameters are jointly estimated by searching the optimal rotation angle to meet concentrated-energy of the FLOS-FC. Furthermore, two algorithms are presented for the estimation of DODs and DOAs, including based on FLOS-MUSIC algorithm and FLOS-ESPRIT algorithm. Simulation results are presented to verity the effectiveness of the proposed method.

Introduction

Multiple-Input Multiple-Output (MIMO) system has attracted more and more attention for its ability to enhance system performance [1-6]. A MIMO radar system consists of both transmit and receive sensors, with the transmit sensors having the ability to transmit orthogonal waveforms.

The multi-target parameter estimation and localization is one of the most important aspects in bistatic MIMO radar. Most existing algorithms are divided into two categories. One ignores Doppler frequency and only estimated DOA and DOD as shown in [1-3]. The other estimates not only DOA and DOD but also time-invariant Doppler frequency as shown in [4-6]. The receiver signal expression shows that it has 3-Dimension array model characteristics. Three parameters are jointly estimated from three matrices obtained from low-rank decomposition. It is assumed that the Doppler frequency was time-invariant. In fact, the received signals contain time-variant Doppler frequency. In this case, these existing methods can not effectively solve this problem and provide an optimal solution.

Furthermore, in most parameter estimation methods for array signal processing, additive noise is assumed to be Gaussian, which has finite second-order statistics. In some scenarios, it is inappropriate to model the noise as Gaussian noise. To overcome these drawbacks, this paper proposes a novel method, combining the fractional lower order statistics and fractional power spectral density, to suppress the impulse noise and estimate parameters in the bistatic MIMO radar system.

The Proposed Signal Model

We assume that there are Q closely spaced transmit antennas and N closely spaced receive antennas, and L targets, with half-wavelength space between adjacent elements used for both transmit array and receive array. The transmit antennas emit orthogonal waveforms $x_q(t)$. The received signals contain Doppler frequency with time-variant. This paper presents a signal model of bistatic MIMO radar system. In general, the received signal from the nth antenna $y_n(t)$ can be expressed in (1)

$$y_n(t)=\sum_{l=1}^{L}\sum_{q=1}^{Q}\left\{\sigma_l x_q(t)\exp\left(j2\pi\left(f_l t+\mu_l t^2/2\right)\right)A_q(\varphi_l)B_n(\theta_l)\right\}+w_n(t) \tag{1}$$

where σ_l denotes the radar cross-section. f_l and μ_l denote the initial Doppler frequency (IDF) and Doppler frequency rate (DFR). $A_q(\varphi_l)=\exp\left(j2\pi(q-1)d_t\sin\varphi_l/\lambda\right)$ is the q th element of the transmitter steering vector, and φ_l is the DOD . $B_n(\theta_l)=\exp\left(j2\pi(n-1)d_r\sin\theta_l/\lambda\right)$ is the steering vector of the n th element of the receiver, and θ_l is the DOA. The noise $w_n(t)$ is a sequence of i.i.d isotropic complex $S\alpha S$ random variable with $1<\alpha\le 2$.

Since the transmitted waves are orthogonal with each other, there are $\langle x_q, x_k\rangle=0, q\ne k$ and $\|x_q\|^2=1$, for $k=1,...,Q$ and $q=1,...,Q$. The extracted signals from the q th matched filter can be expressed as

$$y_{q,n}(t)=\sum_{l=1}^{L}\left\{\sigma_l\exp\left(j2\pi\left(f_l t+\mu_l t^2/2\right)\right)A_q(\varphi_l)B_n(\theta_l)\right\}+w_n(t),\quad 0\le t\le T \tag{2}$$

Theory of Parameter Estimation based on the PLOS-FC

Fractional correlation function based on the fractional lower order statistics (FLOS-FC) $\hat{R}_{ss}^{(p)}(\tau)$ of the signal $s(t)$ is defined by

$$\hat{R}_{ss}^{(p)}(\tau)=\lim_{T\to\infty}\frac{1}{2T}\int_{-T}^{+T}R_{ss}^{(p)}(t+\tau,t)\exp\left(jt\tau\cot\rho\right)dt \tag{3}$$

where p is fractional lower-order moment and $1<p<\alpha\le 2$. $R_{ss}^{(p)}(t+\tau,t)=E\left\{s(t+\tau)[s(t)]^{<p-1>}\right\}$ denotes the fractional lower order correlation of $s(t)$.

Joint Parameter Estimation Based on FLOS-FC

In this section, study of parameter estimation is made by taking the signal $y_{qnl}(t)$ as an example.

$$y_{qnl}(t)=\sigma_l\exp\left(j2\pi\left(f_l t+\mu_l t^2/2\right)\right)A_q(\varphi_l)B_n(\theta_l)+w_n(t) \tag{4}$$

A. Doppler frequency parameters Estimation

According to (3) and (4), the FLOS-FC of $y_{qnl}(t)$ can be written as

$$\hat{R}_{yy,qnl}^{(p)}(\tau)=\lim_{T\to\infty}\frac{1}{2T}\int_{-T}^{+T}R_{yy,qnl}^{(p)}(t+\tau,t)\exp\left(jt\tau\cot\alpha\right)dt \tag{5}$$

where $R_{yy,qnl}^{(p)}(t+\tau,t)=E\left\{y_{qnl}(t+\tau)[y_{qnl}(t)]^{<p-1>}\right\}$.

When $\cot\rho_l=-2\pi\mu_l$, $\hat{R}_{yy,qnl}^{(p)}(\tau)$ has the best energy-concentrated property. Therefore, we can obtain the following expression as

$$\begin{cases}\hat{\mu}_l=-\cot\rho_l/(2\pi)\\ \hat{f}_l=\arg\max_f\left\{\tilde{R}_{y_1}^{p}(u)\right\}\end{cases} \tag{6}$$

where $\tilde{R}_{y_1}^{(p)}(u)$ is the Fourier transform of $R_{y_1}^{(p)}(t)$,and $R_{y_1}^{(p)}(t)$ is the fractional autocorrelation function of $y_1(t)=y_{q,n,l}(t)\cdot\exp\left(-\mathrm{j}2\pi(\hat{\mu}_l/2)t^2\right)$.

B. Joint DOA and DOD estimation

In this section, the DOD and DOA are estimated by employing the FLOS-MUSIC and FLOS-ESPRIT.

According to (2) and (6), both receive subarrays $\boldsymbol{R}_1$ and $\boldsymbol{R}_2$ constructed in this paper can be expressed by

$$\boldsymbol{R}_1 = \begin{bmatrix} \boldsymbol{y}_{11} & \boldsymbol{y}_{12} & \cdots & \boldsymbol{y}_{1L} \end{bmatrix}^{\mathrm{T}} = \boldsymbol{B}\boldsymbol{G} + \boldsymbol{N}_1 \tag{7}$$

$$\boldsymbol{R}_2 = \begin{bmatrix} \boldsymbol{y}_{q1} & \boldsymbol{y}_{q2} & \cdots & \boldsymbol{y}_{qL} \end{bmatrix}^{T} = \boldsymbol{B}\boldsymbol{A}\boldsymbol{G} + \boldsymbol{N}_2, \quad q \neq 1 \tag{8}$$

where $\boldsymbol{B} = \begin{bmatrix} \boldsymbol{B}_1 & \boldsymbol{B}_2 & \cdots & \boldsymbol{B}_L \end{bmatrix}$, $\boldsymbol{B}_l = \begin{bmatrix} B_1(\varphi_l) & \cdots & B_N(\varphi_l) \end{bmatrix}^{\mathrm{T}}$, $\boldsymbol{A} = \mathrm{diag}\left\{ A_q(\varphi_1), \cdots, A_q(\varphi_L) \right\}$, $\boldsymbol{G} = \begin{bmatrix} g_1(t) & g_2(t) & \cdots & g_L(t) \end{bmatrix}^{\mathrm{T}}$, $g_l(t) = \sigma_l \exp\left(j2\pi \left(\hat{f}_l t + \hat{\mu}_l t^2 / 2 \right) \right)$, $(\ )^{\mathrm{T}}$ and $\mathrm{diag}(\bullet)$ denote transpose and diagonal matrix respectively.

Spatial spectrum of FLOS-MUSIC can be got based on the classical MUSIC algorithm, which can be expressed as $P(\theta) = \dfrac{1}{\boldsymbol{B}^{\mathrm{H}}(\theta)\boldsymbol{U}_N\boldsymbol{U}_N^{\mathrm{H}}\boldsymbol{B}(\theta)}$. Searching spectral peak of $P(\theta)$, we can get the DOA estimator θ_l.

We define $\boldsymbol{C}_{11} = \boldsymbol{R}_{R_1R_1}^{(p)} - \gamma_1 \boldsymbol{I} = \boldsymbol{B}\boldsymbol{R}_{GG}^{(p)}\boldsymbol{B}^{\mathrm{H}}$ and $\boldsymbol{C}_{12} = \boldsymbol{R}_{R_1R_2}^{(p)} - \gamma_1 \boldsymbol{Z} = \boldsymbol{B}\boldsymbol{A}\boldsymbol{R}_{GG}^{(p)}\boldsymbol{B}^{\mathrm{H}}$, where $\boldsymbol{Z}$ is showed as $\boldsymbol{Z} = \begin{bmatrix} 0 & & & 0 \\ 1 & 0 & & \\ & 1 & \cdots & \\ 0 & & 1 & 0 \end{bmatrix}$. According to $\boldsymbol{C}_{11}$ and $\boldsymbol{C}_{12}$, we can get $\boldsymbol{A} = \boldsymbol{B}^{\#}\boldsymbol{C}_{12}\boldsymbol{C}_{11}^{\#}\boldsymbol{B}$.

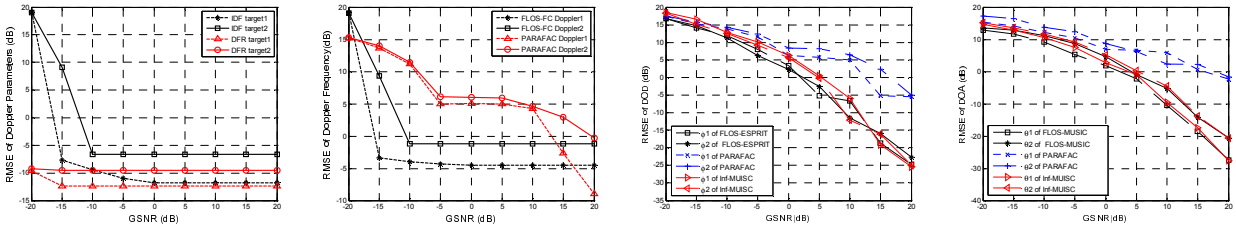
Therefore, the DOD estimator φ_l is estimated by $\varphi_l = \arcsin\left(\arg(a_l) / (q-1)\pi \right)$, where a_l is the element of the principal diagonal of matrix $\boldsymbol{A}$, $\arg(a_l)$ stands for the phase of a_l.

Test results

In order to study the robustness of the propose method, complex isotropic symmetric $\alpha-$stable $(S\alpha S)$ noise[8] model is considered. We describe the signal-to-noise condition of $S\alpha S$ using the generalized signal-to-noise $\left(\mathrm{GSNR} = 10\lg(\sigma_s^2 / \gamma) \right)$, where, σ_s^2 is the signal power.

The considered bistatic MIMO radar is composed of $Q = 4$ transmit antennas and $N = 6$ receive antennas. Supposed the target locates at the positions $(\varphi_1, \theta_1) = (30°, 20°)$, $(\varphi_2, \theta_2) = (60°, 50°)$ and Doppler parameters are $f_1 = 8, \mu_1 = 1.2$, $f_2 = 10, \mu_2 = 2$. respectively. The number of snapshots is 1000. The number of Monte Carlo iterations is 500 in all simulations.

Simulation 1: Generalized signal-noise-ratio GSNR



(a) (b) (c) (d)

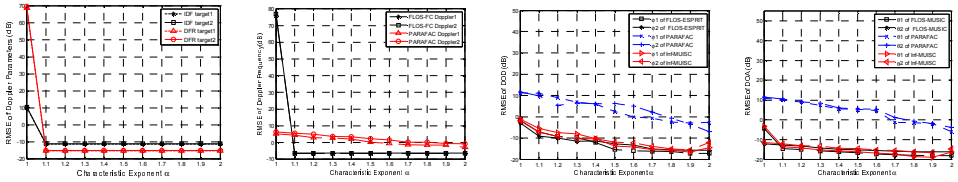
Fig.1 Root mean square error versus GSNR

In this simulation, the noise is modeled as α-stable noise with $\alpha = 1.4$ and the fractional lower-order moment is set as $p = 1.2$. Fig.1 (a) depicts the RMSE of Doppler parameters. Fig.1 (b) shows Doppler frequency estimation performance of two algorithms for various values of GSNR.

Fig.1 (c)-(d) show the RMSE of three algorithms for various values of GSNR . From Fig.1, we can find that the estimation accuracy of the proposed method is higher than those of PARAFAC method.

Simulation 2: Characteristic exponent α

In this simulation, The generalized signal to noise ratio is set as GSNR=15dB, and the fractional lower-order moment is set as $p=1.2$. Fig.2 shows the RMSE of the three algorithms for various values of characteristic exponent α.



(a) (b) (c) (d)

Fig.2 Root mean square error versus α

From Fig.2 (a)-(d), we find that the proposed algorithm shows a significant performance improvement over the PARAFAC method and Inf-MUSIC method in term of RMSE for values of α in the range $(1,2]$ in impulsive noise environments modeled under the stable law.

Conclusion

In this paper, we proposed a novel method for estimating unknown targets parameters in impulse noise environment. Firstly, we present a signal model under Alpha-stable distribution noise in bistatic MIMO radar system. Secondly, Doppler parameters are estimated by the FLOS-FC algorithm. Thirdly, two subarray models are constructed and two algorithms are presented to estimate DOD and DOA. Simulation results demonstrate that the proposed method still has good performance when poor SNR condition exists.

Keywords: Video Correction; The relation of inter-views; Multi-view video coding; View Scalability

Abstract. In order to enables the video to be displayed on a multitude of different terminals, Multi-view video coding (MVC) demands high compression rates as well as view scalability. A new the inter-view prediction structure with flexibility, MVC compatibility and view scalability is proposed. The proposed scheme first correct views. It then uses the position of the cameras and the relation of inter-views to divide all views into base view and enhancement views. Finally, the views quire by the viewers use scalable Multi-view Video Coding (SMVC). The main bitstream is the same as a H.264/AVC mono-sequence bitstream for H.264/AVC compatibility. The auxiliary bitstream come from enhancement views coding. We proposed SMVC scheme is tested with two Multi-view sequences to determine its flexibly view scalability, high coding efficiency and random access performance.

Introduction

Multi-view Video is proposed for interactive media, which mainly solves the problems of 3D interactive video performance, interactive and storage, transmission etc.. It is composed of a plurality of camera shooting from different angles to record multiple view data, which provided to the user to view selection and the scene roaming interactive ability[1] [2]. As with 2DTV, the 3DTV/FTV transmission system with the heterogeneity of network and terminal diversity. Due to its MVC data volume is much larger than the 2D video, makes the MVC in how to adapt to the network terminal degeneration, diversity, how to meet the low complexity and low delay, face greater challenges. Different users tend to use different terminals, they have different access bandwidth, different computing ability, different display capabilities. Multi-view stereo video only to the transmission mechanism more flexible to provide users with more degrees of freedom (for example, the general two-dimensional video or stereo video, a three-dimensional view of). Therefore, due to the JVT proposed Multi-view video coding [8] into view scalable coding, to meet different user needs at the same time, as far as possible to improve the coding efficiency.

At present, most of the existing MVC algorithm in a specific time and space resolution and fixed rate to get the best coding efficiency, and therefore can not be based on user terminal dynamic self-adapting coding different View number. Therefore, Lim first proposed the parallax view scalability characteristics of the support structure, and the realization of the MPEG-2 coding scheme based on [3], but the prediction structure of the program in terms of MVC, the compression efficiency is not high and are not compatible with the H.264/AVC; MIT Samuel L.Hill of the camera array shooting scalable[4], calibration but its focus on camera and display of the scalable coding; Ozbek et al. (Scalable Video Coding, SVC), and extend it to the scalable Multi-view video coding (SMVC) [5], but not on the view scalability; Yang[6] proposed a MPEG-4 compatible stereo Multi-view video coding scheme, in addition they also proposed a Multi-view video coding scheme based on wavelet, realize the time, spatial and PSNR scalability of[7], but which are not compatible with the H.264/AVC. Moreover, these methods have not considered the content correlation Multi-view video sequence with the camera placed between viewpoints and illumination and other factors varied phenomena.

In this paper, based on MVC, for Multi-view video signal sequence inter view correlation with the layout of camera and illumination and other factors varied phenomenon, given to predict the structure of a new inter viewpoint, to improve the coding efficiency while achieving scalable views, such as vertex classification can be combined with SVC together, provide a wider range of scalability. First we have the perspective correction for video sequences, the elimination of inter view image color and luminance inconsistency. Then according to the camera's position and inter view correlation effectively hold the view into basic viewpoint and the enhancement layer view, view the number of users required for scalable coding.

Video correction

Inter view image color inconsistency is a problem in urgent need to solve the Multi-view video coding in [8], the main causes of it are scene illumination, camera placement and exposure. Most of scholars, areper spective correction [9][10][11] by histogram matching, To eliminate the differences between the view image color, but there are differences between the views of brightness. Jae-Ho Hur et al [12] compensation in frequency domain, the brightness difference between the viewpoint that image macro block DC coefficients, such a treatment not only speed is larger and has achieved good results, but the difference between the color point of view is relatively large, the effect is not ideal for vision correction.

Fig.1 (a) Original images of 0^{th} and 4^{th} viewpoints in Flamenco2

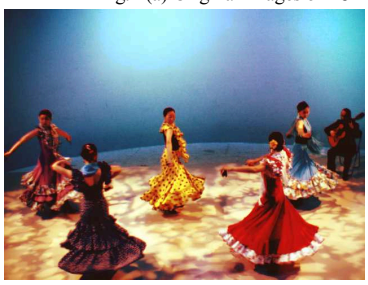

Fig.1 (b) Corrected images of 0^{th} and 4^{th} viewpoints in Flamenco2

Figure 1. The original image and the Corrected images

SMVC

MVC adopts a hierarchical B frame (Hierarchical B Picture) to realize the temporal scalability, inter view can also use a hierarchical B frame structure and a higher coding efficiency, coding delay, and is convenient for short random access to view scalability. Figure 4. shows the time hierarchical B frame inter view / prediction structure. According to the predicted sequence shown in Figure 6, each frame of video coding prediction can be adopted by the encoder reconstruction frame as the reference frame, and can easily achieve the view / temporal scalable coding. So you don't have MCTF (Motion Compensated Temporal Filtering) end reference frame inconsistency problem encoding and decoding structure.

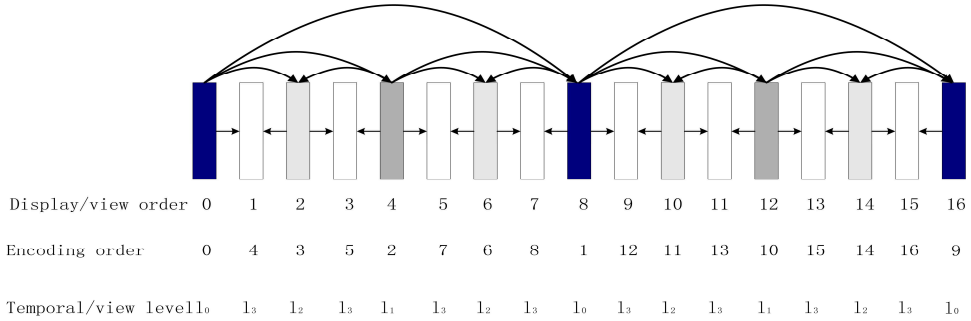

Figure 2 Hierarchical B frame inter view / prediction structure.

But such inter view prediction mode is single, it is difficult to adapt to the Multi-view video sequences with different. In the hierarchical inter view prediction structure, in order to get a better view of random access function usually lost to predict the relationship between the partial view, but such Multi-view video coding performance is low. For example, Simulcast code, using I-View code, the user can randomly access each viewpoint, however, did not use the inter view prediction,so the rate distortion performance is low. Generally speaking, when the inter view prediction structure layer is less, there will be more view video are encoded independently or only one view reference frame,disparity estimation so that the relationship between the loss of the more, random view access performance is better, but the overall coding performance is not high; with the increase in prediction of structural layers, independent encoding the video will be reduced, the overall coding performance will be improved, but the poor performance of random access.

Test results

In order to Multi-view coding and MVC to verify our proposed compatible, and flexible scalability and random access performance, we were on the two Multi-view video sequences were tested. .

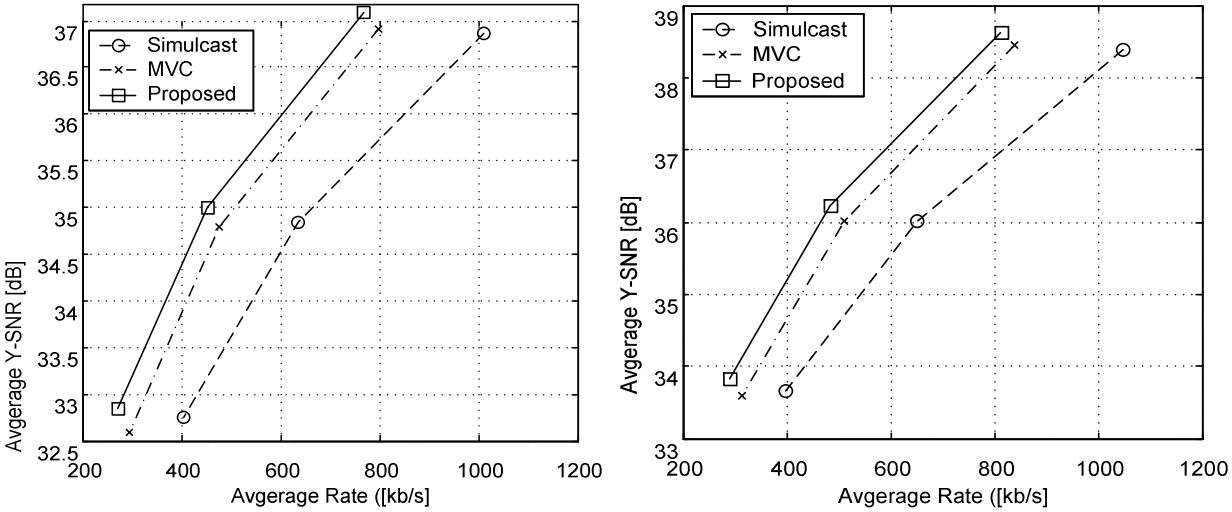

Figure 3. Rate distortion performance comparison

Figure 3. gives the best rate distortion performance comparison,Simulcast encoding the inter view prediction MVC said no, Multi-view video coding scheme is proposed by JVT. SMVC scalable coding methods for this view. On the difference in color between the sequences of Famecon2 and ballroom, through the perspective correction, the coding efficiency is improved obviously, We proposed SMVC scheme is tested with several Multi-view sequences to determine its flexibly view scalability, high coding efficiency and random access performance.

Conclusion

In this paper, based on MVC, for Multi-view video signal sequence inter view correlation with the layout of camera and illumination and other factors varied phenomenon, given to predict the structure of a new inter view, in ensuring the high rate distortion performance at the same time, improve the random access performance, we view scalability, and this view scalability can be combined with SVC, to provide a wider range of scalability. The coding, the perspective correction, and reduce the influence of the difference between colors as the coding, the view selection, and presents a reasonable inter view prediction structure, the coding efficiency is high, improve random access performance, support the view class. We will further study the view scalability in combination with SVC, to provide a wider range of scalability.

De-noising of Underwater Acoustic Weak Signals Based on Compressed Sensing Technique

Lili ZHAO, Xiaowei DAI

PLA 91550 Unit, Liaoning Dalian, China

email: 13904286205@139.com

Keywords: Compressed Sensing; Wavelet Transformation; Filter Design; Weak Signal De-noising.

Abstract. To remove the noise of weak signals detected in the underwater environment, the existing de-noising algorithms cannot perform satisfactorily. This paper aims to developing a new method to solve the problem, where the compressed sensing theory, wavelet transformation based filtering techniques and sparse signal reconstruction algorithm are employed. The simulation results show that the proposed algorithm performs favorably and has good potential to be used in some engineering applications.

Introduction

Periodic sound waves spread in water with the water pressure when the water to the surface acoustic wave propagates for time being, the joint action of this cyclical pressure, water surface tension and gravity of the original still water drives the jump-up and drop-down movement. If a laser shines on rough water surface which is excited by underwater sound field, the scattering beam bidirectional reflectance distribution function can be observed. While utilizing the optical system with a field of view to observe the surface, we can observe the entire process of the "rough" through the water surface mirror. The system receives the reflected light intensity and converted to the electrical signals of underwater sound field.

Wavelet analysis is an emerging technique over the past years, which has been rapidly developed due to its merits in data representation power and some nice properties for signal processing. Recently, wavelet transforms have been widely recognized and used in weak signal detection, feature extraction, data compression, fault diagnosis, and is playing a significant role in information technology and signal processing. Wavelet-based de-noising techniques can be currently clustered into three categories, which are presented in different forms according to the amplitude of the wavelet coefficients of the desired signal by selecting an appropriate threshold value. This way can remove effectively some high frequency noise and retain significant coefficients for approximate the original signals. As can be seen that the select of an appropriate wavelet threshold will play a key role in this approach for de-noising performance, hence so far, most studies have focused on optimizing the threshold value to achieve improved performance.

The basic idea behind the theory of compressed sensing is to find a better way to represent data with few parameters without loss of much information when the data is reconstructed [1]. A study in [2] pointed out that for noise-free signal the wavelet coefficients obtained by Mallat algorithm is sparse, that is to say, only few coefficients with significant values will be sufficient to represent signals. However, as noise presents, this sparse property of the wavelet coefficients does not hold. Therefore, the compressed sensing theory can be employed to achieve the goal for noisy reduction.

This paper considers a problem of de-noising underwater acoustic signal using wavelet compression-aware filtering method. A novel algorithm is proposed and some simulation results are reported. These primary results demonstrate that our proposed algorithm for noise removal of weak underwater acoustic signals is promising, and outperforms the wavelet-based de-noising method.

Compressed sensing theory

The compressed sensing theory is proposed by Candes and Donoho in 2006, the basic idea is non-adaptive linear projection signal acquisition, and then reconstruct the original signal by

reconstruction algorithm according to the corresponding values from the measured value [3]. It includes three aspects of the sparse representation of the signal, coding measuring coding and reconstruction algorithms. The Sparse signals represent that orthogonal projection transformation converted to vector signal group, and the vast majority of absolute value of the transform coefficients is small. The resulting is sparse or similar sparse, which can be viewed as a simple expression of the original signal. This is a priori condition of compressed sensing that the signal must be sparse representation under certain transformations. In the encoding measurement, first thing is to select a stable projection matrix. In order to ensure linearity of the signal to maintain the original structure of the signal, the isometric projection matrix must satisfy the restricted isometric property (RIP). And use the result of the original signal measured by the product of the matrix measurement to obtain a linear projection of the original signal. Finally, the original signal is reconstructed by the algorithm of the measured value and the projection matrix. The signal reconstruction process is generally converted into a minimum l_0 norm optimization problem.

One of the known measurement matrix is $\phi \in R^{M \times N} (M << N)$, as well as a signal $y \in R^N$ measured value in the measurement of linear matrix under $y \in R^M$, that is:

$$y = \phi f \tag{1}$$

Now consider the reconstruction f by signal y, apparently, because of the dimension of y is far less than the dimension of f, the above equation has infinite kinds of solutions. By theoretical proof, the signal from the measured values y, and f can be reconstructed accurately by solving the optimal l_0 norm:

$$\hat{x} = \arg\min \|x\|_0 \qquad s.t. \qquad \Phi x = y \tag{2}$$

where $\|\bullet\|_0$ is the l_0 norm of the vector, which represents the numbers of non-zero in vector x. However, the common natural signals are almost not sparse in the time domain, so that the signals need to be converted by some kinds of transformation Ψ to a sparse representation.

$$y = \Phi f = \Phi \Psi x = \tilde{\Phi} x \tag{3}$$

where $\tilde{\Phi} = \Phi \Psi$ is the $M \times N$ matrix, which was also called sensing matrix, y can be seen as the measured value of sparse signal x about the measured matrix $\tilde{\Phi}$. To reconstruct sparse signals, Candes and Tao presented and proved that sensing matrix must satisfy the constraint equally conditions. For arbitrary constants, if

$$(1-\delta_K) \| c \|_2^2 \leq \| \tilde{\Phi}_T c \|_2^2 \leq (1+\delta_K) \| c \|_2^2 \tag{4}$$

is established, which $T \subset \{1,...,N\}$, $|T| \leq K$ and $\tilde{\Phi}_T$ is the sub-matrix constituted by the column of the index T in the matrix $\tilde{\Phi}$. The signal reconstruction algorithm is the basic theory of compressed sensing. Candes and others proved that signal reconstruction problems can be solved by solving the problem of the minimum l_0 norm, but Donoho stated that the minimum l_0 norm problem solving is essentially an NP-hard problem, which usually required for conversion. Therefore, the researchers made a series of algorithms to obtain sub-optimal solutions, including the smallest l_1 norm method, match tracking series algorithm, iterative threshold method and the minimum variables analysis method [4][5].

De-nosing algorithm process steps

The wavelet filtering theory shows that the noise signal wavelet coefficients at each scale does not have sparse property. Therefore, it can be used to restore the sparse of wavelet coefficients by compressed sensing theory, in order to achieve the purpose of signal de-noising. The flow chart of the algorithm step is shown in Fig.1.

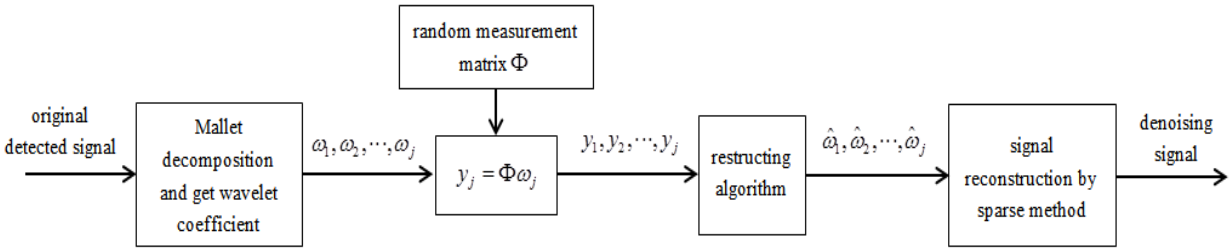

Fig.1 Underwater Acoustic Signal de-noising process steps

The random measurement matrix in the algorithm must meet the uniform uncertainty principle (UUP), that is, for any S-sparse vector x, if:

$$0.8\frac{M}{N}=\|x\|_2^2\le\|\varphi x\|_2^2\le 1.2\frac{M}{N}\|x\|_2^2 \qquad (5)$$

then the set of size S meets the UUP principle, where the perception matrix is currently used as a random matrix, such as Gaussian matrix, Bernoulli matrix, Fourier random measurement matrix and non-correlation measurement matrix [6].

Simulation results and analysis

The characteristics of the simulation processing signal of underwater acoustic signal are short time, low energy and transient. The original acquisition signal is $f(t)=s(t)+n(t)$, where $s(t)$ is the weak signal that will be extractive (as shown in Fig.2a), $n(t)$ is the signal of the system environment in the process of detection and the background noise, the signal-to-noise ratio of the detected signal $f(t)$ is set to -8.09dB (as shown in Fig.2b),which can be observed that the weak signals are submerged by noise signals[7][8].

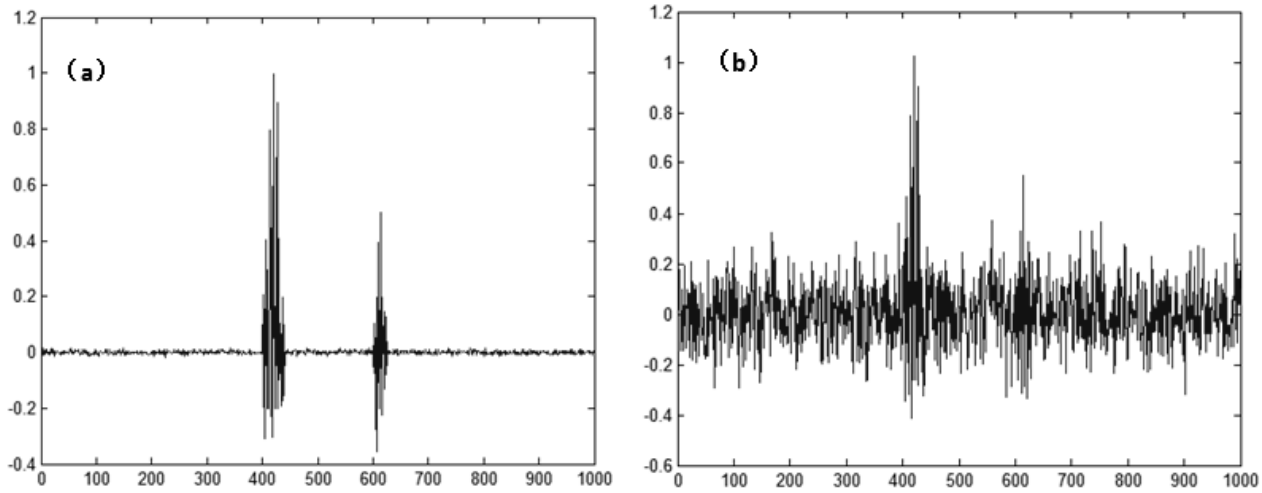

Fig.2 The original signal (a) and noise mixed signal (b)

When it has the strong noise interference, the traditional wavelet threshold algorithm can only detect a strong signal because of fixed threshold limitations, and the weak signal is cut as noise filtering (as shown in Fig.3a), the de-noising algorithm based on compressed sensing theory correctly detect the corresponding weak signals (as shown in Fig.3b).

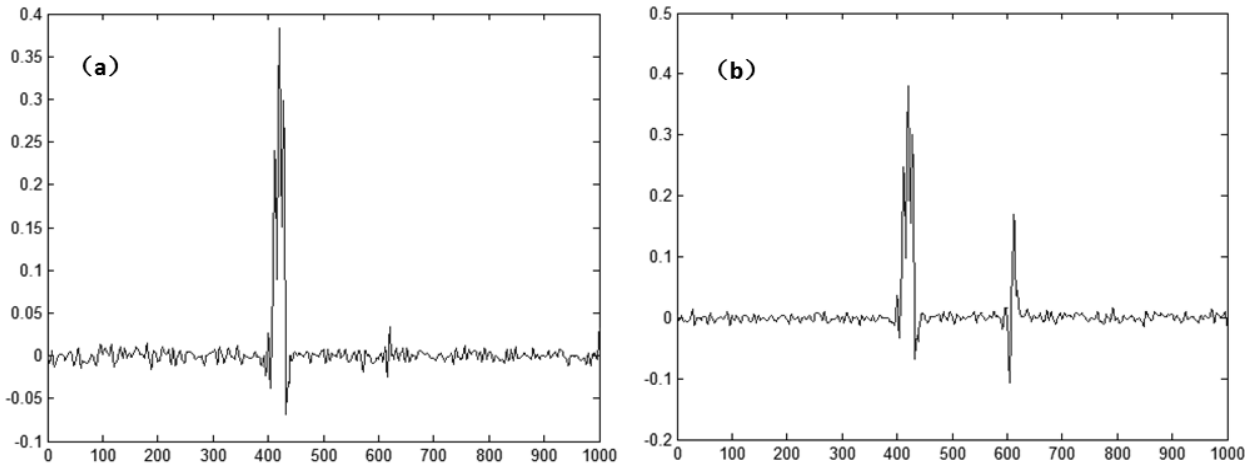

Fig. 3 The traditional wavelet de-noising (a) and compressed sensing theory based on improved effect (b)

This shows that with the deepening of decomposition scale, the wavelet coefficients of each scale only has a small number of large coefficients. When the signal has the noise, the wavelet coefficients corresponding to the noise reduced rapidly, but the wavelet coefficients of the signals are enhanced, so the sparse property of wavelet coefficients will be greatly reduced. Therefore, the methods of wavelet coefficient sparse property recovery based on compressed sensing theory can be used in weak signal detection, with the advantage of achieving the effective extraction of the useful signal and avoiding the difficult problem of threshold choice of wavelet threshold filtering.

Conclusions

This paper addresses a problem of removing weak noise from underwater acoustic signals. Our proposed algorithm is based on the well-known compressed sensing theory. A comparative study demonstrates that our proposed algorithm outperforms the wavelet based de-noising technique. Although the compression reduces the amount of information detail of the signals, it does not bring much negative effects on filtering noises.

Keywords: Uniform Circular Array; Amplitude Weighting; Beam-forming; Side-lobe Suppression

Abstract. The uniform circular planar array (UCA) has lots of advantages what linear arrays and other surface arrays don't have. However, because of its limitations, such as the high side-lobe level and low zero depth, the application on controlling array space direction by beam forming has been limited. Considering the characteristics of UCA, the receiving UCA's signal model is established in this paper. The influence factors of UCA's beam will be found out on the basis of theoretical derivation. A new method, that can improve the performance of the UCA beam directivity by amplitude weighting, is proposed in this paper. The theoretical derivation results and simulation results improved that the method could have a better ability in side-lobe suppression, and the new method could make the UCA to have a good application prospect.

Introduction

In the fields of the modern wireless communication system, radar detection and navigation guidance, more and more UCAs appear due to their characteristics such as less elements then planar array antenna wind, easier to conform with carriers and its 360-degree angle range in azimuth [1][2]. In reference [3], the UCA is applied in wireless sensor networks and in reference [4] UCA is used for monopulse angle measurement. Beam forming technology is an important technology in array signal processing. Beam forming technology can delay and compensate the receiving signals what are from space sources, so the output of the UCA can be superposed in the same phase, and then we can get a peak on the angle of arrival (AOA) of the source. Applying the beam forming technology can also control the pointing angle of the UCA, which is the most used in phased array radar. The array directivity is an important indicator of beam synthesis technology, it determines the sensitivity of the array and the target resolution [5].Although UCA has many advantages, but there are also disadvantages such as the wider main lobe width , the higher side-lobe level and so on, what cause the UCA having a poorer directivity performance compared with uniform linear array(ULA).So it is more important to improve the directivity performance of the UCA. Weighted algorithm can effectively improve the uniform circular array directivity. A weighted algorithm of uniform circular array is systematically discussed in this paper. An improved weighted algorithm is proposedd based on the existing weighted algorithm, it is an effective method for suppressing the side-lobe, and it can effectively improve the directivity of UCA.

The Model of UCA

Uniform circular array（UCA），is an array antenna who's array elements are evenly distributed in on the circumference of a circle with a radius R. The number of the elements is M， and they are omnidirectional without cross coupling. The model is given in Fig.1.

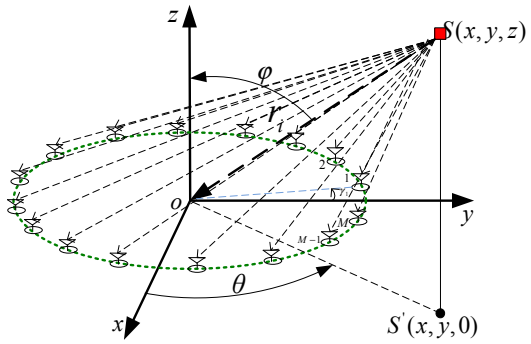

Fig.1 Uniform Circular Array Model

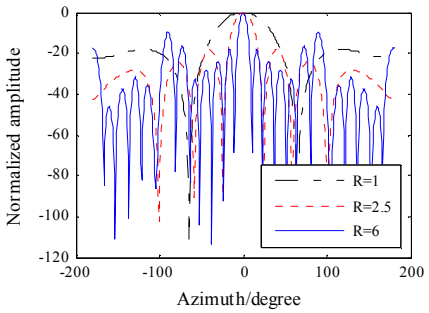

Fig.2 UCA Azimuth Pattern(M=16)

The elements of UCA in Fig.1 is considered as point elements. The far field narrowband source, s(t), spreads its energy to the UCA. We can also see the Azimuth, θ, the pitching angle φ and the source S with its incident angle (θ,φ) in Fig.1. We can set o as reference point, then the signal $s_l(t)$, which is get from the lth element of the UCA，where, $l=1,2,...,M$ (similarly hereinafter).

The direction vector of the array is an important parameter in array Analysis. Popularly, it is recorded as $\mathbf{a}$ .Hereby we give the direction vector of UCA directly as follow.

$$\mathbf{a}(\theta,\varphi)=[\exp[j\frac{2\pi R}{\lambda}\sin\varphi\cos(\theta-\gamma_1)],\exp[j\frac{2\pi R}{\lambda}\sin\varphi\cos(\theta-\gamma_2)],\\ ...,\exp[j\frac{2\pi R}{\lambda}\sin\varphi\cos(\theta-\gamma_M)]]^T \tag{1}$$

Influence Factors of UCA Pattern Performance

The width of main lobe determines the spatial resolution of the array，it is a key factor for the directivity of array. The spatial resolution of regular array is proportional with the array aperture [6]. The three UCA azimuth beam patterns is given in Fig.2. According to the simulation, we can find:

1) The width of main lobe. In Fig.2，when the radius of the UCA increasing，the width of main lobe narrows down, which appears the same regulation with regular array, such as ULA.

2) The side-lobe level. Different from the main lobe, the side-lobe level doesn't become lower when R increasing. When R is up to 2.5m from 1m，the side-lobe level becomes lower, but oppositely, when R=6, it becomes higher than the side-lobe level where the R=1,we call the unusual high side-lobe grating lobe.

To explain why the grating lobe appears and select a right R for the UCA, we quote a function from reference [1] as Eq.(2) as following

$$F_k(\theta)=\frac{M}{2\pi}j^kJ_k(\beta)\exp(jk\theta)+\frac{M}{2\pi}\sum_{i=-\infty}^{+\infty}j^{(k+iM)}J_{(k+iM)}(\beta)\exp[j(k+iM)\theta]=F_{Ek}+F_{Nk} \tag{2}$$

where， $\beta=2\pi R/\lambda$ and $J_k(\beta)$ the first class of Bessel functions of order k based on the variable β. By the nature of the first class Bessel function，we can find ,when $k>\beta$, $J_k(\beta)\approx 0$ .So, when $M>2K$,we have $|k+iM|>\beta$ and $|k|\le K$,where $K=\lfloor\beta\rfloor$. And then $F_{Nk}\to 0$, So, Eq.(2) can become as $F_k(\theta)\approx Mj^kJ_k(\beta)\exp(jk\theta)/2\pi$ .In the simulation , we had set $M=16$ and λ =3m, according to the constraint condition of $M>2K$,we can find $R_{\max}=1.2\lambda$ =3.6m, So we got a grating lobe when R=6m in the Fig.2.

Improved Symmetric Weighting method (ISWM)

To improve the directivity of the, In addition to selecting the right R, we can also array element weighted method. The formula is

$$G=\sum_{l=1}^{M} w_l g_0 \exp(-j\omega\tau_l)\ \ l=1,2,...,M \tag{3}$$

w_l can be divided into phase weighting and amplitude weighting. The phase weighting method can compensate signal phase, left the amplitude unchanged; The amplitude weighting method weights the amplitude left the phase unchanged. We can control the direction of the UCA by $w_l=\exp(j2\pi R\sin(\varphi_0)\cos(\theta_0-\gamma_l)/\lambda)$, which is the phase weighting.

To find a nice amplitude weighting method, we should consider two aspects. We must try to make the side-lobe level lower; otherwise, we shouldn't let the main-lobe much wider. The phase weighting for UCA has little influence on its side-lobe level. So, we must make the side-lobe level lower by amplitude weighting method. It is very complicated to suppress the side-lobe. Some researchers make it by changing the hardware structure of the elements [7], but there is little researcher make it by amplitude weighting method. And we can find out that the ordinary window functions, such as Hanning-window, make no use on suppressing the side-lobe level for UCA in Fig.3.

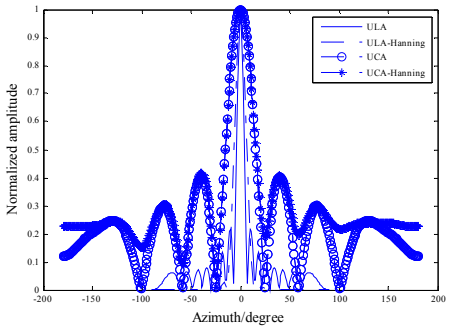

Fig.3 ULA&UCA Azimuth Pattern(M=16)

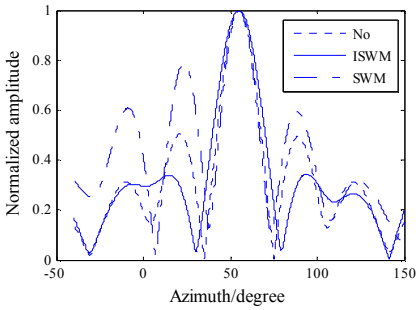

Fig.4 UCA Azimuth Pattern after ISWM

In this paper, An improved weighted algorithm is proposed for suppressing the side-lobe level of the UCA. The theoretical derivation is given as following.

1) The essential conditions of the improved amplitude weighting method

Condition 1: $w_l=w_{M+1-l}$; Condition 2: The elements position of the UCA showed in Fig.1 and $\gamma_l=[\pi+2\pi(l-1)]/M$, $l=1,2,...,M$; Condition3: $w_l^*=w_{2M_0+1-l}$, $l=1,2,...,M_0$, where, M_0 is the number of the elements in one quadrant in Fig.1.

2) The theoretical derivation

Based on the Eqs above, we can easily get the output of the UCA.

$$G(\theta,\varphi)=\frac{1}{M}\sum_{l=1}^{M} w_l \exp\left[j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta-\gamma_l)\right] \tag{4}$$

Step 1: Using condition 1 and condition 2, we can simplify the Eq. (4)

$$G(\theta,\varphi)=\frac{1}{M}\sum_{l=1}^{2M_0} w_l\left\{\exp\left[j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta-\gamma_l)\right]+\exp\left[j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta+\gamma_l)\right]\right\} \tag{5}$$

Step2: Using Condition 3 and condition 2, the Eq. (5) can be simplified as,

$$\begin{aligned}G(\theta,\varphi)=&\frac{1}{M}\sum_{l=1}^{M_0} w_l\left\{\exp\left[j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta-\gamma_l)\right]+\exp\left[j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta+\gamma_l)\right]\right\}\\&+\frac{1}{M}\sum_{l=1}^{M_0} w_l^*\left\{\exp\left[-j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta+\gamma_l)\right]+\exp\left[-j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta-\gamma_l)\right]\right\}\end{aligned} \tag{6}$$

Step3: $w_l=w_{lR}+iw_{lI}$, where, w_{lR} is real part, w_{lI} is the imaginary part. So

$$G(\theta,\varphi)=\frac{2}{M}\sum_{l=1}^{M_0}w_{lR}\left\{\cos\left[j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta-\gamma_l)\right]+\cos\left[j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta+\gamma_l)\right]\right\}$$
$$-\frac{2}{M}\sum_{l=1}^{M_0}w_{lI}\left\{\sin\left[j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta-\gamma_l)\right]+\sin\left[j\frac{2\pi R}{\lambda}\sin(\varphi)\cos(\theta+\gamma_l)\right]\right\} \quad (7)$$

3) Adaptive adjustment of the amplitude weighting

In order to satisfying condition 2，the amplitude weighting we chose should be adaptive to the searching angle. So we should adjust the amplitude weighting in ISWM.

Simulation Result and Analysis

According to the Eq.6，the complex exponential terms in the Eq.4 has been transformed to sine terms by using the three conditions; And the UCA output functions is an even function about azimuth θ, in other word, the UCA has the characteristics of the symmetry about azimuth, and we can find the symmetry of the beam pattern using ISWM obviously, through the simulation results showed in Fig.4. The simulation parameters are set as M=16, R=3.5, λ=3m , φ= 30°, θ=55°. From the simulation results by using different methods of amplitude weighting methods, we can find that the side-lobe can not be suppressed when using the SWM. But when using the methods of ISWM, which is proposed in this paper, the side-lobe was suppressed and the mainlobe was not broadened seriously. This could prove the effectiveness of the method of this paper.

Conclusion

This paper has proposed an improved method of weighting for uniform circular array, which is called ISWM. This method can suppress the side-lobe of the beam parttern effectively. With the constraint conditions of UCA aperture, the beam directivity of the UCA is improved significantly after the ISWM. The simulation results shows that the UCA ,horizontal, has the symmetry about azimuth for its beam pattern, and its amplitude weightings can be adaptive with the searching angle, so, the sidelobe can be reduced effectively, and the directivity of the UCA is improved significantly.

Acknowledgement

This paper is funded by the International Exchange Program of Harbin Engineering University for Innovation-oriented Talents Cultivation. I should express my sincere gratitude for this.

email: XiufangLiu@126.com

Keywords: Wavelet Transform; Median Filtering; Impulse noise; Telemetry

Abstract. The telemetry signal is often interfered with impulse noise, which results in difficulty in time domain and frequency domain analysis results. Hereby a new impulse noise suppression method based on wavelet transform and median filtering technique was proposed. The received signal is decomposed into detailed components and approximate components, and then the median filtering is carried on the wavelet decomposition components with vary filtering window size according to the wavelet transform scale respectively. This method can suppress the impulse noise effectively and keep the detail information of the signal from the loss at the same time. The simulation and experimental results prove the effectiveness of the method.

Introduction

In vehicle tests, the telemetry environmental parameters reflects the internal state of the aircraft in flight [1], processing and analysis of telemetry environmental parameters is an important work in the vehicle test and the results evaluation. Telemetry environmental parameters are often interfered by channel multipath and noise interference in the transmission process. The multipath transmission would induce inter-symbol interference and the adding Gauss noise may result in amplitude distortion. The receiver uses equalization or diversity technology, can generally get the original data is satisfactory. However, in the practical engineering, the noise interference by telemetry signal transmission process often exhibit impulse noise characteristics of [2], which includes short-term greatly impulse in the time domain waveform. Impulse noise interference results in the telemetry environmental parameters processing method failure, such as filtering, least square fitting, and the impulse noise [3] seriously affects the spectrum analysis in the frequency domain and the mean square error statistic in the time domain, and further affect the identification of the state in the process of aircraft reliability. Therefore, must find effective methods for impulse noise suppression in telemetry environmental parameters processing. The median filter is considered to be an effective nonlinear filtering method to eliminate the impulse noise [4], found in applications, the median filter window selecting has an important effect on the performance of impulse noise suppression. The larger median filtering window can suppress the impulse noise interference at the maximum extent, but the detail information of the received signal may loss, the smaller median filtering window can better keep the detail information of the signal, but the impulse noise suppression ability is weak. Therefore, combined with wavelet transform, this paper presents a multi-scale median filtering method, which uses the band-pass filter characteristics of the wavelet transform [5] to decompose the received signal into a series of detail components and approximate component, thus the impulse noise would distribute to each component in the signal. The median filtering window size is determined based on the wavelet decomposition components and the decomposition scale. Wavelet decomposition components finally reconstruct the original signal after median filtering. This method can effectively keep the signal details without loss and suppress the impulse noise interference. The results of computer simulation and the experimental data processing show the effectiveness of the method.

Impulsive Noise Model

De-noising is an important pre-processing in the process of the telemetry environment parameters. The traditional telemetry environmental parameter data processing often assume the noise meet the Gaussian distribution, which can be suppressed by the filtering or least square fitting method. Also the wavelet threshold de-noising is an effective de-noising method for Gaussian noise, wavelet de-noising does not need signal is stationary. However, with the multi-user interference, atmospheric noise (thunderstorms, lightning), discharge of car engines, and other natural and man-made electromagnetic interference, the noise in the telemetry received signals often exhibit impulsive noise characteristics. In recent years, impulse noise is widely regarded in some engineering applications, typically a microphone array speech signal acquisition system and the naval vessel sonar system, the noise shows typical characteristics of impulse noise. Impulse noise is different from the Gaussian noise, which has short greatly significant pulse in the time domain. In the engineering, the alpha stationary distribution is often used to describe the impulsive noise, which is an applicable to a wide range and has been widely used. The characteristic function can be given by

$$\phi(t) = \exp\{j\mu t - \gamma|t|^{\alpha}[1 + j\beta\,\mathrm{sgn}(t)\omega(t,\alpha)]\} \tag{1}$$

$$\omega(t,\alpha) = \begin{cases} \tan(\pi\alpha t) & \alpha \neq 1 \\ (2/\pi)\log|t| & \alpha = 1 \end{cases} \tag{2}$$

where α, γ, β and μ are the parameters to describe the alpha stationary distribution. α is the characteristic exponent, γ is the coefficient of dispersion, β is the symmetric parameter and μ is the mean or median of the alpha stationary distribution.

Wavelet Transform and Median Filtering

Wavelet analysis has been widely used in engineering for signal processing, and the wavelet threshold de-noising can obtain good performance for the Gaussian noise. However, if the noise does not meet the Gaussian distribution, the wavelet threshold de-noising performance would degrade, especially for the impulse noise. The median filtering is a kind of impulse noise suppression method as the nonlinear filtering techniques, but the median filtering with fixed window size has contradictory in the signal details protection and impulse noise suppression ability. In order to solve this problem, we can combine the median filtering with wavelet transform to construct a multi scale median filtering method.

Wavelet transform can be equivalent to a set of image filtering process, in which the signal through a decomposition of high pass filter and low-pass filter, and then the high frequency part of signal corresponding to the natural high pass filter, called the detail component, the output low-pass filter corresponding to the lower part of the relative frequency component signal, called the approximate components. The fast algorithm of wavelet transform is Mallat algorithm, which based on wavelet decomposition and reconstruction algorithm of wavelet theory respectively, as shown in Fig.1 and Fig.2.

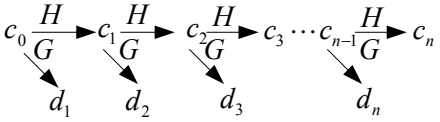

Fig.1 The tower decomposition algorithm

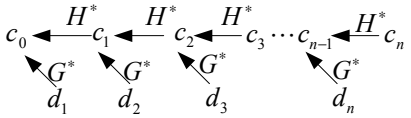

Fig.2 The tower reconstruction algorithm

where H and G are corresponding to the high-pass filter and the low-pass filter respectively, H^* and G^* are the dual operator of H and G. c_j and d_j （$j = 1,2,\cdots,n$） are the approximation component and detail components respectively.

Although wavelet decomposition is an iterative process, which can break down the infinite in theory, but in the practical application, it is decomposed into a finite number can meet the needs of the signal processing and analysis.

Median filtering is a nonlinear filtering method, in which the signal filtering based on the order statistics, and it has the advantages of simple and fast operation, with has excellent performance in impulsive noise suppression. For the one-dimensional median filtering, let the filter window length $n=2k+1$ or $n=2k$ and the sampling points $N \geq n$, when $U(t_1)$, $U(t_2)$, $\cdots$, $U(t_N)$ moving on the observation data, the output of the median filtering is given by

$$med(U(t_i))=\begin{cases} U(t_{k+1}) \\ \frac{1}{2}\left[U(t_k)+U(t_{k+1})\right] \end{cases} \tag{3}$$

where $U(t_k)$ is the k-th maximum or minimum in the window $n=2k+1$ or $n=2k$. According to this definition, the output $X(t_i)$ and the input $U(t_i)$ of the median filtering can be expressed as

$$X(t_i)=med\left[U(t_{i-k}),\cdots,U(t_{i+k})\right] \tag{4}$$

According to the process of the median filtering, the window size has an important influence on the performance. Typical if the median filter window smaller or equal to the width of the pulse, the pulse will be retained after filtering. If the pulse width is less than or equal to the window size, the pulse will be removed after filtering. Therefore, the median filtering window with better impulse noise suppression ability, the detail information of high frequency would loss seriously. Otherwise, the median filtering window is smaller can have the good protective capability for signal details, but the impulse noise suppression ability is weak, especially for some short impulse noise, often do not get ideal results.

Therefore, we can decompose signal into a series of detail components and approximate component by wavelet transform, and using different filter windows on the wavelet decomposition components for median filtering, as a result, a method can keep the detail information of signal and suppress the impulse noise as the same time is obtained.

The Simulation and Experimental Data Processing

The simulation signal is given by

$$x(t)=\sum_{i=1}^{3}\sin(2\pi f_i t)+n(t) \tag{5}$$

where the sample frequency $f_s=1000\,\text{Hz}$, the center frequency of is $f_1=50\,\text{Hz}$, $f_2=20\,\text{Hz}$, and $f_3=5\,\text{Hz}$. $n(t)$ is the impulse noise. The simulation results are shown in Fig.3a-Fig.3c. The results show that, the multi scale median filtering method can suppress the impulse noise and keep the detail information of the signal effectively. To further verify the effectiveness of the method, the vibration signal in a test is selected to process and the sampling frequency $f_s=5\,\text{Hz}$. The processing results are shown in Fig.4a-Fig.4c. The results can also show the effectiveness of the multi scale median filtering combined with wavelet transform.

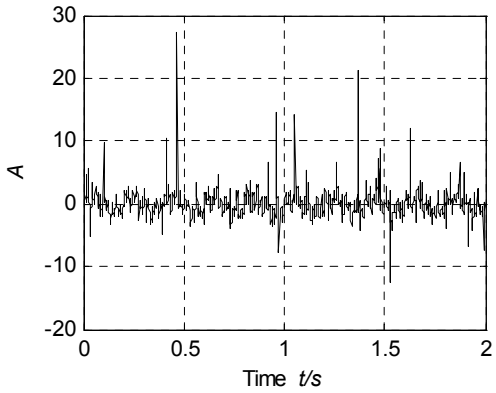

Fig.3a The simulation signal

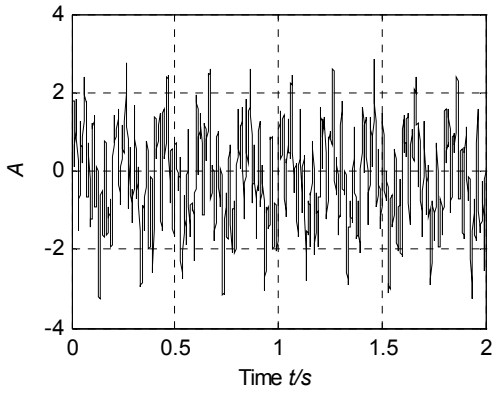

Fig.3c Multi scale median filtering result

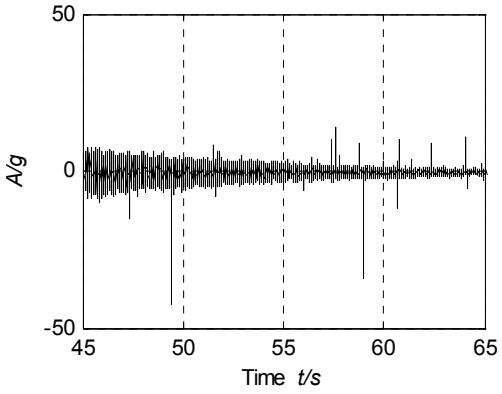

Fig.4a Vibration signal

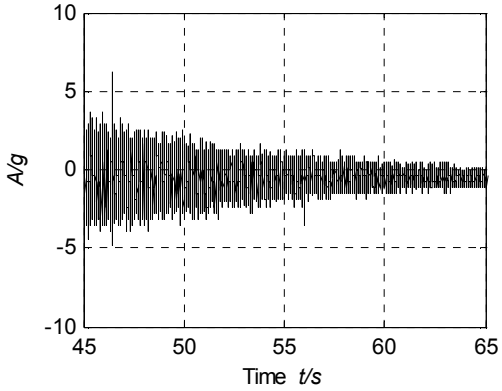

Fig.4b Median filtering result

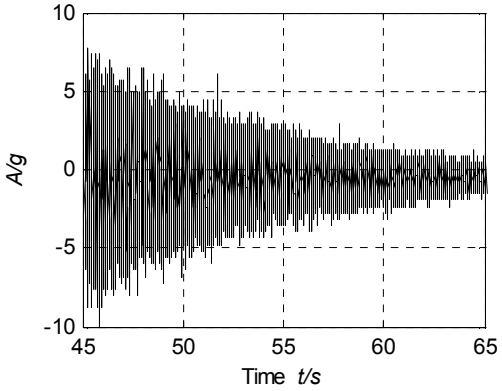

Fig.4c Multi scale median filtering result

Conclusion

This paper proposed a multi scale median filtering to suppress the impulse noise in the signal, which takes advantages of the wavelet transform and the median filtering to overcome the shortage of the median filtering with the fixed window size. The simulation and the vibration signal processing results show the method can suppress the impulse noise and keep the detail information of the signal effectively.

Research on color vegetable diseases in greenhouse image pretreatment and extraction method

Luo Xiao-li

Fuzhou Vocational and Technical College Fuzhou Fujian China

email:2416734036@qq.com

Keywords: Sobel-operator, channel, circular degree, weighted mean square error

Abstract. In order to realize the accurate identification of the image color vegetable diseases in Greenhouse, In this paper, by using computer image processing technology in the intelligent recognition of vegetable diseases in greenhouse leaf, First, the moving average method can effectively remove the noise by the image of R,G, B three channel gray level, Then separate three channel image using Sobel -operator and the 4 template based on the direction of gradient magnitude ,and then integrate the three channel edge ,it can overcome the shortcoming of traditional gray image information, and make up the deficiency of the traditional Sobel operator edge thinning geometric features.

Introduction

In abroad, [1] Shanwengang studied the infrared image of the harmful Sulfur dioxide gas pollution on crop In 1985 ;[2] later the Japanese Honami Nobuo separately samplied image to the arrowhead leaf of the lack of calcium, iron, magnesium nutrient elements by computer vision technology in the open , As the shape and position of the leaf image histogram a feature. But by the extracted features to distinguish the effect is not obvious.[3] At home, in the early 1990 s, the computer image processing technology applied in the field of agricultural engineering, mainly was used in the agricultural product quality inspection and grading, crop information retrieval. [4] Such as Jian Ping (1993) has used image processing technology to make more reasonable for tobacco appearance quality detection, synthesize variety of colorimetric system on the quantitative analysis of the quality of tobacco leaves.

The purpose of image processing is to get image edge from a true color image of plant disease. Through the disease imaged by CCD camera as the research material, have finished the output of plant disease image edge geometry information and prepared for the subsequent computer to diagnose diseases.

The research environment and technical methods

study Visual C++ software on Windows XP platform 6, 0 as a development tool, Edit programs to image preprocessing, Eventually form a complete image processing system. This project research method is based on digital image processing technology, as the theoretical basis of algorithm analysis, through the CCD camera image, study computer disease image edge scheme for greenhouse vegetables to achieve intelligent extraction disease geometric edge.

Image preprocessing

2.1 [6] channel separation:

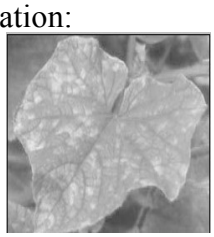

Fig.1Red channel

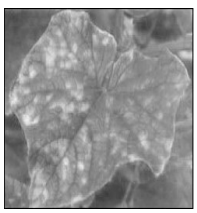

Fig. 2 Green channel

Fig. 3 Green channel

An image of RGB mode, with red, green and blue color values：True color RGB model with R, G, B three channel color, the color of each image channel window is displayed in gray image, the disease spot image edge and background will appear obvious gray contrast in each channel, and this provide the guarantee for the image edge extraction of the accurate. Use Photoshop to open the cucumber owny mildew leaf image into the channel view, get the following R, G, B three channel gray image as figure 1,2,3.

By contrast degree of three channels of gray image disease spot and leaves, set the weight of the red channel, the green channel, blue channel with 0.2, 0.7, 0.1set the weight of the red channel.

2.2 image denoising

[5]In the 3*3 area as the neighborhood of Z, the median filtering technology is on the basic principle of pixel numerical order except the center point of the median values, obtained The median values in the neighborhood, Gray pixel neighborhood center point values are replaced by the mid-value of group. The pixel of the centre is close to the real values, so as to eliminate the isolated noise points. f (x, y) is the original map images , F (x, y) two-dimensional median filter output , F (x, y) =med{f (x-m, y-l), (m, l ∈ Z)}. Out images using three channel gray on the separation based on the median filter, the median filter not only solves the problem moving smooth resulted in details but also solves overexpression of smooth and edge deletion etc by the traditional Gauss function .

Feature extraction,

First through image segmentation, using double threshold segmentation technique to remove background, so as to separate the image information and the background information, then by using four template Sobel-operator respectively calculated gradient amplitude of three-channel image edge detection, edge can be fully refined, finally, the geometrical characteristics of the disease spot can be fully extracted by fusing three-channel with weighted mean square erro.

3.1, the image segmentation

Due to the color of the leaf is darker than the disease spot, brighter than the background, so we can adopt double value binarization processing [6]

$$G(x,y)=\begin{cases} HIGH & (T1<F(x,y)<T2) \\ LOW & else \end{cases} \quad (1)$$

As an example of Green channel gray image, first, extract the image below a threshold value less than 128 as fgure 4; Then the image reversaed we can extract the image of threshold value larger than 140 as figure 5; Finally extract the image of threshold between 128 to 140 to get the following figure 6 which is the best effect:

Fig.4 Threshold < 128

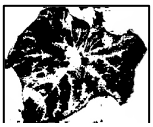

Fig.5 Threshold > 140

Fig.6Threshold of 128 ~ 14

3.2,Image edge detection:

use 4 template direction of Sobel-operator respectively calculate gradient amplitude of three-channel image edge detection.For Green channel gray image as an example, using the 3×3 matrix, the horizontal and vertical, respectively, with the image plane convolution, can be calculated the brightness of the horizontal and vertical difference approximation. [7] if A on behalf of the original image, Gx and Gy represent the horizontal and vertical edge detection of image, its formula is follows:

$$G_x = \begin{bmatrix} -1 & 0 & +1 \\ -2 & 0 & +2 \\ -1 & 0 & +1 \end{bmatrix} * A \text{ and } G_y = \begin{bmatrix} +1 & +2 & +1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix} * A \qquad G_{45度} = \begin{bmatrix} -2 & -1 & 0 \\ -1 & 0 & +1 \\ 0 & 1 & +2 \end{bmatrix} * A \text{ and } G_{135度} = \begin{bmatrix} 0 & +1 & +2 \\ -1 & 0 & +1 \\ -2 & -1 & 0 \end{bmatrix} * A \quad (2)$$

Then the following formula can be used to compute the gradient direction.

$$\Theta = \arctan\left(\frac{G_y}{G_x}\right) \quad (3)$$

The image edge detection should has many directions: except in the horizontal directions , add the vertical directions and 45 degree, 135 degree directions, so as to improve the accuracy and can achieve real-time detection of edge effect .the image as the follows figure 7,8,9

THE FUSION OF THE THREE CHANNEL EDGE

Fig.7 G channel X and Y Sobel operator

Fig.8 G channel 45 ° and 35 ° Sobel operator

Fig.9 G channel four directions of 45 ° and 35 ° Sobel operator

Because of the B channel carrying more edge information of color image than R, G channels. Therefore, their right importance are larger.[8] So three channel fusion method set R, G, B channel weight fx respectively 0.7, 0.2, 0.1 by calculating the variance of three channel edge image, the deviation from the mean square variance, known as the standard deviation or variance, the variance to describe fluctuations. The more close to the true value if the fluctuation of small, obtain the value, or abandon, a point （x,y） in three channel edge image Gray value respectively is HR, HG , HB, There are：

Average Value: $E=0.2H_R + 0.7H_G + 0.1H_B$ (4)

Variance : $s_{R\wedge 2}= 0.2(H_R-E)\wedge 2 \quad s_{G\wedge 2}= 0.7(H_G-E)\wedge 2 \quad s_{B\wedge 2}= (H_B-E)\wedge 2$ (5)

Three channel edge images before image fusing as Figure10, Figure11, Figure12:

Fig.10 The red channel edge detection

Fig.11 The red channel edge detection

Fig.12 The red channel edge detection

Fig.13 The image after Three channels edges fused

So, with different weights to fuse the three edge detection image results information as the figure 13:

From the edge detection results as Figure 13, the closed area in the picture is the leaf spot, we can calculate roundness, area, perimeter as follows Table 1 :

TABLE .1 CUCUMBER LEAF DISEASE SPOT IMAGE CHARACTERISTICS

lesion area ID	Area Ar	Premeter Gir	Roundness Rou
0001	0.13	1.23	1.08
0002	0.10	1.17	0.91
0003	0.12	1.41	0.75
….	….	….	…..

Conclusion

If lesion area is small, it located at the blade tip, the circular degree nearly circular, damage to a lesser degree. When the area is large, the lesion area closed area, located at the blade tip round degree difference, the shape are irregular and the damage is more serious.

An Infrared and Visible Images Fusion Algorithm Based on Wavelet Multi-resolution Decomposition

Likun LIU, Zongjia WU

PLA 91550 Unit 94, Liaoning Dalian, China

tianyafc@163.com

Keywords: Image Fusion, Multi-resolution Decomposition, Bivariate Statistical Model

Abstract. Image fusion can be effectively utilized to obtain image redundant information from sensors, hereby improving the accuracy and reliability of information. Based on multi-resolution decomposition of the traditional image fusion method is vulnerable to high frequency noise, fusion is often ineffective. An improved image fusion algorithm has been studied based on the wavelet multi-resolution decomposition. The principle of the algorithm is regional energy maximum for low frequency decomposition image, and the bivariate statistical model for high frequency part. Experimental results show that the bivariate statistical model for the high frequency band is robust to noise based on the joint probability of wavelet coefficient in the conditions of Daubechies wavelet basis function with decomposing level 5 multi-resolution decomposition. Simultaneously, the regional energy maximum for low frequency band can be effective on the high frequency band based on the bivariate statistical model. Fusion image have a larger contrast, the preferred details and the higher gray level resolution.

Introduction

The basic idea of multi-resolution image fusion method is to use multi-resolution decomposition transformation of the source image, and then synthesized multi-resolution image fusion coefficient by some fusion rules, the final inverse transform using multi-resolution image fusion. However, the methods are susceptible to high frequency noise interference. To solve this problem, researchers proposed a fusion method based on the mathematical statistics of high-frequency image. Expectation maximization algorithm [3] for image fusion was used by Yang J. Lafert [4] has proposed statistical fusion model in different resolution image fusion.

In this paper, image multi-resolution analysis based on wavelet decomposition is firstly studied, then, image fusion algorithm has been proposed on multi-sensors image model, which is region energy maximum for low frequency band and bivariate model with the joint probability of wavelet coefficient pair(a wavelet coefficient and its parent) for high frequency band, lastly, with the inverse transform, the infrared and visible images fusion has been achieved.

Image Fusion based on Wavelet Transform

Multi-layer decomposition of the image, each layer produce four sub-images ILL, IHL, ILH, IHH, of which, ILL focus on the main low frequency part, IHL corresponds to the level of the direction of the high frequency information, and ILH corresponds to the vertical direction, IHH corresponds to the direction of 45 degrees.

Mallat proposed the fast algorithm of wavelet transform from the function of multi-resolution [5] [6].

Wavelet transform method generally has the following four steps.

Step1.To match two source images;

Step2. The wavelet decomposition of a source image to create an image wavelet pyramid image;

Step3. For each decomposition level fusion processing, the wavelet coefficients of each decomposition, according to the characteristics of the different frequency components, using different fusion rules for fusion, the formation of the wavelet decomposition pyramid image fusion;

Step4. Fusion of the wavelet pyramid, the inverse wavelet transform for image reconstruction, the formation of the fused image.

Fusion Rules of the Mathematical Model

Low frequency band of the fusion rules has been based on the largest regional energy integration rules. $E_{K,J}(x,y)$ Indicates that the size of the area (x, y) in the low frequency coefficient matrix $M \times N$ of energy, expressed as

$$E_{K,J}(x,y) = \sum_{m \in M, n \in N} \left[C_{K,J}(x+m, y+n) \right]^2 \tag{1}$$

Value in the region expressed as,

$$MED_{K,J}(x,y) = \sum_{m \in M, n \in N} \frac{C_{K,J}(x+m, y+n)}{M \times N} \tag{2}$$

If $Mat_{K,J} \le Thr$, low frequency coefficient is,

$$F_J(x,y) = \begin{cases} C_{A,J}(x,y), & \left(E_{A,J}(x,y) \ge E_{B,J}(x,y)\right) \\ C_{B,J}(x,y), & \left(E_{A,J}(x,y) < E_{B,J}(x,y)\right) \end{cases} \tag{3}$$

If $Mat_{K,J} > Thr$, low frequency coefficient is

$$F_J(x,y) = \frac{MED_{A,J}(x,y) + MED_{B,J}(x,y)}{2} \tag{4}$$

Where, Thr matches the threshold for the image, $Mat_{K,J}$ is the matching of two images corresponding to the regional energy, the size of the area is generally 3×3,5×5 or 7×7, in our study, 3×3 is selected.

The fusion of high frequency band is based on mathematical model [7] of the sensor and the bivariate statistical model [8][9]. In the case of not appear to be confused, in order to facilitate the derivation, the superscript H is omitted, and high-frequency part of the model rewritten in vector form, as shown below

$$\alpha = \beta s + \varepsilon \tag{5}$$

Where, $\alpha = \left[\alpha_1, \alpha_2, \cdots, \alpha_q\right]^T$, $\beta = \left[\beta_1, \beta_2, \cdots, \beta_q\right]^T$, $\varepsilon = \left[\varepsilon_1, \varepsilon_2, \cdots, \varepsilon_q\right]^T$.

Assume that the noise is no-correlative between each other in sensors. Then, we can get a diagonal noise covariance matrix $\sum_{\varepsilon} = diag\left[\sigma_{\varepsilon_1}^2, \sigma_{\varepsilon_2}^2, \cdots, \sigma_{\varepsilon_q}^2\right]$.

The Eq.5 can be used estimation theory to solve. The maximum a posterior estimator (MAP estimator) and bivariate statistical model will be used to solve this problem.

Based on the above assumptions, we can get

$$\alpha_1 = \beta_1 s_1 + \varepsilon_1 \tag{6}$$

$$\alpha_2 = \beta_2 s_2 + \varepsilon_2 \tag{7}$$

The two equations above can be rewritten in the following form

$$A = BS + n \tag{8}$$

Where, $A = (\alpha_1, \alpha_2), B = (\beta_1, \beta_2), S = (s_1, s_2), n = (\varepsilon_1, \varepsilon_2)$

Using MAP

$$\hat{S}(A) = \arg\max_S p_{S|A}(S \mid A) \tag{9}$$

With Bayes rule

$$\hat{S}(A) = \arg\max_S [p_{A|S}(A \mid S) \cdot p_S(S)] = \arg\max_S \left[p_n(A - BS) \cdot p_S(S) \right] \tag{10}$$

Noise probability density function can be written as

$$p_n(n) = \frac{1}{2\pi\sum_{\varepsilon}} \cdot \exp\left(-\frac{\varepsilon_1^2 + \varepsilon_2^2}{2\sum_{\varepsilon}} \right) \cdot \tag{11}$$

Then

$$\hat{S}(A) = \arg\max_{S}[\log(p_n(A - BS)) + \log(p_s(S))] \tag{12}$$

The above equation is equivalent to the solution of the following equation

$$\frac{\beta_1^T(\alpha_1 - \beta_1 \hat{s}_1)}{\sum_{\varepsilon}} - \frac{\sqrt{3} \cdot \hat{s}_1}{\sigma_s \sqrt{(\hat{s}_1)^2 + (\hat{s}_2)^2}} = 0 \tag{13}$$

$$\frac{\beta_2^T(\alpha_2 - \beta_2 \hat{s}_2)}{\sum_{\varepsilon}} - \frac{\sqrt{3} \cdot \hat{s}_2}{\sigma_s \sqrt{(\hat{s}_1)^2 + (\hat{s}_2)^2}} = 0 \tag{14}$$

Fusion Simulation

Fig.1 (a) and (b) are respectively the infrared and visible image (from the Dutch TNO Human Factors Research Institute) [10]. From Fig.1 (a), there are several residential buildings in the scene, on the lawn in front of the house to release smoke from the smoke source. In the infrared image, next to the houses there was a man can clearly be seen, but other scenes are rather ambiguous. In the visible image, the house behind the trees and the grass in front of the house and on the left side of the outline is very clear, but part of the structure behind the house and the smoke obscured completely invisible, due to smoke, visible image in Fig.1 (b) of the same scene, difficult to identify the target in Fig.1 (a), but the scenery of the grass, trees, sky. Using 3×3 local analysis size, the wavelet decomposition level of 5(Db3 wavelet basis function). The fusion results are shown in Fig. 2. Other methods of fusion images are shown in Fig.3 (a)-(f).

Conclusions

In this paper, image fusion algorithm based on multi-resolution decomposition was studied, which includes the low frequency band and high frequency band image fusion. Fusion rule is a very important in the image fusion algorithm, which relates to the stability of the fusion algorithm, efficiency and the image quality. The bivariate statistical model for the high frequency band is robust to noise based on the joint probability of wavelet coefficient pair. Experimental results show that, using the algorithm proposed can obtain good quality of the fusion image, compared with other algorithms, the effect of the proposed method is better.

Keywords： blind source separation; rolling element bearing; fault diagnosis; Kurtosis

Abstract . In order to extract the fault information from rolling element bearing, combined with Kurtosis criteria and Hessian matrix. An improved rolling element bearing fault signal extraction method is proposed. Kurtosis is the cost function. The method is according to the construction principles of blind source separation (BSS), and it uses an analytically derived Hessian matrix in the maximization process of the cost function used. Then the impact signal is extracted successfully. The effectiveness of the method is demonstrated on simulated signal.

Introduction

Rolling element bearings are one of the most extensively used element in rotary machine, and they also play a key role and an easily damaged components in the whole system [1]. Vibration monitoring methods are more applicable to various kinds of rolling element bearings, and especially suitable for incipient fault monitoring and online monitoring. Vibration monitoring methods are widely used in the monitoring and diagnosis of rolling element bearing [2].

On the study of the rolling element bearing of general equipment many scholars have achieved valuable fruits from different angle of view. The common methods such as envelope analysis, wavelet analysis and so on have obtained a certain effect in engineering application [3]. However, because of multiple vibration exciting sources and the complex transfer path, the rolling element bearings fault diagnosis of the complex structure equipment belongs to the weak fault extraction field under multiple excitation sources and strong background noise. In addition, the transfer characteristics trend to unknown for engineering applications which make it hard to the fault recognition [4]. When the transfer characteristics and the number of signal resources are unknown, BSS is a method which utilizes the statistics feature of resource signals and the signals obtained by transducer to extract or separate the resource signals. The BBS method possesses superior performances because of it has taken full advantage of the independence between different resource signals. Hence we can use the BBS to extract the rolling element bearings fault feature of the complex structure equipment [5][6].

In this article, the structure and principles of BBS method is introduced. Kurtosis is regarded as the cost function and an analytically derived Hessian matrix in the maximization process of the cost function is used, and then the separation of rolling element bearing fault signal is achieved. Analysis results for the simulated signals show the effectiveness of the proposed fault extraction approach.

The basic principle and algorithm

Fundamental. The BBS method has good performance. $\mathbf{S}(k)=\left[s_1(k) \quad s_2(k) \quad \cdots \quad s_N(k)\right]$, where $s_n(k)$ is the nth input vibration exciting source, $\mathbf{y}(k)=[y_1(k), y_2(k),\ldots, y_M(k)]$, where $y_m(k)$ is the mth output measurement signal, at a sampling time k. The mechanical system is described as a discrete time system, and matrix $\mathbf{H}$ is the transfer function matrix between exciting and response. We define $\mathbf{y}(k)=\mathbf{H}(z)\cdot\mathbf{S}(k)$

$$y_i(k)=\sum_{i=1}^{M}\sum_{l=0}^{L_c} H_{i,j}(l)S_j(k-l),\ \ i=1,2,\ldots,M,\ \ j=1,2,\ldots,N \tag{1}$$

In the actual projects, multiple exciting sources and the transfer function of the mechanical system is unknown. The following four assumptions are made:

1. The exciting sources are zero mean and independent.
2. The fourth-order cumulants of all the components of the exciting sources are non-zero.
3. **H** is FIR.
4. No measurement noise is present.

When bearing surface defect is generated, impulse signal is excited and the value of Kurtosis increased along with it. We use Kurtosis as the cost function to construct the BBS algorithm, and the fault signal is separated. The Kurtosis is defined as:

$$\text{（Kurtosis）}\quad J=\frac{E(S_i^4)}{(E(S_i^2))^2}-3 \tag{2}$$

The basic approach is depicted in Fig. 1. This method uses independent inverse filter **W** to the measurements **y** resulting in the estimated separated sources S_e. The coefficients of **W** will be iteratively updated until the cost function is maximized. Finally, the fault signal is separated efficiently.

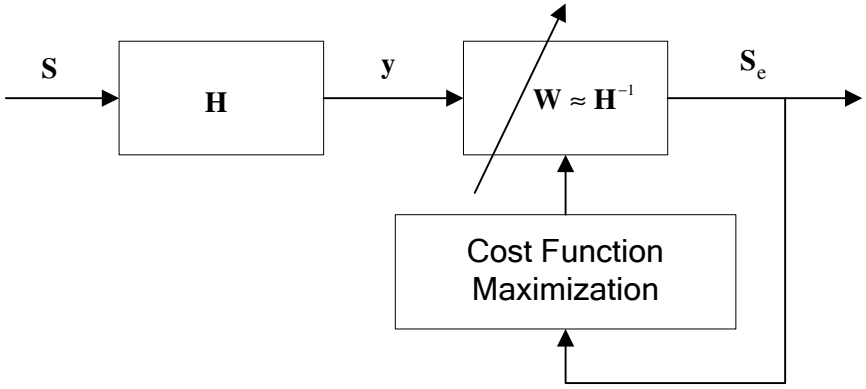

Fig. 1. The basic method

The inverse filter and its coefficients are defined as follows:

$$\mathbf{W}_{i,j}(z)=\sum_{l=0}^{L-1}W_{i,j}(l)z^{-l},\quad W_j=\begin{bmatrix}W_{1,j} & \cdots & W_{M,j}\end{bmatrix} \tag{3}$$

where L is sufficiently large for an reasonable approximation.

Applying the inverse filters to the measurements results in the estimated sources S_e. S_e is defined as:

$$s_{ej}(k)=\sum_{i=1}^{M}W_{i,j}(z)y_i(k)=\sum_{i=1}^{M}\sum_{l=0}^{L-1}W_{i,j}(l)y_i(k-l) \tag{4}$$

$$s_e(k)=\sum_{i=1}^{M}\sum_{l=0}^{L-1}W_i(l)y_i(k-l) \tag{5}$$

Newton iteration algorithm. The coefficients of inverse filter $W_i(l)$ can be obtained by Newton iteration algorithm. The Hessian matrix **H** is given by

$$H_{m,n}=H_{(i1\times l1)\times(i2\times l2)}=\frac{\partial^2 J}{\partial w_{i_1,j}(l1)\partial w_{i_2,j}(l2)},\quad i_1,i_2=1,\ldots,M,\quad l_1,l_2=1,\ldots,L \tag{6}$$

$$W_{i,j}^{q+1}(l)=W_{i,j}^{q}(l)-\left[H_j^q\right]^{-1}\frac{\partial J(W_{i,j}^q(l))}{\partial W_{i,j}^q(l)} \tag{7}$$

where q is the index of iteration.

The process of using Newton iteration algorithm to solve inverse filter $W_i(l)$ are as follows:

1. Initialize the inverse filter W_0.
2. Define q=0.
3. Calculate the Hessian matrix $\mathbf{H}$.
4. Define $Z^{(q)} = -\mathbf{H}^{-1}\frac{\partial J}{\partial W}$, the iteration stopped until $\left|\frac{\partial J}{\partial W}\right| < \varepsilon$, and the $W^{(q)}$ is obtained, otherwise goes to step 5.
5. Calculate S_k to makes $J(W^{(q)} + S_k \cdot Z^{(q)}) = \max(W^{(q)} + S_k \cdot Z^{(q)})$.
6. Define $W^{(q+1)} = W^{(q)} + S_k \cdot Z^{(q)}$, $q = q+1$, return to step 3.

After $W^{(q)}$ is obtained, we can also get $W_i(l)$. Namely use equation (6) to obtain S_e.

The above process, shown by Fig. 2 identifies a single estimated source.

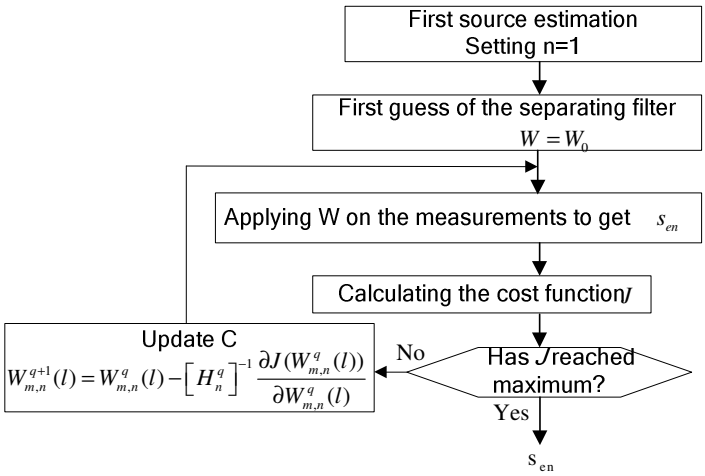

Fig. 2. Algorithm flow chart for single source estimation.

Using this known source, we now estimate the coefficient of the mixing matrix $\mathbf{H}$ related to this source.

The filters $f_{m,n}(l)$ are estimated from y_m and s_{en} using

$$\hat{f}_{m,n}(l) = \frac{E\{y_m(k)s_{en}(k-l)\}}{E\{s_{en}(k)^2\}}, \quad n = 1,2,\ldots,N, \quad m = 1,2,\ldots,M \tag{8}$$

The contribution of the estimated source to each measurement is now computed, as the component of s_{en} in y_m:

$$\hat{y}_{m,n}(k) = \sum_l \hat{f}_{m,n}(l)s_{en}(k-l) \tag{9}$$

Subtracting $\hat{y}_{m,n}(k)$ from y removes the nth source components from the measurements and thus allows the separation of the next (n+1) source in the same way. The process is stopped when no maximum is found.

Simulation studies

In order to validate the correctness and validity of the rolling bearing fault signal extraction method based on the BBS algorithm, the simulation signal of rolling bearing surface fault was studied and analyzed.

Simulated signal. The signals are typical of structural systems excited by impacts, i.e. periodic trains of decaying oscillations. These types of signals are often considered as models of faulty bearing vibrations. A rolling element bearing vibration model which is consist of three vibration

exciting sources is shown in Fig. 3(a). $s1(t)$ is the triangular-wave pulse, namely the impact pulse caused by bearing defect. $s2(t)$ and $s3(t)$ are sine wave, namely interrupt exciting sources. The three sources $s1(t)$, $s2(t)$ and $s3(t)$ are modified by structural resonances to nine signals which are shown in Fig. 3(b).

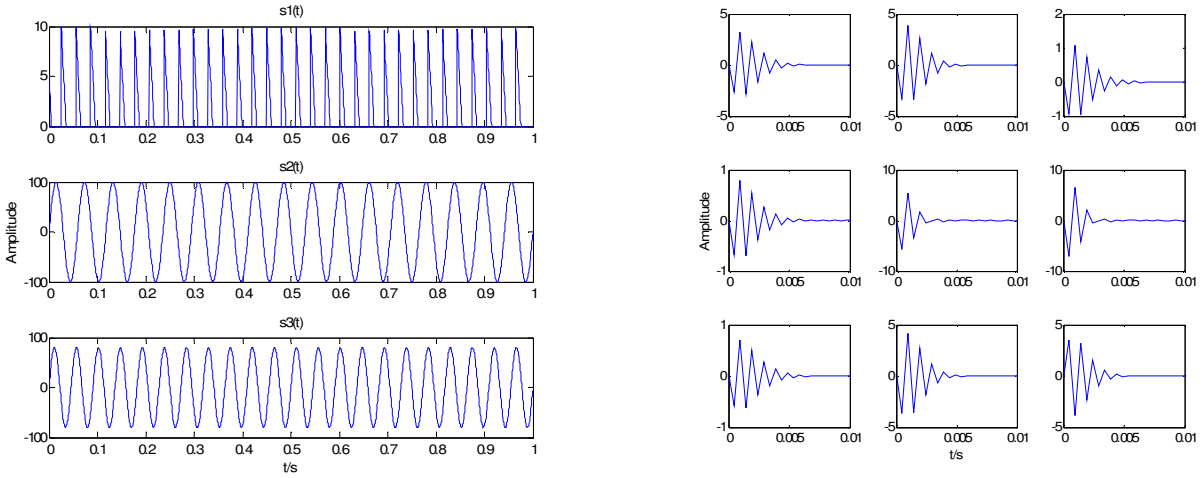

Fig. 3. (a) Vibration exciting sources (b) modified signals

In early stage of bearing failures, the feature information is usually buried by strong background noise coming from gear meshing vibration, mass unbalance, misalignment, etc. The three vibration exciting sources are modified by structure resonances and mixed in some arbitrary combination to produce the measured signals shown in Fig. 4, the fault impact can not be seen clearly from $y1(t)$.

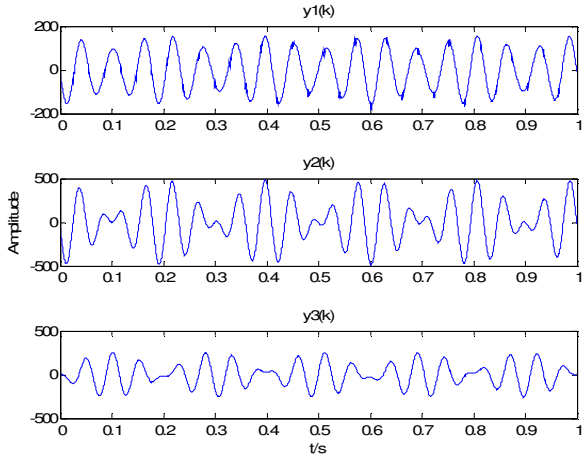

Fig. 4. Measured signals

Verification and analysis. The BBS algorithm is applied to simulation measured signals. Newton iteration algorithm is applied to calculate the inverse filter $W_i(l)$, namely it uses a Hessian matrix to maximize the cost function. This is a loop iteration process, and the inverse filter updating itself constantly until the Kurtosis reaches the maximum. Then the optimum inverse filter is obtained, and the optimum inverse filter is shown in Fig. 5(a). The fault signal S_e which is calculated with formula (6) is shown in Fig. 5(b). In the extracted signal, the fault impact can be seen obviously. The fault signal is obtained successfully through the BBS algorithm. Hence, the effectiveness of the method is demonstrated on simulation.

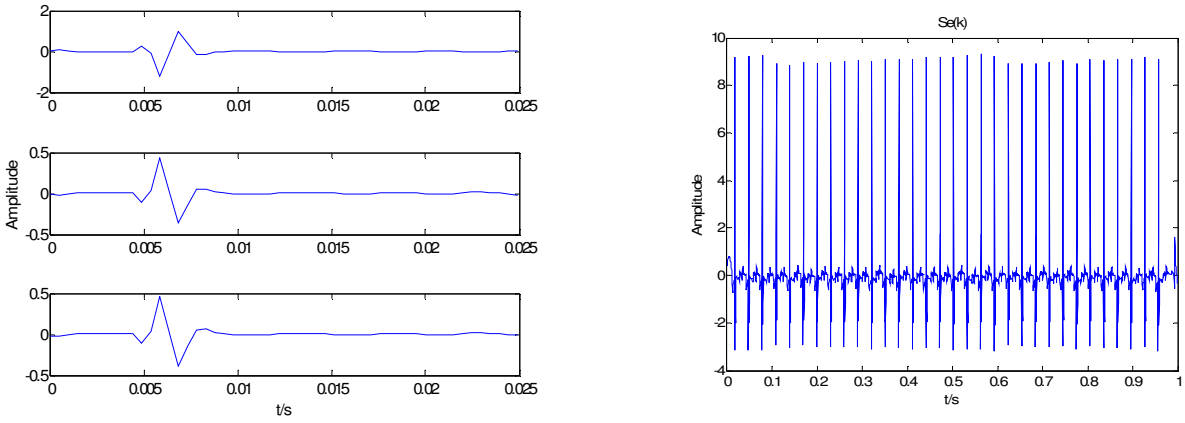

Fig. 5. (a) Optimum inverse filter (b) extracted signal

Conclusions

In this paper, the principle of BBS algorithm is analyzed at first. Then the method named rolling bearing fault signal extraction based on the BBS algorithm is proposed. In this method, Kurtosis is the cost function, and the inverse filter is obtained through the Newton iteration algorithm. Then the fault signal is obtained. The effectiveness of the method is verified by processing simulation signal of rolling element bearing. Future work should investigate the application of measured signals.

The Improved Membership Matrix Initialization Method of FCM for Image Segmentation

Zong-jia WU, Li-kun LIU

PLA 91550 Unit 94, Liaoning Dalian, 116023, China

email: zjw1980221@126.com

Keywords: Membership Matrix; FCM; Initialization method; Image Segmentation

Abstract. The performance of FCM for image segmentation directly subjects to the initialized membership matrix. This paper proposed twice FCM method to solve the membership matrix initiation problem. The image is spared to a blurred image at first, and then uses the FCM for the blurred image to obtain an iterative result, in which the membership matrix is taken as the initialized membership function of the FCM for the original image processing. This method overcomes the random membership initialization method cannot convergence to the optimum point of the objective function of FCM for the image segmentation at some extend, furthermore, it can obtain better results than the traditional FCM method.

Introduction

Image segmentation is one of the most basic and important field in image processing, it is the basic premise for visual analysis and pattern recognition to the image. Image segmentation is based on some characteristics of an image is divided into several meaningful regions, the characteristics of identical or similar in a certain area, but in different regions are obviously different. Classical image segmentation methods include threshold method, region growing method, relaxation method, edge detection method and the split and merge method [1], modern methods include neural network and fuzzy clustering method [2]. Different methods are suitable for different fields of application, for the large scale image data mining research, the efficiency of the algorithm, automatically (without human intervention) ability is very important for classification and prediction. In essence, image segmentation is a process of classifying the pixel based on some attribute, and because of the image complexity of the clustering problem with uncertainty, so from the point of view of fuzzy clustering image segmentation problem is a feasible idea.

Fuzzy C means (FCM) algorithm [3] is a classical algorithm to solve the fuzzy clustering problem. The computational efficiency is robust and has good performance. Its disadvantage is that there is no general method to determine the weighted index and the number of clusters, it has more subjectivity [4], the clustering problem is only applicable to the class number is known, but the number of categories is one of the characteristics of the data structure, which is great importance to the image content understanding, and it is the goal of image mining. The performance of FCM for image segmentation directly subjects to the initialized membership matrix, if the membership matrix is random initialized, the iterative algorithm often drop into the local point of the objective function. Aiming at this problem, this paper proposes a membership initialization method to solve this problem. The image is spared to a blurred image at first, and then uses the FCM for the blurred image to obtain an iterative result, in which the membership matrix is taken as the initialized membership function of the FCM for the original image processing. The simulation results show the effectiveness of this method can avoid the local point of the objective function and obtain the better image segmentation result than traditional FCM method.

The Improved Fuzzy C Means Clustering Algorithm

Fuzzy C means clustering algorithm is proposed by Dunn [5], and Bezdek improved FCM algorithm by using the weighted index, which is the often used in the application. FCM algorithm is a clustering algorithm based on partitioning, which makes the idea is to be divided into the biggest

similarity between objects on the same cluster, while the minimum similarity between different clusters. Fuzzy C means algorithm is an improvement of common C means algorithm, C means algorithm for data classification is rigid, while the FCM is a flexible fuzzy partition. According to the weighted index FCM algorithm, the algorithm is to minimize the objective function which can be given by

$$J(U,c_1,\cdots,c_c)=\sum_{i=1}^{c}J_i=\sum_{i=1}^{c}\sum_{j=1}^{n}u_{ij}^m d_{ij}^2 \tag{1}$$

where n is the total number of samples, $U=(u_{ik})_{n\times c}$ is the membership matrix, u_{ik} is the element of the membership matrix with the constraint conditions as follow

$$\begin{cases}\sum_{i=1}^{c}u_{ik}=1 & k=1,2,\cdots,n\\ u_{ik}\geq 0 & i=1,2,\cdots,c\end{cases} \tag{2}$$

c_i is the clustering center of the fuzzy set i, $d_{ij}=\left\|c_i-x_j\right\|$ is the Euclidean distance between the clustering center and the j-th data point. $m>1$ is a weighted index. To minimize the objective function Eq.1, it can construct a new objective function which is the necessary condition of Eq.1.

$$\begin{aligned}\bar{J}(U,c_1,\cdots,c_c,\lambda_1,\cdots,\lambda_n)&=J(U,c_1,\cdots,c_c)+\sum_{j=1}^{n}\lambda_j\left(\sum_{i=1}^{c}u_{ij}-1\right)\\&=\sum_{i=1}^{c}\sum_{j=1}^{n}\lambda_j\left(\sum_{i=1}^{c}u_{ij}-1\right)\end{aligned} \tag{3}$$

where λ_j $(i=1,2,\cdots,n)$ is the Lagrange multiplier of the constrained Eq.1. Carry on derivation operator for all the input parameters, and the necessary conditions for minimizing the objective function can be given by

$$c_i=\frac{\sum_{j=1}^{n}u_{ij}^m x_j}{\sum_{j=1}^{n}u_{ij}^m} \tag{4}$$

$$u_{ij}=\frac{1}{\sum_{k=1}^{c}\left(\frac{d_{ij}}{d_{kj}}\right)^{2/(m-1)}} \tag{5}$$

The clustering problem can be formulated as a nonlinear optimization problem with constraints. Using general methods are difficult to obtain the global optimal solution in the complex constrained conditions. The usual practice method is to use alternating iterative algorithm to optimize the allocation of matrix U and the clustering center V to get an approximate local minimum. The FCM algorithm adopts iterative Eq.3 and Eq.4 to achieve the minimization of the objective function, and then implement the fuzzy clustering of the data sets.

The implement of FCM algorithm can be summarized as follow

Step 1. Determining the clustering number C, the weighted index m, and random initializing the membership matrix $U^{(0)}$;

Step 2. Let $b=0,1,2,\cdots$;

Step 3. Computing the clustering center $V_i^{(b)}$ according to the membership matrix $U^{(b)}$ and Eq.4;

Step 4. Updating $U^{(b)}$ and $U^{(b+1)}$ as follow

(A) For $k=1,2,\cdots,n$ calculate

$$\begin{cases}I_k=\{i\,|\,1\leq i\leq c,d_{ik}=0\}\\ \bar{I}_k=\{1,2,\cdots,c\}-I_k\end{cases} \tag{6}$$

(B) Computing the membership function value of x_k, if I_k is null, calculate u_{ik} according to Eq.5, otherwise, let $u_{ik} = 0$ for all $i \in \bar{I}_k$ and set $\sum_{i \in I_k} u_{ik} = 1$.

(C) Comparing $U^{(b)}$ and $U^{(b+1)}$, if $\left\| U^{(b)} - U^{(b+1)} \right\| < \varepsilon$, stop the iterative process, otherwise, return the step 3 and continue the iterative process.

Although the FCM algorithm is an unsupervised classification algorithm, the weighted index m and the clustering center number c must be given before the iterative process. Therefore, the effectiveness of FCM clustering often can be transformed into the optimal number of classes and the weighted index decision problems. In order to obtain these two parameters reasonable value, the researchers proposed some improved method from two angles preferably to determining the optimal clustering number and the weighted index by using discriminant function, such as the probability distribution based discriminant function, fuzzy correlation discriminant function and subset hood measure discriminant function etc. This paper focuses on the initialization of the membership matrix, and the clustering number and the weight index are not discussed here. In the FCM algorithm, the membership matrix is often random initialized, and then using the iteration to minimize the objective function to complete the classification. As a result, the classification performance directly subject to the initialization membership matrix. Form the other view point, the FCM algorithm carry on the calculation for all the data set during the one iterative process, so the computational complexity is large. To obtain an effective method to improve FCM algorithm, hereby, we proposed a new initialization method for the membership matrix.

In one image, lots of the pixels are redundant. For a gray image with size 256×256, the number of pixel is 65536, but the gray level is 256. So we can sparse the image to initialize the membership matrix to improve the FCM algorithm. Let the data set is

$$X = \{x_1, x_2, \cdots, x_n\} \tag{7}$$

Using the down sampling method to spare the data set, which is given by

$$\bar{X} = \{x_1, x_2, \cdots, x_q\} \tag{8}$$

And then using FCM algorithm on the data set $\bar{X}$ to obtain an initial membership matrix $\bar{U}_{n \times q}$, where $q < n$ due to the sparse operation, so the dimension of $\bar{U}_{q \times c}$ must less than the membership matrix $U = (u_{ik})_{n \times c}$. It can reshape the initialization membership matrix $\bar{U}_{n \times q}$ as the initial membership matrix $U^{(0)}$ by inserting zero.

The data set spare method for initializing the membership matrix in the FCM algorithm can overcome the local point of the object function, and further improve the clustering performance. If the down sampling rate is high, the computational complexity would increase a little compared the traditional FCM algorithm.

Simulation and Discussion

The image in the simulation is obtained from the internet, which is a plant image with the resolution 1024*735 as shown in Fig.1. The iterative threshold segmentation method and the maximum variance threshold segmentation method are done in the simulation for comparison. The down sampling rate is 4. Using the data set after down sampling to determine the initial membership matrix after 100 iterative times, and then use the traditional FCM for the image segmentation to obtain the result which is shown in Fig.4. The iterative threshold segmentation method result is shown in Fig.2 and the maximum variance threshold segmentation result is shown in Fig.3. Simulation results show that, the improved FCM algorithm has better segmentation and effect calculation efficiency, and more importantly, this method can obtain automatic image segmentation result, at the same time, it can give the target image data structure (classification) prediction, the prediction results can be further used to guide the image classification and image understanding.

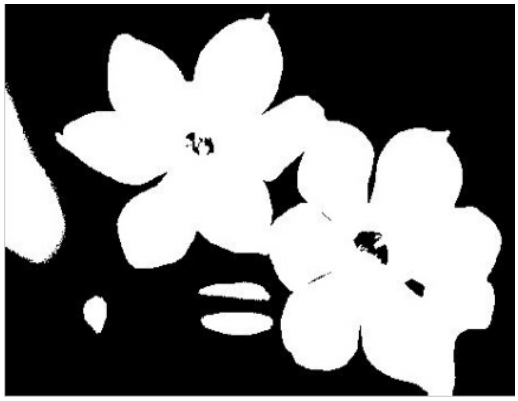

Fig.4 The improved FCM segmentation

Conclusions

This paper proposes an initialization method for the membership matrix in the FCM algorithm for image segmentation. The data set of image is down sampling to construct a new sparse data set, and the membership matrix is initialized by FCM on the sparse data set. This method can speed up the convergence rate of FCM and overcome the algorithm drop into the local minimum point of the objective function. As a result, the segmentation performance can be improved effectively.

[a]email: lnl1999@163.com

Keywords: Data Mining; Association Rule; Frequent Item Set; Bit Vector; Graph

Abstract. Because of the weakness of traditional Apriori algorithm, this paper presents an improved algorithm for mining frequent itemsets, which constructs bit vector and graph, the algorithm deletes node and the adjacent edges according to the number of node's edges, which need traverse graph to generate candidate itemsets and verify candidate itemset by bit vector. Experimental results show that the improved algorithm has better efficiency than Apriori algorithm.

Introduction

The concept of association rules was proposed by Agrawal in 1993[1], it is an important field in data mining. Mining association rule is one of the important content of data mining; it reflects the interesting association or correlation between data items. So it is widely used in many industries [2-3]. In this field, the most famous algorithm is Apriori, which is an iterative searching process, but Apriori algorithm need scan database many times to mine frequent itemsets, so the efficient of Apriori algorithm is very low in mining frequent itemset, especially in large scale data. So how to improve the efficiency to mine frequent itemset is search hot in data mining field. In recent years, many improved algorithms [4-6] based on Apriori algorithm have been proposed. The main limitation of these algorithms is the need to scan database many times to generate frequent item sets and to generate a huge amount of candidate item sets.

Any kind of information is able to be representing as graphs of graph databases, where changes in data can be possible for naturally accommodation [7].

Literature [8] algorithm scans database only once, and then construct the correlation graph, and discovering frequent item sets through search graph, but it need many times to traverse the graph to generate candidate itemset. And soon many improvements have been proposed [9], but the algorithm need search graph many times.

This paper puts forward the improved algorithm to overcome the shortcomings of above algorithms, the algorithm need scan database only once. The algorithm generates bit vector when scanning database and generate frequent 2-itemset by using bit vector, and then constructs the graph, and compute the count of node's adjacent edges set for each node. The algorithm generates candidate itemsets by traversing graph, the algorithm verifies frequent itemsets by bit vector logic operation. So the improved algorithm is high efficient in mining frequent itemsets.

Basic Concepts and Theorems

Definition 1 Let $D = \{T_1, T_2, \ldots, T_n\}$ be a transaction database, let I be all items of transaction database D, $I = \{I_1, I_2, \ldots, I_m\}$, therefore, any of T_j $(1 \le j \le n)$, then exist $T_j \subseteq I$. where T_i $(1 \le i \le n)$ is a transaction which contains a set of items in I. Let A be an itemset, if $A \subseteq T_j$, then T_j contains A.

Definition 2 Let X be an itemset, the support of X is the proportion of transactions in D which contain X, denoted as sup(X); if $sup(X) \ge min_sup$, min_sup is given by user, then X is a frequent itemset and X is called frequent K-itemset, otherwise X is a non-frequent itemset. The set of all frequent k-itemsets is denoted by L_k.

Definition 3 Let I_i be an itemset, the bit vector of Ii is denoted by V_i. All itemsets are sorted by lexicographic order.

Definition 4 If there exists an edge N_i--N_j in graph, then the count of the adjacent edge of node N_i plus 1.

Property 1 If frequent itemset L_k contains I_i, then node N_i has at least k-1 edges.

Proof: if k=2, frequent 2-itemset contains I_i, then there exists an frequent 2-itemset (I_i,I_j), according to the rule of constructing graph, there exists an edge N_i-N_j, node Ni has at least 1 edge.

If k>2, the count of frequent k-itemset's subsets which contains I_i has k-1 itemsets, then there exists k-1 edges in graph. So node N_i has at least k-1 edges.

Let min_sup be the minimum support threshold.

Property 2 if X is a frequent itemset, then any subset of X must be a frequent itemset; if X is not a frequent itemset, then any super set of X must be not a frequent itemset.

Mining frequent itemsets algorithm-the improved algorithm

A. Relation Knowledge of the Improved Algorithm

We construct bit vector when scanning the database. According to the definition of bit vector, we generate bit vector for each item in database D, for each item I_i ($1\le i\le m$), if T_j($1\le j\le n$) contains I_i, then $V_i[j]$ will be set to 1,otherwise $A_i[j]$ will be set to 0. So there have m bit vectors, each bit vector's length is the length of transaction; the improved algorithm adopts binary to storage 1 and 0 in order to reduce space overhead.

Then computing the number of 1s in bit vector V_i($1\le i\le m$), denoted as C_i, if $C_i \ge$min_sup, then item I_i is frequent 1-itemset. So we can easily generate frequent 1-itemset by bit vector.

Then generate candidate 2 itemsets according to frequent 1 itemset by vector product, any candidate 2 itemset $\{I_i,I_j\}$($sup(I_i)\le sup(I_j)$), let $B=V_i\&V_j$, if the number of 1s in B is greater than or equal min_sup, then $\{I_i,I_j\}$ is a frequent 2-itemset.

We construct the graph by using frequent 2-itemsets. The idea of constructing the graph is: if $\{I_i,I_j\}$ is a frequent 2-itemset, then draw an edge N_i-N_j in graph. We draw an edge in graph for each frequent 2 itemset. Then compute the count of each node's edges in graph, we construct the array A, A_i is the number of node N_i's edges.

According to the graph and node edges set A, we generate candidate itemsets. We generate candidate 3 itemset, according to property 1, we delete all nodes which the count of nodes edges is less than 2, then delete node and adjacent edges of the node, and then we continue to delete node and adjacent edges of the node until the number of node's edges is not less than 2. According to the method, we can generate candidate k itemsets. Traversing the graph in lexicographic order. According to this method, we generate all frequent itemsets.

B.Algorithm decription

The steps of the improved algorithm are follows:

Input:transaction database D, the minimum support min_sup;
Output:Frequent itemset FS_D;

```
FS_D = ∅;
for each transaction T_j in D
  begin
    if   T_j contains item I_i then   V_i[j]=1;
   else     V_i[j]=0;
generate frequent 1 itemset L_1 according to the number of 1s in bit vector;
sort items in L_1 by lexicographic order;
generate frequent 2 itemsets L_2 according to frequent 1 itemset;
foreach(∀{I_i,I_j} ∈ L_2)
      draw the edge N_i-N_j in graph G
for (each node N_i in the graph G) {
      if there exists the edge N_i-N_j   then
         add the number of the edges of N_i plus 1;
 }
int k=3;
while (G!=null)
{
```

```
        delete all nodes which the number of node's edges is less than k-1;
        generating candidate k itemsets in graph;
        generating frequent k itemsets by bit vector;
        add frequent itemset to FS_D;
        k++;
    }
```

C.Algorithm example

For the transaction database D, transaction set $T=\{T_1,T_2,\ldots T_9\}$, item set $I=\{I_1,I_2,I_3,I_4,I_5,I_6\}$,specific data is shown in Table 1, the minimum support threshold is 2.

Table 1 Transaction Database D

TID	Item
T_1	I_1,I_3,I_5
T_2	I_2,I_4,I_6
T_3	I_1,I_3,I_5
T_4	I_3,I_5,I_6
T_5	I_1,I_3,I_6
T_6	I_1,I_3
T_7	I_2,I_4
T_8	I_1,I_3,I_5
T_9	I_3,I_4,I_6

Table 2 Bit vectors on D

TID	V_1	V_2	V_3	V_4	V_5	V_6
T_1	1	0	1	0	1	0
T_2	0	1	0	1	0	1
T_3	1	0	1	0	1	0
T_4	0	0	1	0	1	1
T_5	1	0	1	0	0	1
T_6	1	0	1	0	0	0
T_7	0	1	0	1	0	0
T_8	1	0	1	0	1	0
T_9	0	0	1	1	0	1

(1) All bit vectors of transaction database D are shown in Table 2.

(2) We can easily get frequent 1-itemset, $L_1=\{\{I_1\},\{I_2\},\{I_3\},\{I_4\},\{I_5\},\{I_6\}\}$, then we easily get frequent 2 itemset $L_2=\{\{I_1,I_3\},\{I_1,I_5\},\{I_2,I_4\},\{I_3,I_5\},\{I_3,I_6\},\{I_4,I_6\}\}$ by L_1.

(3) Construct the graph according to the frequent 2 itemsets, and compute the number of each node's edges. The graph is shown is Fig 1.

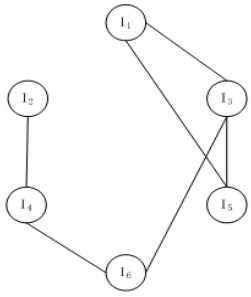

Fig 1. The graph

Construct the number of node, $A(I_1)=2$, $A(I_2)=1$, $A(I_3)=3$, $A(I_4)=2$, $A(I_5)=2$, $A(I_6)=2$.

(4) Generate candidate 3 itemsets. First, delete node N_{I2} and the adjacent edge N_2-N_4, then the number of node N_{I4}'s edges is 1, 1 is less than 2, so delete node N_{I4}, and delete the adjacent edge N_4-N_6, and then the number of node N_{I6}'s edges is 1, 1 is less than 2, then delete node N_6.so the graph has the remaining nodes$\{N_1,N_3,N_5\}$. Finally generate candidate 3 itemsets $C_3=\{\{I_1,I_3,I_5\}\}$.

(5) Because the number of each node's edges is less than 3, so candidate 4 itemsets is null. So the process of generating frequent itemset is over. Finally we get frequent itemset $FS_D=\{\{I_1,I_3\},\{I_1,I_5\},\{I_2,I_4\},\{I_3,I_5\},\{I_3,I_6\},\{I_4,I_6\},\{I_1,I_3,I_5\}\}$.

Analysis of algorithms

The improved algorithm need scan transaction database only once. The algorithm can generate bit vectors when scanning database. Time overhead depends on the length of transaction database, the average execution time is O(n); the number of the improved algorithm execution times by item decision, its average estimated execution time O (m*L), where m is the number of frequent itemset, L is the length of frequent itemset, its time complexity is much less than Apriori algorithm.

In order to verify the performance of the improved algorithm, this paper realized Apriori algorithm and the improved algorithm. Test database is mushroom database which is provided by Literature [10]. The experimental results obtained in the different support are shown in Fig 2.

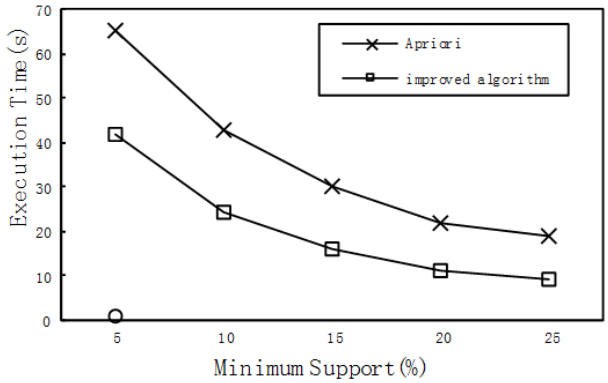

Fig 2. Performance comparison of two algorithms in different minimum support

Conclusion

This paper proposed the improved algorithm, the design idea of the improved algorithm is how to use bit vector and graph to generate frequent itemsets. The experimental results show that traditional algorithms take up too much memory; the improved algorithm uses bit vector of item to reduce memory overhead and delete useless node in generating candidate itemsets. The experimental results show that the improved algorithm has more obvious advantages compared to Apriori algorithm.

An Improved Otsu Image Segmentation Algorithm

Yanxue DONG[1, a]

[1]School of Information , Linyi University, Linyi, 276000, China

[a]email: dyxtmb@163.com

Keywords: Otsu; Segmentation; Threshold

Abstract. Otsu segmentation algorithm is one of the most successful algorithms in the field of image processing,However, it has drawbacks such as it is poor in dividing small object in images. This paper propose a improved Otsu algorithm based on weighted smooth histogram which can ensure the location of threshold point is more near to the valley point of the image and at the same time ensure the ensure between-class variance maximum.The results show that the improved Otsu algorithm can effectively accomplish segmentation for multimodal image, and get better segmentation results for images added Gaussian noise.

Introduction

Digital image is an important means for people to get, express, and convey information, statistics show that more than 80% of the information humans get is from the visual perception. Image processing technology can be divided into three levels: image processing, image analysis and image understanding. Image segmentation is an important step from image processing to image analysis, it is not only the basis of object expression but also the precondition of image analysis and understanding, the segmentation results will directly affect the quality of image analysis and image understanding.

The uncertainty of image information increases the difficulty of image segmentation, the traditional segmentation method can hardly meet the demand of image processing nowadays, how to get an segmentation more accurate is still a hot spot of current research.

Thresholding technique has been widely applied in object recognition, medical image processing and remote sensing image processing because it is simplicity and easy to implement. The key point of thresholding algorithms is to determine the optimal segmentation threshold, and the processing object of threshold technology is mostly gray image such as MRI image, infrared image and so on.

$F=[f(x,y)]_{M\times N}$ is used to describe a gray-scale image and its size is $M\times N$, L represents the maximum gray value, typically 255. Thresholding segmentation is to find the optimal threshold t^*, which make the following formulation established.

$$\bar{f}(x,y)=\begin{cases}0 & f(x,y)<t^*\\ 255 & f(x,y)\geq t^*\end{cases} \tag{1}$$

$\bar{f}(x,y)$ represent the image after segmentation. Obviously, the process of thresholding is equal to the process turning a gray image into a binarizied image.

The traditional Otsu algorithm has some drawbacks, for example, it can not divide small object from an image effectively, so this paper presents an improved Otsu algorithm which is called Ostu thresholding segmentation algorithm based on Weighted neighborhood. The results of this algorithm used in medical images shows that it can divied small object in the image effectively.

Traditional Otsu Theory

In 1979, the Japanese scholar dajin proposed an adaptive threshold segmentation algorithm base probabilistic statistical theory, which is called Otsu algorithm. This segmentation algorithm considered each gray scale in the image as a possible threshold which can divides the gray scale into two categories, calculate the variancec between classes for each classification in proper

order, select a gray scale value as the optical threshold which make the value of variance between classes maximum. The principle of the algorithm is shown as follows:

$F=[f(x,y)]_{M\times N}$ indicates a digital image with size $M\times N$, in which $f(x,y)$ represents the gray value of pixel(x,y), $f(x,y)\in G$ $G=\{0,1,\cdots,L-1\}$, L is the value of gray scale. $f(g)$ indicates The number of pixels which has gray value g, and then $h(g)$ which indicates the probability gray value g appears in the image is expressed as follows:

$$h(g)=\frac{f(g)}{M\times N}, g=0,1\cdots,L-1 \tag{2}$$

and the averages of probability distribution μ_r is:

$$\mu_r=\sum_{g=0}^{L-1} gh(g) \tag{3}$$

Assuming that threshold t divides an image into two categories, object region and background region, denoted by C_0 and C_1:

$$C_0=[0,\cdots,t], C_1=[t+1,\cdots,L-1] \tag{4}$$

and the priori probabilities of these two categories are expressed as follows:

$$P_0(t)=\sum_{g=0}^{t} h(g) \qquad P_1(t)=\sum_{g=t+1}^{L-1} h(g) \tag{5}$$

The averagets of these two categories is :

$$\mu_0(t)=\sum_{g=0}^{t} g\,h(g)/P_0(t) \qquad \mu_1(t)=\sum_{g=t+1}^{L-1} g\,h(g)/P_1(t) \tag{6}$$

obviously, $P_0(t)\mu_0(t)+P_1(t)\mu_1(t)=\mu_r$, $P_0(t)+P_1(t)=1$

According to the given threshold t, we can get within-class variance $\sigma_W^2(t)$ and between-class variance $\sigma_B^2(t)$ of C_0 and C_1

$$\begin{aligned}\sigma_W^2(t)&=P_0(t)\sigma_0^2(t)+P_1(t)\sigma_1^2(t)\\&=\sum_{g=0}^{t} h(g)(g-\mu_0(t))^2+\sum_{g=t+1}^{L-1} h(g)(g-\mu_1(t))^2\end{aligned} \tag{7}$$

$$\begin{aligned}\sigma_B^2(t)&=P_0(t)(\mu_0(t)-\mu_r)^2+P_1(t)(\mu_1(t)-\mu_r)^2\\&=P_0(t)\mu_0^2(t)+P_1(t)\mu_1^2(t)\end{aligned} \tag{8}$$

and

$$\sigma_r^2(t)=\sum_{g=0}^{L-1}(g-\mu_r)^2h(g)=\sigma_W^2(t)+\sigma_B^2(t) \tag{9}$$

Three criteria is given in [1] ,according which we can choose the best threshold, expressed as follows:

$$\lambda(t)=\frac{\sigma_B^2(t)}{\sigma_W^2(t)}, k(t)=\frac{\sigma_r^2(t)}{\sigma_W^2(t)}, l(t)=\frac{\sigma_B^2(t)}{\sigma_r^2(t)} \tag{10}$$

According to the formula (9), we can know, the summation of within-class variance $\sigma_W^2(t)$ and between-class variance $\sigma_B^2(t)$ is a constant, so the minimizing within-class variance is equivalent to maximizing between-class variance. That is why the Otsu algorithm is often referred to as the maximizing between-class variance method or minimizing within-class method. Generally, between-class variance $\sigma_B^2(t)$ is used as the segmentationf unction, that is the optical threshold t^* is as follows:

$$t^*=Arg\max_{0<t<L-1}\sigma_B^2(t)=Arg\max_{0<t<L-1}\{P_0(t)\mu_0^2(t)+P_1(t)\mu_1^2(t)\} \tag{11}$$

The image can be divided into two categories according to formula (1) and get $\bar{f}(x,y)$.

The classic Otsu method can be easily extended to the case of multi-threshold,suppose that there are $M-1$ thresholds which divide the image into M categories,denoted by $C_1,C_2,\cdots C_M$, the optical thresholds $\{t_1^*,t_2^*,\cdots,t_{M-1}^*\}$ are expressed as follows:

$$\left\{t_1^*, t_2^*, \cdots, t_{M-1}^*\right\} = Arg \max_{0<t_1<t_2<\cdots<L-1} \left\{\sum_{k=1}^{M} P_k \mu_k^2\right\} \tag{12}$$

Otsu method is simple, relatively easy to implement, and has better adaptability, so it is one of the most commonly used segmentation algorithms in engineering practice.

However, Otsu method supposes that the grayscale distribution of object region and background region in the images meet mixed Gaussian distribution which means less variance and very different mean. So Otus can not obtain appropriate segmentation threshold in many cases, when the histogram of an image has two peaks differ more, the threshold obtained by Otsu algorithm is more close to the peaks with larger variance, but not the valley point.

Improved Otsu algorithm

In literature[2], point histogram weighted ostu method is put forward, and in this paper, a smooth histogram weighted Otsu method is proposed combining with point histogram weighted Otsu method. This method weighted by adopting smooth histogram, not only uses information of threshold point in histogram, but also considers the neighborhood information of threshold point, and then makes the weighted more effective.

Suppose that the original histogram of an image is denoted as $h(g)$, we can calculate the smooth histogram using the following formula:

$$\bar{h}(g) = \left[h(g-m) + h(g-m+1) + \ldots + h(g) + h(g+1) + \ldots + h(g+m)\right] \tag{13}$$

Assuming $n = 2m+1$, n is the length of the smoothing filter, and it is generally odd.

The objective function of Otsu method weighted by smooth histogram is expressed as follows:

$$\xi(t) = \left(1 - \bar{h}(t)\right)\left(p_0(t)\mu_0^2(t) + p_1(t)\mu_1^2(t)\right) \tag{14}$$

The optical segmentation threshold:

$$t^* = Arg \max_{0<t<L-1} \xi(t) = Arg \max_{0<t<L-1} \left(1 - \bar{h}(t)\right)\left(p_0(t)\mu_0^2(t) + p_1(t)\mu_1^2(t)\right) \tag{15}$$

Formula (15) shows that Otsu method weighted by smooth histogram requires not only the probability of threshold point small, but also the probabilities in neighborhood of threshold point small, what can further ensure that the location of threshold point is valley point of the histogram.

Test results

Dividing Figure1 applying traditional Otsu algorithm and improved Otsu algorithm,segmentation results are shown in Figure2 and Figure3, thresholds get by the two algorithms is 148 and 71(where the length of the smooth filter is 7) ,easily know from Figure1 and Figure2 that improved Otsu algorithm is more effective in dividing small object than traditional Otsu algorithm.

Keywords: Radar Imaging; Compressed Sensing; 2-D Separable Sampling; 2-D Reconstruction Algorithm

Abstract. A radar compressed sensing imaging method with 2-D separable sampling is proposed in this paper. Instead of converting the radar imaging problem into two 1-D compressed sensing problem, we use the 2-D Separable Projections to solve it directly. Unlike the 2-D separable sampling in visible imaging, the range and azimuth which are the two dimensions of the radar imaging couple with each other. This Coupling increases the storage and computation in radar compressed imaging, therefore some de-coupling processing using in Range Doppler algorithm are adopted in the proposed method to construct the 2-D separable sampling data. Accordingly the two dimensional scene has been reconstructed with the proposed 2-D compressed sensing algorithms. Compared with conventional compressed sensing imaging methods, the new method has reduced the memory usage and complexity with imaging performance improvement.

Introduction

Radar imaging is an effective means to obtain information in all times and all weather conditions. Combined with the new emerging theory of compressive sensing (CS) technologies, the radar CS imaging can solve the acquisition, storing, processing and transmission problems caused by the demand for high-resolution [1][2].

Now, how to achieve better CS radar imaging has become a challenging problem. Alonso [3] proposed a novel imaging approach based on CS which is used to replace the traditional matched-filtering. It forms the basis of many 1-D CS imaging methods [4]. Some 2-D CS imaging methods are proposed in recent years [5]. Due to the existence of range and azimuth coupling, the memory usage and complexity of the recovery algorithms are very huge. Fang Jian [6] and Xiao Dong [7] proposed a 2-D CS imaging method which can solve this problem with traditional de-coupling operation. However, it needs to repeat the de-coupling operation in every iteration.

Some research results [6][8][9] suggested that the use of 2-D separable sampling observations in radar CS imaging can reduce both the memory usage and complexity in recovery algorithms. Meanwhile, since the de-coupling can be separated out alone with the two-dimensional separable observation, the repeat de-coupling operation can be avoided in the iterations.

In the proposed radar CS imaging method the imaging process is divided into two steps. In the first step, the Range Cell Migration Correction (RCMC) is processed in the Range Doppler domain, while the Secondary Range Compression (SRC) is conducted in the 2-D frequency domain. In the second step, the imaging scene is reconstructed by 2D recovery algorithm. The new method has reduced the memory usage and complexity with imaging performance improvement.

Signal models

Radar imaging system is a system that reconstructs the scene from the echoes. Supposing that the radar transmits LFM signals, then the echo signal of a point target can be written in equation(1).

$$S_0(t,\eta) = A_0 \cdot \exp\{j\pi K_r(t - 2\sqrt{R_0^2 + (v\cdot(\eta-\eta_0))^2}\ /\ c)^2\}\exp\{-j2\mathrm{m}\pi f_0\sqrt{R_0^2 + (v\cdot(\eta-\eta_0))^2}\ /\ c\} \quad (1)$$

Where (R_0, η_0) is the position of the point target; t is the fast time; η is the slow time; f_0 denotes the Carrier frequency; K_r is the range frequency modulation rate; c is the velocity of light and v is the carrier velocity. The pulse envelope and the antenna weighting are not considered here, so A_0 represents the scatter coefficient; m is depends on the imaging mode, if $\mathrm{m}=1$, it represents the forward-looking SAR imaging mode which proposed in [10], and if $\mathrm{m}=2$, it represents the normal side-looking SAR imaging mode. Considered that the imaging process is same，the side-looking SAR imaging mode here is enough.

2-D separable sampling data construction

The Traditional imaging algorithms will do some range compression which is achieved by matched filtering or compressed sensing before de-coupling operate. However it does not work here because the range chirp form is needed in the 2-D reconstruction. Thus the proposed method removes the effect of coupling on the range without range compression.

According to the stationary phase method, (1) can be translated to Range Doppler domain，

$$S_0(t, f_\eta) = A_0 \cdot \exp\{j\pi K_m (t - 2R_0 / c / D(f_\eta, v))^2\} \exp\{-j2\mathrm{m}\pi f_0 R_0 D(f_\eta, v) / c\} \exp(-j2\pi f_\eta \eta_0) \quad (2)$$

Where $D(f_\eta, v)$ is the Migration factor, with the analytic formulation(3).

$$D(f_\eta, v) = \sqrt{1 - c^2 f_\eta^2 / m^2 / v^2 / f_0^2} \quad (3)$$

The range frequency modulation rate has been modified to(4).

$$1 / K_m = 1 / K_r - 1 / K_{\mathrm{sec}} = 1 / K_r - 4cR_0 f_\eta^2 / m^3 / v^2 / f_0^3 / D^3(f_\eta, v) \quad (4)$$

Considering of the RCMC without range compression, the RCM is(5).

$$RCM = c \cdot t / 2 / D(f_\eta, v) \quad (5)$$

There are some differences from the traditional Range Doppler algorithm for that there is no range compression before RCMC. Generally, there are two methods to realize RCMC, one is interpolation, and the other is range scaling operation. Interpolation is used in the RCMC process here, the echo signal form changed.

$$S_1(t, f_\eta) = A_0 \cdot \exp\{j\pi K_m / D^2(f_\eta, v) \cdot (t - 2R_0 / c)^2\} \exp\{-j2\mathrm{m}\pi f_0 R_0 D(f_\eta, v) / c\} \exp(-j2\pi f_\eta \eta_0) \quad (6)$$

In view of equation(6), the range frequency modulation rate has changed again despite that these changes must be corrected effectively. Fortunately, these changes can be incorporated into Secondary Range Compression (SRC), meanwhile the SRC can be easily achieved by multiplying a phase in the 2-D frequency domain. According to the stationary phase method, equation (6) can be transformed to 2-D frequency domain

$$S_1(f_t, f_\eta) = A_0 \cdot \exp\{-j\pi D^2(f_\eta, v) f_t^2 / K_m\} \exp\{-j2\mathrm{m}\pi f_0 R_0 D(f_\eta, v) / c\} \exp(-j2\pi f_\eta \eta_0) \exp(-j4\pi f_t R_0 / c) \quad (7)$$

The phase function which is used to realizing the SRC can be represented as equation (8)

$$H(f_t, f_\eta) = (1 - D^2(f_\eta, v) f_t^2) / K_r - 4cR_{ref} f_\eta^2 / m^3 / v^2 / f_0^3 / D(f_\eta, v) \quad (8)$$

Where R_{ref} is the range of the scene center.

After the SRC, the influence of range by the coupling is eliminated completely. But the influence in azimuth frequency modulation rate still exists. Without the range compression, it can not be eliminated with the phase compensation in 2-D frequency domain. There are some methods can achieve it in spite of the difficulty. The easiest case is considering the azimuth frequency modulation rate as fix which equals to the azimuth frequency modulation rate in scene center on the condition that the scene is small enough. A harder one pre-compressed the range in 2-D frequency domain by multiplying a phase function initially， transformed to range Doppler domain and corrected the influence with another phase function sequently and transformed back to 2-D frequency domain and compensated the first phase function finally. These two methods can reduce the frequency modulation influence efficiently. The easier one is adopted here.

After transform to 2-D time domain, the echo signal gets the final form(9).

$$S_2(t,\eta) = A_0 \cdot \exp\{-j\pi K_r (t - 2R_0 / c)^2\} \exp\{-j2\mathrm{m}\pi f_0 \sqrt{R_{ref}^2 + v^2(\eta - \eta_0)^2} / c\} \tag{9}$$

The total echo signal can be written in the form of a double integral

$$S(t,\eta) = \int\int A(x,y) \cdot \exp\{-j\pi K_r (t - 2x / c)^2\} \exp\{-j2\mathrm{m}\pi f_0 \sqrt{R_{ref}^2 + v^2(\eta - y)^2} / c\} dxdy \tag{10}$$

2-D compressed sensing imaging

The 2-D compressed sensing is studied by some researchers. Rivenson [8] investigated the Compressed Imaging With a 2-D Separable Sensing Operator and deduced the reconstruction condition, Fang Yong [9] and Fang Jian [6] are applied the reconstruction algorithm in 2-D Separable Projections. All the work has shown that the 2-D compressed sensing especially the 2-D Separable Sensing can efficiently reduce the memory usage and complexity when applied to 2-D signal reconstruction. Recall (10), in fact, it can written as the 2-D Separable Sensing style. the discrete form of (10) can be written as (11)

$$S(m,q) = \sum_{n=1}^{N}\sum_{p=1}^{P} \exp\{-j\pi K_r \Delta t^2 (m-n)^2\} A(n,p) \cdot \exp\{-j2\mathrm{m}\pi f_0 \sqrt{R_{ref}^2 + v^2 \Delta\eta^2 (q-p)^2} / c\} \tag{11}$$

Rewritten it in matrix form

$$S = \Phi_r A \Phi_a^T \tag{12}$$

Where S is a $M \times Q$ matrix; Φ_r is a $M \times N$ matrix; Φ_a is a $Q \times P$ matrix; with

$$\Phi_r(i,j) = \exp\{-j\pi K_r \Delta t^2 (i-j)^2\} \tag{13}$$

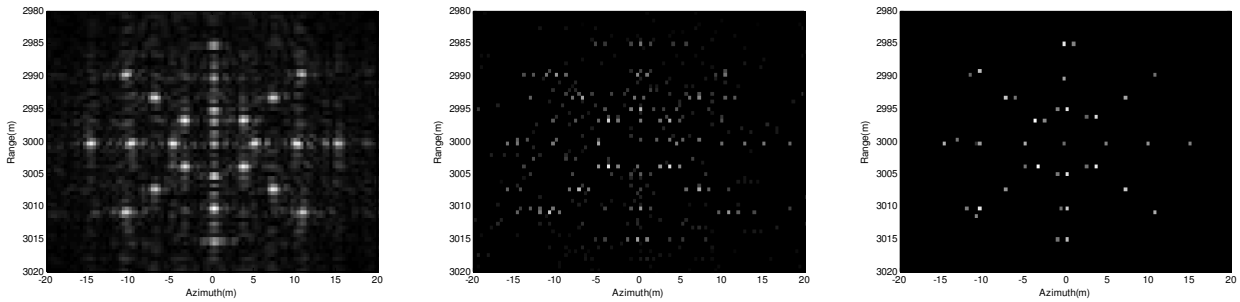
$$\Phi_a(i,j) = \exp\{-j2\mathrm{m}\pi f_0 \sqrt{R_{ref}^2 + v^2 \Delta\eta^2 (i-j)^2} / c\} \tag{14}$$

So the scenes A can be reconstruction by the echo S using 2-D compressed sensing algorithm.

It is noteworthy that there is no coupling with the sampling matrix Φ_r and Φ_a. In other words, this is a 2-D Separable Sensing problem. Benefited from the Separable Sensing Operator and 2-D compressed sensing algorithm, the memory usage and complexity of reconstruction algorithm is reduced. Owe to 2-D joint reconstruction, the imaging performance will be improved effectively as well.

Experimental results

The simulation is conducted in three imaging methods, the first one is the traditional matched filter imaging with RD algorithm, the second one is the compressed sensing imaging using two 1-D reconstruction algorithms and the third one is the compressed sensing imaging using 2-D reconstruction algorithm which proposed in this paper. The targets are uniformly distributed on a circular that the Radius of the circle is growing in a step of 5m. The experiment is imaging with 25% data and results are shown in Figure1.



(a) Matched filter (b) 1-D reconstruction algorithm (c) 2-D reconstruction algorithm

Fig.1. The experimental results

As expected, the 2-D separable sampling compressed sensing with 2-D reconstruction algorithm obtained the best performance even with partial data. The reason for this is that the 2-D signal in

2-D reconstruction algorithm is much sparser than the 1-D signal in 1-D reconstruction algorithm. It is worth to note that 2-D separable sampling greatly reduces the memory usage and the 2-D reconstruction algorithm can reduced the reconstruction complexity efficiently in CS imaging. So the new method has several advantages over traditional CS imaging methods in performance of both memory usage and reconstruction complexity.

Conclusion

Based on 2-D separable sampling and 2-D reconstruction algorithm, a 2-D separable compressed sensing radar imaging method is proposed. The construction method of 2-D separable sampling data is investigated and an imaging model using two-dimensional reconstruction algorithm to process these separable sampling dates is showed. Compared with traditional methods, the proposed two-dimensional separable sampling method can effectively reduce the memory usage and complexity with imaging performance improvement.

Keywords: MMSE channel estimation, QC-LDPC, OFDM;

Abstract. An orthogonal frequency division multiplexing (OFDM) is one of the effective techniques used in wireless communications. In OFDM systems, channel impairments due to multipath dispersive wireless channels can cause deep fades in wireless channels. The OFDM receiver also requires an accurate and computationally efficient channel state information when coherent detection is involved. Therefore, it needs a good robust estimation method of the channel in wireless communication for OFDM systems. And one of these channel estimation methods is minimum mean square error (MMSE) channel estimation. MMSE channel estimation one most used method in OFDM systems. In this work we enhanced robustness of MMSE channel estimation by using it in base of quasi-cyclic low density parity check (QC-LDPC) coded OFDM system.

Introduction

The OFDM is mostly used in wideband digital communications for splitting a high-rate datastream into a number of lower rate streams that are transmitted simultaneously over a number of subcarriers for easy transmission. The OFDM technique is applicable in digital terrestrial multimedia broadcast (DTMB) [1], digital subscriber line (DSL) broadband internet access, wireless networks, long term evolution (LTE) [2-3], and 4G mobile broadband communications [3]. In OFDM system, the transmitter modulates the message bit sequence into phase shift keying (PSK) / quadrature amplitude modulation (QAM) symbols, performs inverse fast fourier transform (IFFT) on the symbols to convert them into time-domain signals, and sends them out through a wireless channel. In order to avoid intercarrier interference (ICI) which caused by multipath fading channel. The OFDM system inserts cyclic prefix (CP) at the transmitter to provide high bandwidth efficiency and high wireless data transmission.

Channel estimation is an indispensable part of the OFDM system, which performance has a significant impact on system performance. MMSE channel estimation is one of the most used estimation methods in OFDM system. MMSE channel estimation outperforms the other estimator least square (LS) in [4-5]. MMSE estimator uses prior information about the channel statistics. In [6] MMSE channel estimation is modified for effective estimation of the effects of channel impulse response variations. Proposed approach has better bit-error-rate (BER) performance than conventional approaches for signal to noise rate (SNR) varying from 3 to 8 dB by using low-density parity check coded single-input single output OFDM system in [7]. Also a configurable high throughput QC-LDPC decoder architecture based on layered message described in [8]. In this work we have shown MMSE channel estimation in base of QC-LDPC coded OFDM system.

System Description

Considering OFDM system with size M OFDM symbol, the k^{th} block of OFDM symbols is expressed as $\tilde{\mathbf{S}}_M(k)=\left[\tilde{S}_1(k),\cdots,\tilde{S}_M(k)\right]^T$, where $(\cdot)^T$ denotes the operator of transpose. After inverse fast fourier transform

$$\mathbf{s}_M(k)=\left[s_1(k),\cdots,s_M(k)\right]^T=\mathbf{F}_M^H\tilde{\mathbf{S}}_M(k) \tag{1}$$

where $\mathbf{F}_M$ is the size M FFT matrix with entries $\mathbf{F}_M(m,n)=(1/\sqrt{M})e^{j2\pi mn/M}$

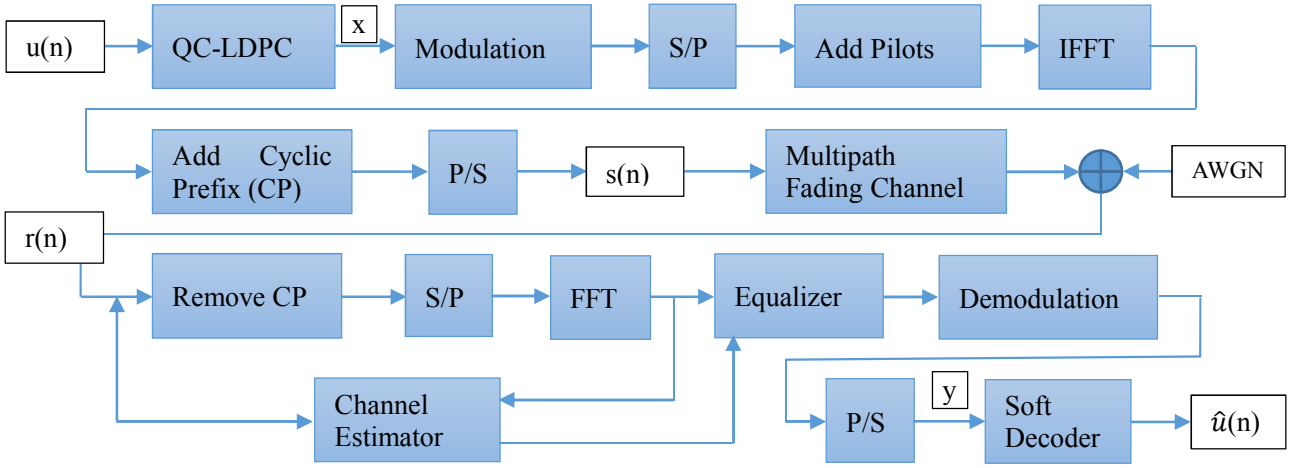

Fig. 1. Pilot sequence based single input single output OFDM system architecture

n figure 1 we showed simplified architecture from [7]. Let *Sdata=S(Id)* is a data symbols and *Spilot=S(Ip)*, *Id* and *Ip* are the vectors containing the indices of the subcarriers reserved for data and pilots respectively. The output of IFFT is

$$s(n) = IFFT(S) = \sum_{k=0}^{N=1} S(k) e^{i\frac{2\pi kn}{N}} \quad n = 0,1,...,N-1 \tag{2}$$

After CP adding into OFDM symbol through inserting the end *Lg* subcarrier to the start as per the following equation:

$$s(P) = \begin{cases} s(N - Lg + P) & P = 0,1,...,Lg-1 \\ s(Lg - P) & P = Lg, Lg+1,...,Lg+N-1 \end{cases} \tag{3}$$

where *Lg* is the length of the cyclic prefix, we assume that the cyclic prefix in each OFDM symbol is longer than the maximum delay spread. The received signal at the receiver can be expressed as:

$$r(n) = e^{i\frac{2\pi\omega n}{N}} \sum_{k=0}^{K-1} h(k)s(n) + w(n) \tag{4}$$

Where ω is the carrier frequency offset (CFO) normalized to the OFDM subcarrier spacing, $h(k)$ represents the kth tap channel impulse response, K is number of taps in the channel, and w(n) is a complex AWGN sample.

Quasi-Cyclic LDPC codes

According to [8] LDPC code is: $Hx = 0_{M\times 1}$; in (galious field) GF(2), where x is the *N*-dimensional binary-valued data vector, $0_{M\times 1}$ denotes an *M*-dimensional all-zero vector, and *H* is a sparse binary-valued $M \times N$ parity check matrix. QC-LDPC codes are described by a $M_p \times N_p$ LDPC matrix prototype H_p. The parity check matrix H in $Hx = 0_{M\times 1}$ is constructed from H_p by replacing each entry by $Z \times Z$ cyclic-shift matrices are defined as $P^c = \prod_{i=1}^{c} P^1$ (for *c*>0) with

$$[P^1]_{i,j} = \begin{cases} 1, & (i \bmod Z) + 1 = j \\ 0, & otherwise \end{cases} \tag{5}$$

$P^0 = I_z$, and $P^- = 0_{z\times z}$. Here entries of H_p satisfy $[H_p]_{m,n} < Z(\forall m,n)$.

Quasi -Cyclic LDPC decoding

The parity checks in $Hx = 0_{M\times 1}$ can be represented as a bipartite graph consisting of N variable nodes and M check nodes. Variable nodes are associated with transmitted bits x_n, $(n = 1,2,...,N)$.

The *m*th parity check node is connected to the *n*th variable node if $H_{m,n}=1$. LDPC decoding are represented as message passing (MP) on the bipartite graph and it consists of two phases. In the first phase, all messages from the variable to the check nodes (denoted by Q-messages) are computed with the aid of log-likelihood ratios (LLRs):

$$L_n \triangleq \log\left(\frac{P[x_n=0\,|\,y]}{P[x_n=1\,|\,y]}\right), \quad n=1,2,...,N \tag{6}$$

where y denotes the channel observation. In the second phase, all messages from the check to the variable nodes (denoted by R-messages) are computed. Both phases are repeated until $Hx=0_{M\times 1}$ is satisfied (i.e., the algorithm converges to a valid code-word) or a maximum number of iterations *I* has been reached.

Channel estimation

Suppose there are N_{pil} pilots in frequency domain signal at transmitter, denoted by $\tilde{S}=\left[\tilde{S}_{pil}(1),\cdots,\tilde{S}_{pil}\left(N_{pil}\right)\right]$. The corresponding frequency domain symbol in the receiver is $\tilde{R}=\left[\tilde{R}_{pil}(1),\cdots,\tilde{R}_{pil}\left(N_{pil}\right)\right]$ and **N** noise vector frequency domain. With the LS channel estimation, the channel frequency response is

$$\tilde{\mathbf{H}}_{LS}=\left[\frac{\tilde{R}_{pil}(1)}{\tilde{S}_{pil}(1)},\cdots,\frac{\tilde{R}_{pil}\left(N_{pil}\right)}{\tilde{S}_{pil}\left(N_{pil}\right)}\right] \tag{7}$$

According to [9], the MMSE channel estimation parameters as follows: $\widetilde{\mathbf{H}}_{\mathbf{LS}} \triangleq \widehat{\mathbf{H}}$; R_{HH} is autocorrelation of true channel $\mathbf{H}$; $R_{H\hat{H}}$ is the cross-correlation matrix between the true channel vector $\mathbf{H}$ and channel estimate vector $\hat{\mathbf{H}}$ in the frequency domain; $R_{\hat{H}\hat{H}}=E\left\{\hat{\mathbf{H}}\hat{\mathbf{H}}^{H}\right\}=R_{HH}+\frac{\sigma_N^2}{\sigma_S^2}\mathbf{I}$ is autocorrelation matrix of $\hat{\mathbf{H}}$. The MMSE channel estimation is:

$$\tilde{\mathbf{H}}_{MMSE}=R_{H\hat{H}}R_{\hat{H}\hat{H}}{}^{-1}\hat{H}=R_{H\hat{H}}(R_{HH}+\frac{\sigma_N^2}{\sigma_s^2}I)^{-1}\hat{H} \tag{8}$$

where σ_N^2 is frequency domain N noise variance, σ_S^2 frequency domain signal variance and **I** is identity matrix.

Let $\tilde{\mathbf{H}}_{pil}=\tilde{\mathbf{H}}_{MMSE}$ and $\mathbf{F}_{pil}$ denote FFT matrix at the pilot, which is constituted by first *L+1* columns of $\sqrt{M}\mathbf{F}_M$, and selects only the rows corresponding to the pilot carriers. Therefore, the channel impulse response can be expressed as

$$\mathbf{h}_{pil}=\frac{1}{M}\mathbf{F}_{pil}^{H}\tilde{\mathbf{H}}_{pil} \tag{9}$$

$\mathbf{h}_{pil}$ is the knowledge of channel time-domain attenuations afforded by pilot.

Simulation Results

During simulation process, each OFDM symbols occupied 64 subcarriers, 48 data and 16 pilot subcarriers with 16 CP. QAM 16 and QAM 64 modulations are used, and the simulation results are indicated in Fig.2 and Fig.3. We have evaluated the performance of MMSE channel estimation in OFDM systems and MMSE channel estimation in QC-LDPC coded OFDM systems. Furthermore we have compared the MMSE in traditional OFDM and in QC-LDPC coded OFDM systems over Rayleigh fading channel of 4, 16 and 36 taps. As the channel order is different for different environmental conditions and also with QAM 16 and QAM 64 modulations, these changings increase the adversity effects of the environment. It is clear that MMSE in QC-LDPC coded OFDM outperforms in different channel taps.

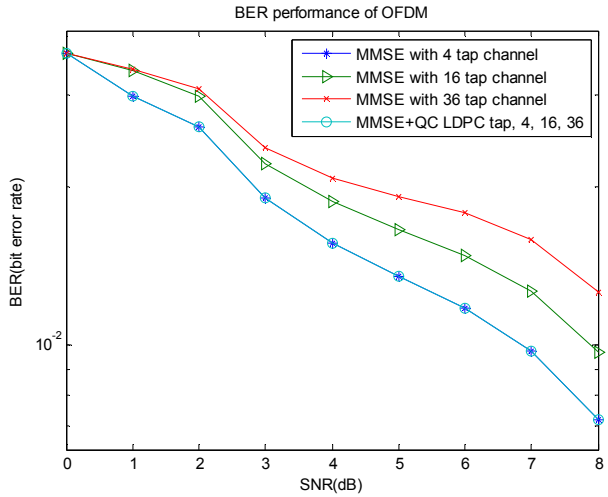

Figure.2 BER vs. SNR, QAM 16 modulation for channel tap 4, 16 ,36

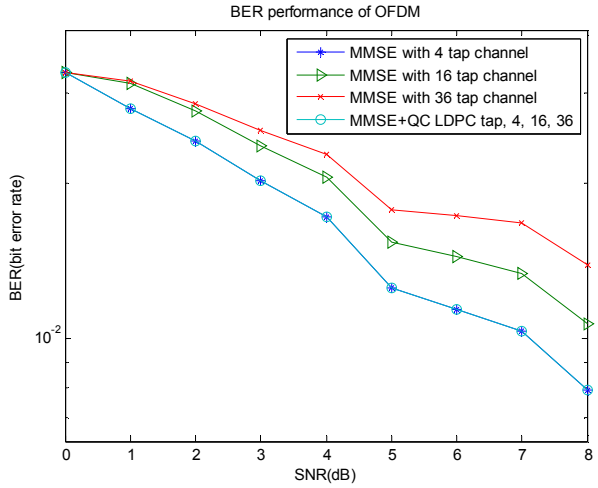

Figure.3 BER vs. SNR, QAM 64 modulation for channel tap 4, 16 ,36

Conclusion

In this paper we simulated MMSE in QC-LDPC coded OFDM systems over Rayleigh fading channel with 4, 16 and 36 taps. The QC-LDPC with ½ rate 5184 bits by QAM16 and QC-LDPC with 2/3 rate 5184 bits modulated by QAM64. It is observed that the performance of the these simulations MMSE in QC-LDPC coded OFDM system stays stable with increase in length of channel taps, however MMSE in OFDM system shows a significant performance degradation with an increase in channel taps.

Keywords: Regional energy; Image fusion;NSCT

Abstract. A novel fusion algorithm based on Nonsubsampled Contourlet Transform (NSCT) is proposed, according to the characteristics of infrared and visible images. Firstly, the registered infrared and visible images from the same scene were transformed by NSCT transforms; then the low frequency coefficient is fused by the combination of local energy and normalised correlation matrix, the high frequency coefficient fusion is fused by regional energy matching with regional variance; finally, the target image is obtained by performing inverse NSCT transforms. experimental results indicate that the proposed algorithm can effectively get more detail information and the fusion performance is dramatically better than traditional fusion methods.

Introduction

Due to the different imaging mechanism and bands between different sensors, images of the same scene obtained by different sensors have complementary and redundant informations. Image fusion refers to the information processing of synthesizing an image or image sequence information about a specific scene obtained by two or more sensors at the same time or at different times[1] in order to generate new information about the scene. The mechanisms of visible light and infrared imaging sensors are different: Infrared imaging sensors generate images by using thermal radiation energy of the target scene; thus they have a certain ability to penetrate smoke, fog, etc. and a strong ability to recognize disguise. However, they are not sensitive to detailed changes of the scene and have low image resolution. Visible light imaging sensors generate images by using the reflectivity of light; thus they have a good spatial resolution and can well describe the environmental information of a specific scene. However, they can easily be influenced by light intensity and weather. By fusing images generated by infrared and visible light, we can make full use of their complementary information and improve the recognition and clarity of infrared targets in order to gain fusion images better for the observers to get an overall cognition of the scene.

In recent years, scholars have proposed a lot of methods to fuse infrared images and visible light images, mainly including: the method based on multi-resolution analysis, the method based on weighting a single pixel and the method based on regional segmentation[2][3].Because constructing a new multi-resolution structure is difficult and it may not be able to adapt to practical application, researches on fusion rules have always been the focus of study of such methods[4].At present, researches on fusion rules mostly focus on the fusion of high frequency coefficient, and the low frequency coefficient fusion methods mainly include the average method, ‘take the biggest’ method[5], and etc. Although to some extent these low frequency fusion rules have improved the efficiency of the algorithm, they have reduced the contrast ratio of these fusion images, which make the loss of some useful information in the source images.

According to the above situation, in order to make the details of the fusion image have better performance and further facilitate interpretation personnel and computers, this paper puts forward a kind of infrared and visible light fusion method in the NSCT domain based on local energy and the normalized correlation moments.

NSCT Transformation

Non-sampling Contourlet Transformation (NSCT) is proposed based on Contourlet Transformation. It not only inherits the multi-scale and multi-directional characteristics of Contourlet Transformation and good local features of space and frequency, which make it able to capture and track the important geometric features of images better, but also has the characteristic of translational invariance[6][7].Non-sampling Contourlet Transformation is also made up of two parts: Non-subsampled Pyramid(NSP) decomposition and Nonsubsampled Directional Filter Bank(NSDFB),which ensure the NSCT transformation decomposition characteristics of multi-scale decomposition and multiple directions. In the process of NSCT Transformation decomposition, there are no 'up and down' samples, and all the subgraphs of the decomposed are of the same size as the original images so as to make the NECT Transformation has the feature of translational invariance. Fig.1.(a)and Fig.1.(b)give the NSCT filter bank structure and frequency decomposition respectively.

Fusion Methods of Infrared and Visible Light Images Based on NSCT Transformation

Fusion Rules of Low-frequency subband coefficients

After decomposition of the source image by the NSCT transformation, the low frequency subband image inherits the characteristics of the source image as a whole, determines the image contour [7] and occupies most of the image energy, which reflects how much information the image contains. Therefore, from the perspective of energy in the low frequency rules, this paper first calculates the contribution ratio of each pixel of low-frequency to the window as below:

$$F^X(x,y)=\begin{cases}\left|\dfrac{C^X(x,y)-\mu(x,y)}{\sigma_{xy}}\right| & \sigma_{xy}\neq 0\\ \dfrac{1}{M\times N} & \sigma_{xy}=0\end{cases} \tag{1}$$

Wherein, $M\times N$ refers to the size of the window, σ_{xy} refers to the deviation of each corresponding pixel of the window, $C^X(x,y)$ refers to the pixel value of each point in the window, $X=A,B$; and $\mu(x,y)$ refers to the average pixel value in the window. The energy of the local area window at the center of the low-frequency part is as below:

$$E_{LX}=\sum_{(x,y)\in K}F^X(x,y)\cdot\left|C^X(x,y)\right|^2 \tag{2}$$

Wherein, $K=M\times N$ refers to the regional window, $C^X(x,y)$ refers to the low frequency coefficient after the decomposition of the source image by the NSCT transformation. Energy difference defined by the normalization factor is $\Delta=\left|E_A(x,y)-E_A(x,y)\right|$, wherein

$$E_A(x,y)=\frac{E_{LA}(x,y)}{E_{LA}(x,y)+E_{LB}(x,y)} \tag{3}$$

$$E_B(x,y)=\frac{E_{LB}(x,y)}{E_{LA}(x,y)+E_{LB}(x,y)} \tag{4}$$

The threshod value is $T_1 \in (0.04, 0.1)$, so low frequency coefficients are fused according to the following fusion rule:

$$\begin{cases} D_{FL}(x,y) = C^A(x,y) & \Delta \geq T_1, E_A(x,y) \geq E_B(x,y) \\ D_{FL}(x,y) = C^B(x,y) & \Delta \geq T_1, E_A(x,y) < E_B(x,y) \\ D_{FL}(x,y) = E_A(x,y) \cdot C^A(x,y) + E_B(x,y) \cdot C^B(x,y) & \Delta < T_1 \end{cases} \tag{5}$$

Wherein, $D_{FL}(x,y)$ refers to the low-frequency coefficient of the point (x,y) in this fusion image.

Fusion Rules of High-frequency Bandpass Directional Subband Coefficient

As there is more energy at the corresponding image edges and other detailed parts reflected by the high efficiency coefficient and regional variance reflects the deviation degree of the pixel gray value to the average value in the area, the greater the variance, the greater difference between each pixel in the region and the more information this region contains. In this paper, the high-frequency coefficient fusion rules construct high-frequency coefficient of fusion images by constructing regional energy compatibility and taking the largest variance in this region.

The definition of regional energy matching degree is as below:

$$M_{A,B}(x,y) = \frac{\left| 2 \sum_{(x,y) \in K} w(m,n) \left| C_{j,l}^A(x+m, y+n) C_{j,l}^B(x+m, y+n) \right| \right|}{E_{j,l}^A(x,y) + E_{j,l}^B(x,y)} \tag{6}$$

Wherein, $E_{j,l}^X(x,y)$ refers to the regional energy of the $M \times N$ window centering on the (x,y) point at scale 1 section J and the definition is as below:

$$E_{j,l}^X(x,y) = \frac{1}{MN} \sum_{m=-(M-1)/2}^{(M-1)/2} \sum_{n=-(N-1)/2}^{(N-1)/2} w(m,n) \left(C_{j,l}^X(x+m, y+n) \right)^2 \tag{7}$$

$C_{j,l}^X, (X = A, B;\ j,l = 1,2,3\cdots)$ refers to the high frequency subband coefficients of the source image X at scale 1 section J after the decomposition by the NSCT. $w(m,n) = [1,2,1;2,4,2;1,2,1]/16$ refers to the window mask.

If $M_{A,B}(x,y) \geq \alpha$, then the weighted averages used to carry out the fusion, and the coefficient after the fusion is:

$$C_{j,l}^F(x,y) = q_A C_{j,l}^A(x,y) + q_B C_{j,l}^B(x,y) \tag{8}$$

Wherein, q_A, q_B refers to the self adaptive adjustment factor:

$$\begin{cases} q_A = \dfrac{E_{j,l}^A(x,y)}{E_{j,l}^A(x,y) + E_{j,l}^B(x,y)} \\ q_B = \dfrac{E_{j,l}^B(x,y)}{E_{j,l}^A(x,y) + E_{j,l}^B(x,y)} \end{cases} \tag{9}$$

If $M_{A,B}(x,y) < \alpha$, then the regional variance is defined as:

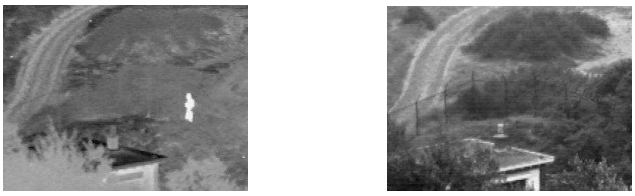
$$V_{j,l}^X(x,y) = \frac{1}{(M-1)(N-1)} \sum_{m=-(M-1)/2}^{(M-1)/2} \sum_{n=-(N-1)/2}^{(N-1)/2} \left| C_{j,l}^X(x+m, y+n) - \bar{C} \right|^2 \tag{10}$$

$$C_{j,l}^F(x,y) = \begin{cases} C_{j,l}^A(x,y) & if \quad V_{j,l}^A(x,y) \geq V_{j,l}^B(x,y) \\ C_{j,l}^B(x,y) & if \quad V_{j,l}^A(x,y) < V_{j,l}^B(x,y) \end{cases} \tag{11}$$

Simulation, analysis and evaluation

In order to verify the validity and effects of the algorithm, this paper uses MATLAB7.0 to carry out the simulation experiment, and compare the algorithm used in this paper with fusion rules like the commonly used ‘take the biggest’ method, the weighted average method and ‘take the biggest regional variance’ method, and etc. And the experimental data use two sets of images produced by

infrared and visible light. Figs. 2 are 'UN Camp' visible and infrared sequence diagrams provided by the Holland TNO Ergonomics Institute. The grey level of this image is 256, and the size is 360×270.



(a) Infrared Image (b) Visible Light Image

Fig.2. Infrared and Visible Light Images

In the simulation experiments, every fusion algorithm is taken out in the NSCT domain, using decomposition layer 3, and in accordance with the order from the senior to junior, the numbers of directional decomposition are 2, 4 and 8 separately. Scale decomposition filter group adopts '9-7', and directional decomposition filter group uses 'pkva'. The size of the neighbour is taken as 3×3,and T_1 taken as 0.05, α as 0.7.Definitions of the fusion rules are as follows:(1) For the low-frequency coefficients, take the average method, and for the high-coefficients, the 'take the largest regional variance' method;(2) For the low-frequency coefficients, take the average method, and for the high-frequency coefficients, the 'take the biggest absolute value' method;(3) For the low-frequency coefficients, take the 'weighted average' method, and for the high-coefficients, the 'take the biggest regional variance' method;(4)For the low-frequency coefficients, take the 'weighted average energy' method, and for the high-frequency coefficients, the 'take the biggest absolute value' method;(5)Fusion rules in this paper: The low-frequency coefficients are based on local energy and normalized correlation moments; for the high-frequency coefficients, the 'take the biggest regional variance with some regional energy matching degree' method is taken.

Fusion Rule (1) Fusion Rule (2) Fusion Rule (3) Fusion Rule (4) Fusion Rule (5)

Fig.3. Fusion Images Produced by Different Fusion rules

From a subjective visual perception, we can find that all these five ways can better keep the important information of the source image and integrate the features of the source image. And the fused image can better extract the scene information of the visible light images and the target information of infrared images. However, the contrast of the fusion result goals with the scene is small, which is due to the use of a simple average method to the low-frequency images. On the other hand, the contrast of fusion result details produced by using the fusion rules proposed in this paper is large, and the scene information is more abundant.

In order to evaluate the performance of different fusion methods of infrared and visible light images, this paper adopts the information entropy[9] , the standard deviation[9], the average gradient[9] and the mutual information[9] as the image fusion evaluation indexes. The bigger the entropy, the richer informations the image contains, and the better the quality of the fusion is. Standard deviation reflects the degree of dispersion of grey intensity of the image to the average grey value. If the standard deviation is large, then the greyscale of the image disperses; the image contrast is great, and more information can be seen. Average gradient not only reflects the clarity of the image, but also reflects the tiny contrasts in the image. The greater the average gradient, the more contrast details there are, and the higher degree of information retention. The greater amount of mutual information, the more information we can get from the source image. The comparison results are as follows:

Table.1. The Comparison of Performance of Different Fusion Algorithms Between Infrared and Visible Light Images

Evaluation Index	Ways of Fusion				
	Fusion Rule(1)	Fusion Rule(2)	Fusion Rule(3)	Fusion Rule(4)	Fusion Rule(5)
Information Entropy	6.3404	6.5926	6.6359	6.7241	6.8399
Standard deviation	24.7854	26.8564	27.1457	29.3654	29.5147
Average Gradient	5.3475	6.0214	5.4712	6.1243	6.1512
Mutual Information	1.0780	1.0990	1.3593	1.4628	1.4721

By analyzing the data in Table 1, it is not difficult to find that the fusion method proposed in this paper is superior to other fusion methods in the evaluation indexes information entropy and mutual information, indicating that the differences between the source image and the fusion image are small. Moreover, the average gradient of the fusion image is better than other methods, which shows that the tiny details of the image are better.

Conclusions

As a new kind of multiscale geometric analysis tool, NSCT has shown much superiority in the field of image fusion. Based on this, this paper presents a new fusion method in which low-frequency normalized moment is based on local energy and high-frequency coefficient uses the 'take the biggest regional variance in terms of regional energy matching' in the field of NSCT. This method has solved the problem that traditional average method and 'take the biggest' method are likely to reduce the contrast of the fusion images. Moreover, experimental statistics have further proved that the method proposed in this paper has a better visual effect and an objective evaluation indicator of quantity. However, when there are more NSCT decomposition levels and running codes, the method proposed in this paper remains to be improved.

Keywords: Text Extraction; Mathematical Morphology; Skeleton; Document Image Process

Abstract. This paper presents a new method to achieve effective text extraction using mathematical morphology. Firstly, the document is segmented and divided into several parts based on the layout. And then, every part is dilated to big connected regions, whose biggest skeleton will be extracted and serve as a structure element(SE). Finally, a proposed region- concatenated operation with the SE will be employed, whose result can be the input of subsequent OCR system. Experimentally, the proposed method is robust to noise, the text orientation, font style and size, language and layout.

I.Introduction

Recent years, the text region extraction from document images has many practical meanings and provides many useful applications in image searches, optical character recognitions and compressions.Traditionally, methods of text extraction are commonly subdivided into three groups: top-down, bottom-up and hybrid techniques.

Bottom up techniques[1] based on connected components analysis to use merging and grouping from the thinnest elements. They do not make assumptions on size and about page layout，but they are computationally expensive and rely on the use of appropriate thresholds； Top-down techniques[2] are fast and efficient but the efficiency depends on priori knowledge .

Most methods do not fit into any of the two categories above were called hybrid.Typically, some methods based on edge information[3]have been proposed. But its process objective is limited that only Latin character can be handled. A method[3]subdivides the document into many small overlap column elements, then carries out a histogram analysis to connect them. It is able to work on low-resolution and is robust against skew, fast and very flexible. Unfortunately, it requires uniform background and approximately horizontal text. In [4], it proposes a mixed method which is independent from text orientation and is able to handle inverse text while its performance, unfortunately, depends on the quality of connected components strongly.

In this paper, a morphological method which focuses on the document's structure provides a new way to extract the text. The algorithm is straightforward in comprehension and processing while it is also robust against text orientation, font style and size, language . The algorithm is also fast and effective because of less multiplication, division.

II. Morphological Transforms

Mathematical morphology is a well-known technique based on set theory and lattice lgebr--a. It often includes many different standard morphological operations namely dilation, erosion, opening, closing etc. Structure element (SE) usually plays an important role in these transforms.

2.1 basis of MM transforms

The two most fundamental morphological operations are dilation and erosion. Erosion is used to delete the thin strokes and cause objects to shrink, Dilation is used to fill holes and narrow gulfs in objects and increases the object size. In gray scale they are defined by follows:

$$[\varepsilon_B(f)](x) = \min_{b\in B} f(x+b) \qquad (1) \qquad [\delta_B(f)](x) = \max_{b\in B} f(x+b) \qquad (2)$$

Opening (closing) is sequential combination of erosion (dilation) and dilation (erosion) with SE. The opening will remove all the pixels in the region that are smaller than SE. It tends to smooth outward bumps, break narrow sections, and eliminate the thin protrusion. However, the closing has same effect in the invert image.

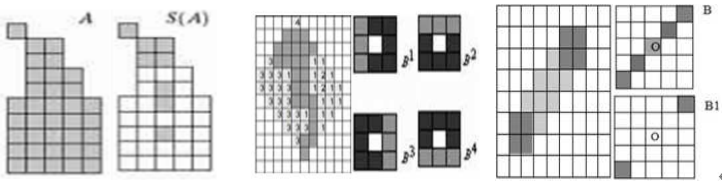
$$\gamma_B(f) = \delta_{\tilde{B}}\left[\varepsilon_B(f)\right] \quad (3) \qquad \phi_B(f) = \varepsilon_{\tilde{B}}\left[\delta_B(f)\right] \quad (4)$$

Skeletonization is one of the characteristics to description the geometrical shape and property of topological for images (shown in figure 2a). It has many applications in image compress, character recognition, and image regenerate.

The convex hull of a set is defined as the smallest convex set that contains A. And the convex (shown in figure 2b) is one in which the straight line joining any two points in the set consists of points that are also in the set.

2.2 proposed region-connected operation

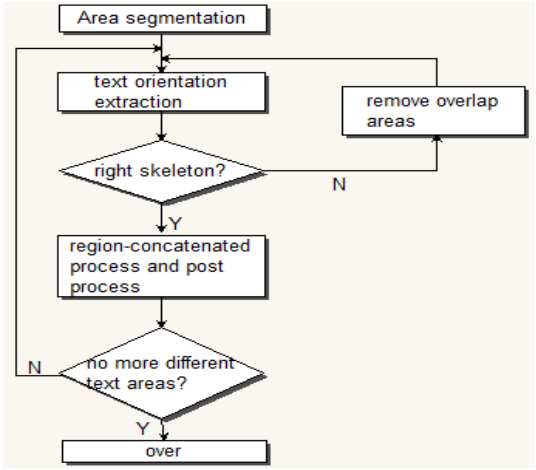
The region-connected operation can aggregate small connected domains to a big one. In this paper, it is required to concatenate small parts in a line. The proposed transform where B is a structure element, B1 is B's end points and f is figure:



F2a F2b F2c

$$\delta_B\left(\varepsilon_{B1}(f)\right) \cup f \quad (5)$$

This transform guarantees the end points of the connected line are included respectively in the two regions so that regions only grow in a single direction, which reduces the overlap between two neighbor lines (view in figure 2c).



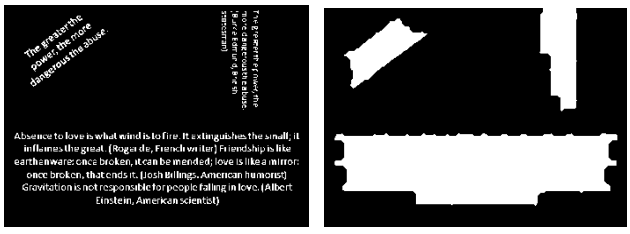
III. Proposed Methodology

The whole algorithm can be described as Fig.3:

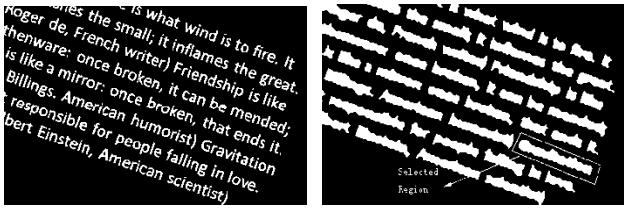
3.1 Area Segmentation Based on Layout

The proposed methodology focuses on pure text while there are many other methods for mixed document embedded with graphs or tables, to achieve text and non-text separation, like [5].

A pure text commonly has a particular layout and its characters needs to be separated to different areas based on layout, because in each area, the text orientation, font style and size are not similar, which would add the difficulties of later processing. As for figure 3.1a, the document image consists of three different parts whose orientation is distinct. The text image, therefore, needs area segmentation based on layout to separate the image into several different subgraphs. And aim at each subgraph of same orientation and size for later processing.



F3.1a F3.1b



F3.2a F3.2b

This paper uses closing operation with a big SE to fill the regions of same text orientation, which makes each part become

a whole connected area. Then label these parts and get different subgraphs. The result of figure 3.1a is shown as figure 3.1b in which the text image is divided to three parts.

3.2 Text Orientation Extraction

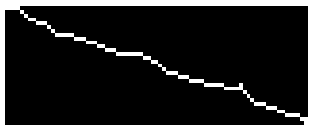
After area segmentation in 3.1, separated areas with the same text orientation are extracted, which could be handled respectively. In this and following sections, a new image is used for deep illustration and discuss.

Typically, line spacing is greater than the character spacing, which provides a feasible way to tell characters' writing direction. Use the closing operation towards figure 3.2a to fill the regions of small character spacing in a line, while the gap between two neighbor lines is still big enough for distinction (shown as figure 3.2b). Therefore, neighboring characters are clustered to rectangle-like connected regions. Obviously, these regions include the information of text orientation which can be obtained by extracting their skeletons.

Long skeleton is needed because it would help to concatenate regions in 3.4. There are two ways to find the longest skeleton：

① Extract all regions' skeleton and then find the longest skeleton

② Find the biggest region and extract its skeleton as the longest skeleton



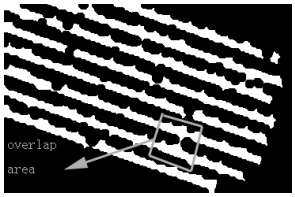
F3.2c

① may get the real longest skeleton but it causes more calculation consumptions than ② which only extract the skeleton of one connected region. In order to have a high speed performance, this paper adopts ② for the longest skeleton extraction.

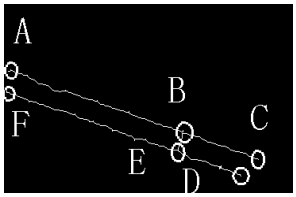
The biggest region is defined as a region which has the maximum connected pixels (shown as the region in a square frame in figure 3.2b). After finding the biggest region, use the method in 2.2 and get its skeleton. Such skeleton has some small branches, which needs skeleton pruning to roughly remove these branches and get the main skeleton (shown in F3.2c).

3.3 Judge and Remove Overlap Areas

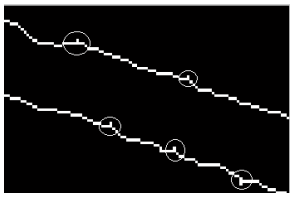
Problems may be caused by getting an incorrect skeleton when several skeletons would be considered as one skeleton by mistake due to the overlap of adjacent lines (in figure 3.3a). In the overlap situation, such false skeleton would be more likely to be found as the longest skeleton in 3.2 because its original connected region is usually bigger than others. Therefore, the process of judging and removing overlap areas is necessary to increase the algorithm's robustness.



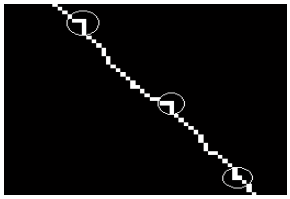
F3.3a



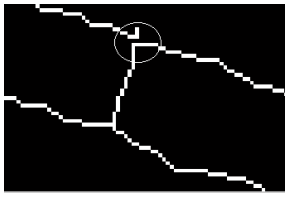
F3.3b



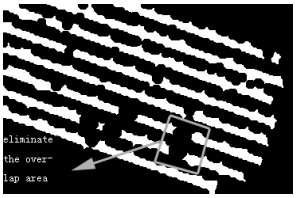
F3.3c



F3.3d



F3.3e



F3.3f

The incorrect skeletons have some common peculiarities (figure 3.3b):

①They contains branch points (B, E in Figure 3.3c)and more than two end points(A, C, D, F in Figure 3.3b).

②Their overlap-formed skeleton is usually smaller than the text line skeleton(BE is smaller than AC and FD in figure 3.3b).

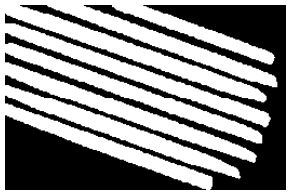
The expense of skeleton analysis utilizing ② is high because some small branch points (figure 3.3c,figure 3.3d) and breaking points (figure 3.3e) may disturb the normal analysis. All these defects will increase the scale of question whose analysis is inevitably at the cost of the spacial and time complexity of algorithm while these defects are tolerant sometimes (see figure 3.3d, such branch points will not bring bad influence to the result).

This paper focuses ① to solve or lessen the bad effect. If the number of endpoints is more than two or the number of branch points is not zero, it will regard the skeleton as wrong skeleton and do the process of removing overlap areas as below.

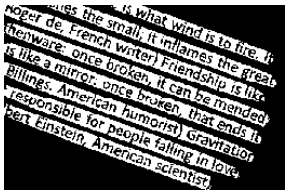
It gets the skeleton's branch points, dilates and inverses the points, and then intersects them with the original (figure 3.3a). It will eliminate the effect and get figure 3.3f. Regard figure 3.3f as new input to operations in 3.2 excluding closing operation till find a no branch point or two end points SE.

F3.4a

F3.4b

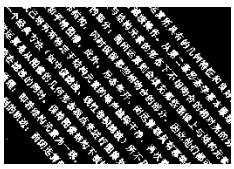


F3.4c



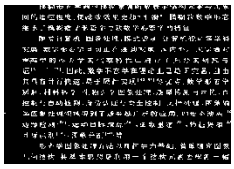
F3.4d

To avoid that skeleton pruning is too short to meet the subsequent actions' request, a maximum number of allowed loops is specified and the algorithm would then do the next process in 3.4 if it exceeds the number of cycles.



F4a

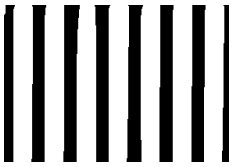
F4b



F4c

F4d

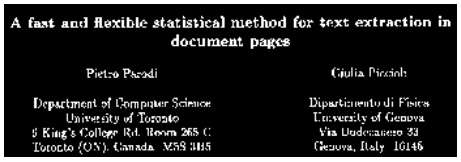
F4e



F4f

3.4 Region-Concatenated Process and Post Process

This step, at first, is making the skeleton as a SE and using a region-concatenated operation referred in part II towards figure 3.2b (the result is figure 3.4a). In order to eliminate the influence of picture's boundary, figure 3.4a is intersected with closing operation of figure 3.2a using a big SE whose result is figure 3.4b. Use a simple opening operation with the obtained SE to avoid new neighbor line overlap, and then generate convex hull image (figure 3.4c). This step will get a line region which can be analyzed and extracted to input into the OCR system (figure 3.4d). From figure 3.4d, the obtained domain nearly approach to the actual area of text.



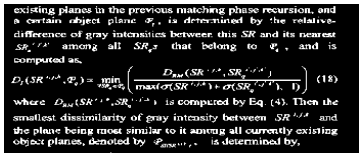
F4g

F4h

IV. Some other Experimental Results and Discuss

This section presents some results of the proposed text extraction algorithm on document images of various situations. Figure 4a, 4c and 4e are the inputs with the incline of 45^o ,0^o and 90^o . And figure 4b, 4d and 4f are the algorithm's output, which shows the suitable to a different language (Chinese) in different directions and sizes. Notably, the result of Chinese text is more parallel and regular than Latin's due to its character's peculiarity of equal height which reduces the overlap possibility and makes the line equal width without sharp fluctuation like Latin's.

Figure 4g whose font of characters is not same in different lines does not use area segmentation and employs the remaining steps deliberately. Its result (figure 4h) shows the algorithm's robust to more complex environment.



F4i

F4j

However, in some other situations especially when character spacing is less than line spacing (see in F4i with the irritation of expression), the discovered SE in 3.3 is strange or small because the overlap of neighbor lines is in an unquenchable state that causes more branch points to be found and strike themselves out in the original which means smaller connected regions and shorter skeleton found in the end. The result of figure 4i before the convex hull operation (see in figure 4j) shows the line's rupture area and holes due to the unfit skeleton.

V.Conclusions

This paper presents a new and effective method building on morphological image process which copes well with some usual occasions and is robust to the overlap between two neighbor lines. Text extraction in such a way can match the background detection and illumination normalization which also adopt the morphological strategy. It is also able to work on low- resolution.

The algorithm is concise and independent of text orientation, font style and size, language and layout, which adds its flexibility to most of specific situations with high calculation performance and compatibility with some morphological image preprocess operations; nevertheless, some improvements need to do for more sophisticated situation like grey or colorful images, font size excessively changed in a line, table-contained or formula-contained document and a text of slight contrast of line spacing and character spacing.

Keyworks：HF communication, Majority combining, Multi-point receiving

Abstract: HF communication is a very important tactical communication method, which can achieve thousand-miles away communication through the ionosphere reflections without any infrastructure support. But HF communication quality is not stable for the ionosphere disturbance, multipath fading and propagation loss. In this paper, we propose a new long-range communication scheme based on majority combing. In the scheme, we use multi-point receiving and multi-copying transmission, which can significantly improve the communication success rate by utilizing the land-sites' space diversity and the multi-packet's time diversity.

0 Introduction

Satellite communications capacity and stable communication quality, has been favored by the military, as a major means of remote communication security. But relatively fixed, satellite orbit is in danger of being shot down in the war, In February 2008, the U.S. west coast emission standard in Hawaii - missile, shoot down a spy satellite USA193 successfully, this is a wake-up call to foreign military, it also makes the short-wave communication to high priority.

Short-wave communication is also called high-frequency (HF) communication, using the frequency range for 3 ~ 30 MHZ, the main advantage of sky-wave reflected by the ionosphere, relay stations can be achieved without creating thousands of kilometers of long-distance communication. Short wave is the only from the network hub and active relay institutional constraints of the remote communication means, and also has the advantages of circuit set up quickly, anti-destroying ability is strong.

But compared to shortwave communications satellite communications, there are still large gaps in communication reliability. Short-wave telecommunication relies on sky wave transmission mode. After sky wave transmitting need short wave signal by the antenna into the ionosphere, the ionospheric reflected back to the ground, and by ground reflected back into the ionosphere, reflect many times, and spread distance (hundreds or thousands of kilometers), and is not affected by the ground obstacles blocking. But the ionosphere poor stability, coupled with path attenuation, time delay, multi-path effects and other factors that could cause weakening and distortion of the signal, thus affecting the results shortwave communication. How to improve the reliability of HF communications, has been a hot issue in the countries industry, academia research.

1 Shortwave military communication research status

U.S. shortwave communication research is a world leader, its third-generation HF communication network has been put into use, based on the U.S. military standard MIL-STD-188-141B foundation for shortwave sky wave transmission characteristics, focusing on the design of adaptive frequency selection techniques, combined with channel sounding and evaluation, make both sides of communication can choose the optimal frequency of communication; And designed the automatic link establishment mechanism, make its reliability, ease of use and channel utilization efficiency is greatly improved.

Draw lessons from the third generation of shortwave communication network in China, similar adaptive frequency selection system is designed and put into use, makes the performance of the communication must be improved, but there are still problems in the long-distance communication is unstable sea shore communications, especially in the fleet is far way to the gulf of Aden and I first island chain ocean-going fleet over the Okinawa sailing on the way, it is the second island chain area were once an intermittent communication problem.

2 Long-range communication scheme based on majority combing

Coastal areas with a large number of sites, used for the investigation and communication security. Through the shore-based cable network connection between these sites, and data interaction between command posts, shown in Figure 1. Based on existing equipment and the existing communications site, design engineering means between the improvement of shore sea short-wave communication performance is a problem to be solved. The author's idea is to coastal stations networked communications, the use of space diversity advantage of each site, improving the success rate of ship traffic.

Command post can choose a site to establish communication with ship, if the land-based sites work at the same frequency, the data sent by ship multiple sites may receive. Each site location, radio, the antenna performance is not the same performance, the objective has geographical diversity advantage, short-wave communication error for sudden fault, if the site data fusion, is bound to improve the success rate of communication. Based on this consideration, combined with large numbers of ruling principles, designed for sea-multi-point delivery mechanism to receive and redundancy mechanisms.

2.1 Shore-to-ship multi-receiver mechanism

Currently the data packet contains a CRC, the receiver can determine the received message is wrong. When receiving ship, site A, B, C will play time stamp on the data received through the shore-based wired network transmission to the command post, the time synchronization between three sites can be through the network synchronization protocol.

Command post to receive three site data, first of all, according to the time stamp, judge for the same data, and then respectively for CRC check three site data. If there is any site message correctly, CRC check it send the data to the upper applications use; If all site message CRC errors, then the data on the three sites by large numbers of bits judgment. For example, one data packet, judging site A and C is 1, site B judgment is 0, argues that the bit is 1. To participate in more receiving site is not limited to three, shore to the ship's multipoint receives the essence is the use of the site space diversity advantage.

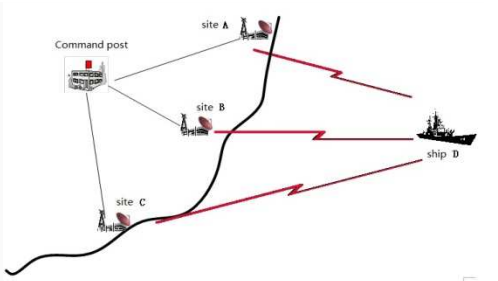

Figure.1 Shore sea communication diagram

2.2 shore to ship to send redundant mechanism

When sending data, no shore-to-ship between the ship station wired network connection or just a ship,not multi-point reception. However, the packet shore station can send multiple times in a row, after the ship station receives shore station data from the packet header sync start time set time window, the convention multiple packet data within the time window as the same packet data.

Assume that choose station B to ship station D communication command post, station B to ship station D continue to send the same package data, after you receive the ship station D, similar to receive more processing, will be 3 separate package data, respectively for CRC check, if any one pack of check is passed to the upper right agreement. If all the data packets are CRC errors, then the data bit by bit to three bags of Tarsus judgment, if two packets of data with a 1, then the judge is a bit, but after the data is transmitted to the upper layer protocol fusion . Redundancy is not limited to the number of sent three times, shore-to-ship redundant essence is the use of the time to send the packet diversity advantage.

3 Performance Analysis

in ship to receive the multipoint receives, using redundancy in the ship to send to send, with the need of ruling of large number, site and redundancy to send all can only take an odd number.

3.1 Multi-point performance

Assume that sends a packet length of L, m a shore-based sites at the same time receive ship station data, Ai represents the i-th station correctly receives the event data packets, the CRC check, B for each site receives data were wrong, bit by bit after the decision after receiving large numbers correct event, PM behalf of the packet error rate, which means that each site receives falsities, and by large numbers of probability judgment has still not correct [2].

There are: $P_M = 1 - \Pr\{A_1 \bigcup A_2 \bigcup \ldots \bigcup A_m \bigcup B\}$ (1)

Set any site k for Pk transmission error rate, the success rate of transmission of corresponding qk = 1 - Pk, right after receive more judgment of large number of conditions: the message in any one, if m, a site to receive the right site for more than half hour. Additional decision conditions of large number of formula 1, after receiving more still receive the error probability as shown in the Equation 2:

$$P_M = \sum_{k=0}^{m^*} (-1)^k \sum_{1\le i1<\ldots ik\le m} \cdots \sum (q_{i1}\ldots q_{ik})^L \left[1 - \left(\frac{q_1\ldots q_m}{q_{i1}\ldots q_{ik}} \sum_{s=0}^{m^*} \sum_{1\le j1<\ldots<js\le m} \cdots \sum \frac{P_{j1}\ldots P_{js}}{q_{j1}\ldots q_{js}}\right)^L\right] \quad (2)$$

Among them $m^* = \lfloor m/2 \rfloor$, for m half rounded down.

3.2 Redundancy send performance

If the ship station received m package data, a packet of data CRC checking them correctly, that the package is correct. If all packages of CRC errors, the ruling principle of large Numbers for error correction. Set all packages of CRC error probability for Psc, the probability of successful correction after a judgment of large number of Qmc | sc, the latter as a conditional probability. Finally after judgment of large number, packet transmission error rate expressed in Psc + Mc [3].

The three relations as shown in the Equation 3:

$$P_{SC+MC} = P_{SC} - Q_{MC/SC} \quad (3)$$

Is the conditions of success in judgment of large number of packet length L in any one, at least m, more than half a pack the bit transmission right, thus can get after the judgment of large number of packet error rate as shown in the Equation 4:

$$P_{SC+MC} = \sum_{k=0}^{\lfloor m/2 \rfloor} (-1)^k \binom{m}{k} \cdot q^{kL} \cdot \left\{1 - \left[\sum_{j=0}^{\lfloor m/2 \rfloor} \binom{m-k}{j} \cdot p^j \cdot q^{(m-k)-j}\right]^L\right\} \quad (4)$$

The p is the bit error rate, L is the packet length, m is the number of repetitions.

4 The simulation results

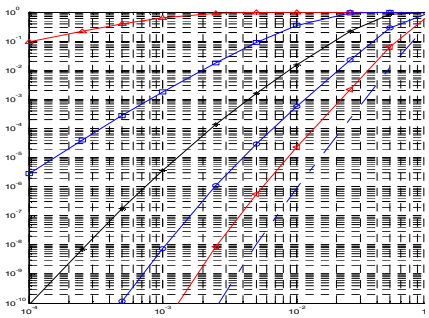
4.1 Multi-point reception

Matlab simulation on receiving multicast, fixed packet length L for 1000bit, m respectively 1, 3, 5, 7, 9, 11, the horizontal axis shows the bit error rate, longitudinal axis packet error rate, the simulation results are shown in figure 2:

With the increase of shore-based sites, performance gradually improved.When m = 5, the bit error rate is 0.001, the packet error rate is less than 10-5, its single point receiving the packet error rate nearly 100%, visible performance has improved.

4.2 Send redundancy

Fixed packet length L for 1000 bit, m respectively 1, 3, 5, 7, 9, 11, the horizontal axis shows the bit error rate, longitudinal axis packet error rate, the simulation results as shown in figure 3:



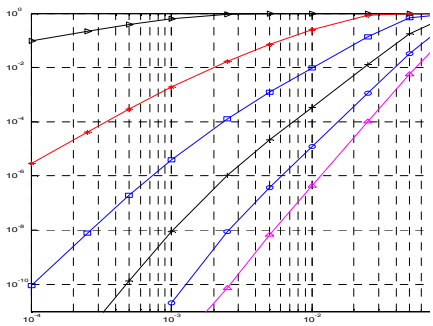


Figure 2 Fixed packet length multi-point emulation Figure 3 Fixed packet length redundancy send Simulation

With the increase of packet repetitions, the system performance improved significantly. When m = 5, the bit error rate is 0.001, the packet error rate is less than 10 to 5, the single point of single message when sending the packet error rate close to 100%, visible performance has improved.

From the simulation result shows that with the increase of the terminal points and the number of repeat sending message, communication performance improved significantly. But combined with the practical engineering application, take 5 site or send 5 repetitions can obtain satisfactory effect.

5 Conclusion

In this paper,Based on coastal both the shortwave communication site, the network use, take advantage of its geographical diversity, design the multipoint receiving mechanism, and the redundancy of ship station design send mechanism, by giving full play to the advantages of time diversity.

Theoretical analysis and simulation results show that, during the shore-ship communication packet length is set to 1000bit, the bit error rate of 0.001, the receiver-ship multi-receiver using five sites, to ship a single packet to send the case five times, the success rate of the ship receiving and sending better than 99.9999% success rate after large numbers verdict. The traditional single-point transceiver, the success rate for sending and receiving ship station success rate tends to zero. Visible, the scheme for communication between shore sea success rate improve significantly.

Keywords: complex image method, periodic Green's function, perfectly conducting periodic surfaces, electromagnetic scattering.

Abstract. In this paper, an improved complex image method to derive closed form periodic Green's function for problem of scattering from perfectly conducting periodic surfaces is considered. The complex image technique represents a close-form periodic Green's function consisting of a finite series of real sources and two finite series of complex sources with complex locations and amplitudes. Then the integral equation with the complex images periodic Green's function in the kernel is solved by the method of moments. Results and computational times obtained by this improved complex image method and the previous one are compared with those obtained by the spectral Kummer-Poisson's method. Results show that the improved complex image method is more accurately than the previous one.

Introduction

The problem of evaluating the scattering of waves by periodic surfaces is one of fundamental importance in science and engineering [1-3]. Integral equation approaches in combination with the method of moments are among the most frequently used in the solution of scattering problems related to periodic surface due to their flexibility in modeling different geometries [4, 5]. The integral equation of electromagnetic scattering problems from periodic surfaces requires the efficient and accurate computation of periodic Green's functions [4]. The application of the Floquet-Bloch theorem reduces the computational domain of infinite periodic surfaces to a single unit period, but leads to results that involve the numerical evaluation of very slowly converging series [4]. This may cause serious difficulties in terms of the computational time, in order to speed up the evaluation of these series lots of acceleration techniques have been proposed in the literature [6-8]. Although these methods can be successfully applied to the periodic Green's functions, they are all derived no closed-form representation of the periodic Green's function. Since the periodic Green's functions are used in the kernel of the integral equations, it is necessary to derive closed-form periodic Green's functions.

In [9], a discrete complex image method was introduced to represent a closed-form periodic Green's function. However we have observed that the previous method fails to get accurate results when $2\pi h / p$ is much bigger than 0.448[10]. Here in this study an improved complex image method which is useful in deriving closed-form expressions to give more accurate results than previous results for the periodic Green's function, is considered.

Formulation of the Problem

The considered structure is represented in Fig.1. Consider a plane wave incident upon a periodic surface with height function z=f(x), such that f(x+p)=f(x). The period of the rough surface is p in the x-direction. The incident direction is in the x-z plane. The electric field of the incident wave is given by

$$\psi_{inc}(r) = \hat{y}e^{-jk_x x + jk_z z} = \hat{y}e^{-jk\sin(\theta_i)x + jk\cos(\theta_i)z} \tag{1}$$

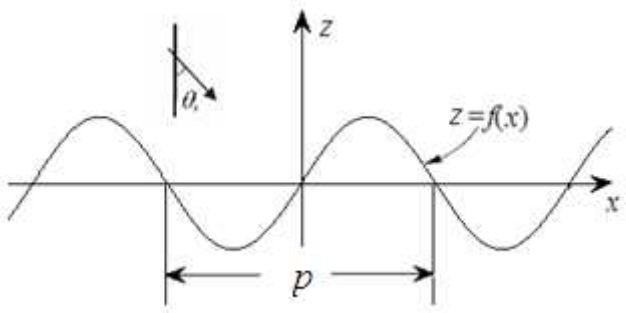

Fig. 1. The geometry of the problem

Applying the PEC boundary condition on the surface, the problem can be reduced to solution of the following integral equation [4]

$$\psi_{inc}(\overline{r}) - \int_{-\infty}^{\infty} G(\overline{r},\overline{r}')\hat{n}'\cdot\nabla'\psi(\overline{r}')d\sigma' = 0 \tag{2}$$

All the field points $\overline{r}$ are on the surface. The surface integral in (2) is over infinite surface. By applying the Floquet-Bloch theorem to limit the analysis to a representative unit period, the surface integral can be condensed into a single period [4]

$$\psi_{inc}(\overline{r}) = \int_{-p/2}^{p/2} G_p(\overline{r},\overline{r}')u(x')dx' \tag{3}$$

Where

$$u(x')dx' = (d\sigma'\hat{n}'\cdot\nabla'\psi(\overline{r}'))_{z'=f(x')} \tag{4}$$

$$\begin{aligned} G_p(x,z;x',z') &= \sum_{m=-\infty}^{\infty} G(x,z;x'+mp,z')e^{-jmpk_x} = \sum_{m=-M}^{M} G(x,z;x'+mp,z')e^{-jmpk_x} \\ &+ \sum_{m=-\infty}^{-M-1} G(x,z;x'+mp,z')e^{-jmpk_x} + \sum_{m=M+1}^{\infty} G(x,z;x'+mp,z')e^{-jmpk_x} \end{aligned} \tag{5}$$

where M is a positive integer, and the first term in the right side of (5) is the source point's effect in the middle 2M+1 periods, which will be preserved in the final representation. While the sources point's effect in the other two remaining infinite period can be represented by two finite series of complex images respectively using the complex image method. In order to derive the complex images representation of the last two infinite terms of (5) one can use the following identity

$$\begin{aligned} G(x,z;x'+mp,z') &= \frac{H_0^{(2)}(k\sqrt{(x-x'-mp)^2+(z-z')^2})}{4j} \\ &= \frac{1}{2\pi}\int_{-\infty}^{\infty}\frac{e^{-j\beta_x|x-x'-mp|}}{j2\beta_x}e^{-jk_z(z-z')}dk_z \end{aligned} \tag{6}$$

Where $\beta_x = \sqrt{k^2 - k_z^2}$. By substituting (6) in (5) and changing the order of summation and integration operators, the last two infinite series can be easily written as

$$\begin{aligned} \sum_{m=-\infty}^{-M-1} G(x,z;x'+mp,z')e^{-jmpk_x} &= \frac{1}{2\pi}\int_{-\infty}^{\infty}\sum_{m=-\infty}^{-M-1}\frac{e^{-j\beta_x|x-x'-mp|}}{j2\beta_x}e^{-jmpk_x}e^{-jk_z(z-z')}dk_z \\ &= \frac{1}{2\pi}\int_{-\infty}^{\infty}\frac{1}{j2\beta_x}e^{jMk_x p}e^{-j\beta_x(x-x'+Mp)}\frac{e^{j(k_x-\beta_x)p}}{1-e^{j(k_x-\beta_x)p}}e^{-jk_z(z-z')}dk_z \end{aligned} \tag{7}$$

$$\begin{aligned} \sum_{m=M+1}^{\infty} G(x,z;x'+mp,z')e^{-jmpk_x} &= \frac{1}{2\pi}\int_{-\infty}^{\infty}\sum_{m=M+1}^{\infty}\frac{e^{-j\beta_x|x-x'-mp|}}{j2\beta_x}e^{-jmpk_x}e^{-jk_z(z-z')}dk_z \\ &= \frac{1}{2\pi}\int_{-\infty}^{\infty}\frac{1}{j2\beta_x}e^{-jMk_x p}e^{j\beta_x(x-x'-Mp)}\frac{e^{-j(k_x+\beta_x)p}}{1-e^{-j(k_x+\beta_x)p}}e^{-jk_z(z-z')}dk_z \end{aligned} \tag{8}$$

The quotients in (7) and (8) can be approximated by a finite series of exponential as

$$\frac{e^{j(k_x-\beta_x)p}}{1-e^{j(k_x-\beta_x)p}}=\sum_{m=1}^{M1}a_m e^{b_m\beta_x} \tag{9}$$

And

$$\frac{e^{-j(k_x+\beta_x)p}}{1-e^{-j(k_x+\beta_x)p}}=\sum_{m=1}^{M2}c_m e^{d_m\beta_x} \tag{10}$$

Because the Generalized pencil-of-function method (GPOF) [11,12] has turned out to be quite robust and less noise sensitive when compared to the original and least-square Prony's methods [11-14], we using GPOF approximates the quotients. The parameters M1 and M2 can be determined by the GPOF method [14].

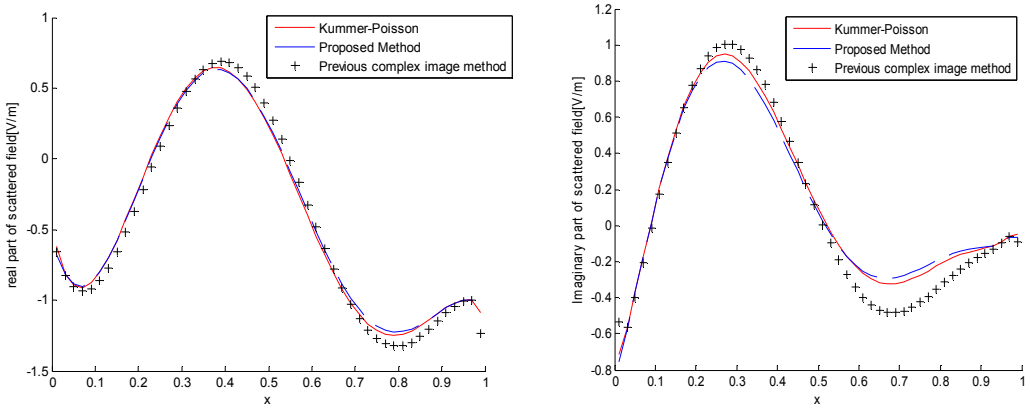
The spatial Green's functions can be obtained through the inverse Hankel transform, which is generally referred to as the Sommerfeld integrals. Substituting the above equation (9) in (7) and (10) in (8) respectively then using identity (6) the following results will be obtained:

$$\begin{aligned}G_p(x,z;x',z')&=\frac{1}{4j}\sum_{m=-M}^{M}e^{-jk_x mp}H_0^{(2)}(k\sqrt{(x-x'-mp)^2+(z-z')^2})\\&+\sum_{m=1}^{M1}a_m\frac{e^{jMk_x p}}{4j}H_0^{(2)}(k\sqrt{(|x-x'+Mp|+jb_m)^2+(z-z')^2})\\&+\sum_{m=1}^{M2}c_m\frac{e^{-jMk_x p}}{4j}H_0^{(2)}(k\sqrt{(|x-x'-Mp|+jd_m)^2+(z-z')^2})\end{aligned} \tag{11}$$

This completes the derivation of complex images representation of the periodic Green's function of (5). It can be seen that the first summation of terms in (11) corresponds to the sources points in the middle 2M+1 periods that have the most significant effects on the field points located in a unit period. The presence of these terms in the final result guarantees satisfactory results for the near fields especially in the vicinity of the unit period surface. While the other two summation of terms in (11) known as complex images correspond to the sources points in the two remaining infinite periods respectively have the same forms as real sources except their complex locations in space and complex values. They are more important when the field point is located far away from the surface within a unit period. The complex images representation in the previous method is a particular case when M is set to 1 of the one in this paper. When $2\pi h/p$ is much bigger than 0.448[10], the representation in the previous method wouldn't get accuracy results for the near fields because the real sources which guarantees satisfactory results for the near fields is not much enough. So big M is needed to get more accuracy results and the improved complex image method can deal with deep grating.

Numerical Results

In this section, we study the accuracy of the technique given in the previous section by considering some illustrative examples. The obtained results are compared with the previous complex image method and the Kummer-Poisson. In all cases, object is assumed to be located in free space illuminated by plane wave with frequency 400 MHz. First example is a periodic surface having sinusoidal variation of the form $f(x)=0.2\cos(\frac{2\pi}{L}x)$, incident angle is chosen as 60°, L=1 and scattered field are calculated on plane Zf =0.2 above the rough surface. Results are compared in Fig. 2. In Fig. 3, the real and imaginary parts of the scattered field calculated on plane Zf =0.8 for incident angle $\theta_i=45^\circ$ and roughness function of surfaces within one period are chosen as $f(x)=0.8\cos(\frac{2\pi}{L}x)$ with L=3.



(a) (b)

Fig. 3. Scattered field above rough surface within one period(a)real part,(b)imaginary part(λ=0.25p, h=4p/15)

Conclusions

In this paper, an improved complex image technique has been presented for the calculation of periodic Green's functions for problem of scattering from perfectly conducting periodic surfaces. The complex image technique represents a close-form periodic Green's function consisting of a finite series of real sources in the middle 2M+1 periods and two finite series of complex images correspond to the sources points in the two remaining infinite periods respectively. The proposed method can give more accurate evaluation of the periodic Green's function than the previous method for the deep grating scattering problem. Numerical results show that the improved complex image technique has a better agreement with the spectral Kummer-Poisson's method than the previous one.

Keywords: Full-wave band CCD system; Image extraction;Image processing

Abstract. The full-wave band CCD system is widely used for military,civil or photography of criminal image and extraction analysis,its wavelength is range between 200 nm and 1200 nm,including ultraviolet,visible light and infrared.Through translating blanck visibleimage into optical image,and realizing collecting of weak signal under low illumination case and collecting and processing of high quality image,it makes Full-wavelength CCD system the powerful features such as the topography and landform scaning,traces exploration,file inspection,holographic photography and image processing.The whole band CCD system structure,characteristic and the application of the image interpretation technology were briefly introduced in this paper,and experiment band CCD selected was validated.

Introduction

The Full-wave band CCD camera is developed at first by U.S.A.,apply to study the technological field in spaceflight,army industry science at first,this equipment adopts and lengthens time for exposure and method to reduce noise mainly,in a situation that the intensity of illumination is low or the mark material evidence is very faint,can get the comparatively clear picture,at the same time,can comparatively lower the interference of the background of the object effectively too,it is one of the most advanced taking pictures tools at present.The Full-wave band CCD system shows and professional pattern process equipment in real time purple outside of one set,visible light,infrared picture high-resolution.It can visible light picture turn visible light picture into in real time,can realize faint collection and high-quality collection and processing of picture of signal under the low intensity of illumination situation, incorporate the verification of traces,file are examined,figure taking pictures and pattern process into an organic whole.

Images drawing and analysing

Introduction to the experiment platform. The size or picture of laser scanning based on CCD system shows measures the experimental provision.Three-dimensional laser scanning that device adopt this,overcome traditional vision machine succeed the two-dimentional picture three-dimensional scenery projection,cause and construct the three-dimensional scenery only defect again.Survey and draw and gather clicking more under this system,the depth of field of the picture is long,make the treated data true and reliable.The structure of the experimental provision and size of laser scanning of operation principle measure the device system and adopt the single track mere law of structure,this system including semiconductor laser instrument,CCD camera,picture gather card,computer , measuring platform,measuring and pattern process software etc.

The systematic flow chart is as Fig.1 shows.The system regards semiconductor laser instrument as the light source,its light beam is become on the fan-shaped level of the vertical direction only shone and examined the thing by the optical system,being examined and forming the stripe on the thing.Sloping and observing this stripe to get a stripe picture with CCD camera,the data information of the income is gathered the card by the picture and sent into the computer and dealt with from the

software of measuring, according to geometrical optics and this stripe deformation along z high change,axle of direction conversion of pattern triangular law.And is examined the thing and moved according to certain law in certain direction,so can receive the depth picture information on the object surface.

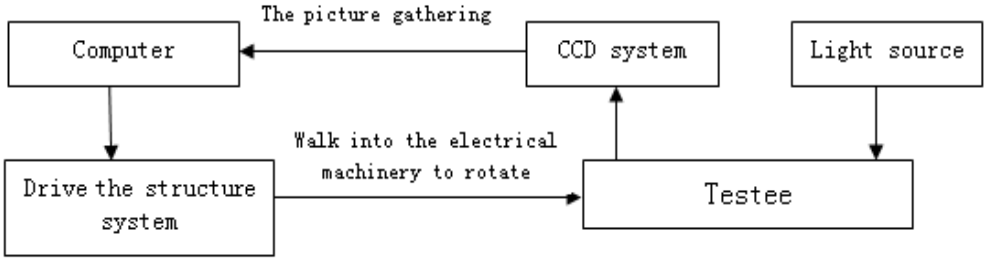

Fig 1. Systematic job flow chart

Measure the principle. In order to state the systematic measurement principle,introduce system of coordinates and position relation used in the system at first,as Fig.2 shows.

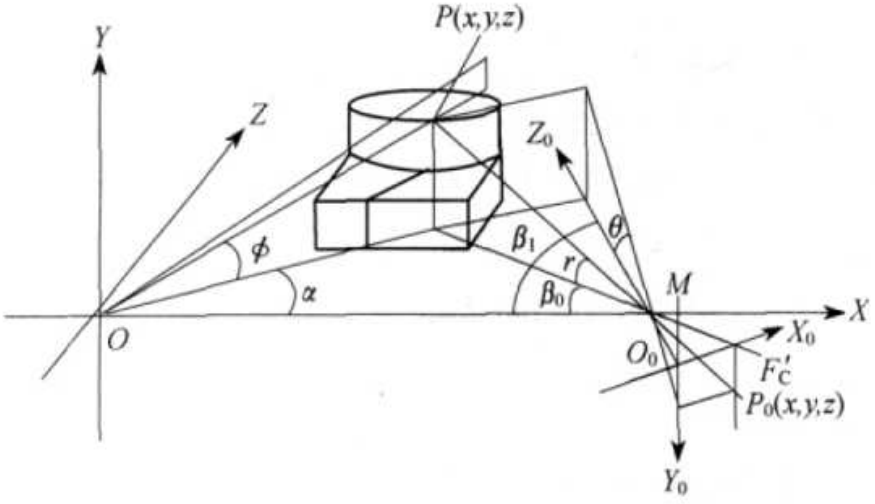

Fig 2.The systematic system of coordinates and position relation

The relation between the systematic system of coordinates of Fig.2 and these 3 kinds of coordinates of position relation is:System is it run to pass, receive goal thing and indicate picture yuans of screen coordinate that order at first,then change into a level coordinate of the image,could vary various kinds of with the square space coordinates of the thing finally,three-dimensional coordinate that thus it is superficial to get objects.

$$\tan(\beta_1-\beta_0)=\frac{O_0P_0'}{OM}=\frac{O_0P_0'}{f} \tag{1}$$

$$f=Nx\cot\theta_1\ ,Z=\frac{B}{\cot\beta_0} \tag{2}$$

$$Z=B\left(\frac{f-x\cot\beta_1}{f_x+f\cot\beta_1}\right)=B\frac{1-n\left(\cot\beta_1\tan\theta_1\right)/N}{\cot\beta_1+n\left(\tan\theta_1/N\right)} \tag{3}$$

Gather the card to a definite CCD camera and a definite picture,picture yuans of screen system of coordinates and image conversion,level of system of coordinates relation regular,as yuans of system of coordinates changed into a level coordinate of the image directly,but can read directly at the computer.The relation is between every parameter that can be won by the geometry principle of the camera.

$$f=Myx\cot\theta_2\ ,\tan\theta=\frac{my}{f}=\frac{my}{My\cot\theta_2}=m\tan\theta_2/M \tag{4}$$

$$X = Z\cot\alpha = 0, Y = \tan\theta\cos\left(\beta_1 - \beta_0\right)Z / M\left(\sin\beta_0\right) \quad (5)$$

$$Y = \frac{Z\left(\tan\theta_2\right)/M \cdot m}{\sin\beta_1 - \cos\beta_1\left(\tan\theta_1\right)/N \cdot n} \quad (6)$$

The experiment verifying. Measure the material object and adopt diameter 5 mm,the cylindrical part of high 80 mm,walking into amount 2 mm,the system adopts the standard volume one standardly,a distance clicked with consult coordinates of measuring amount is as the standard depth,measure a height and is regarded as the standard height.Can know from the result of measuring,the data measured move towards the form with the clause to accord with,can guarantee the precision.The three-dimensional laser scanning that the size of laser scanning based on CCD measures the experimental provision and adopts is different from simple survey and drawing technology,it can describe the intact attribute of the goal structure,is suitable for the original appearance of reducing the more goal.

Application of the Full-wave band CCD system in image technology

Inspection for the file or the fabrics. In writing the ink to examine,the ink of some brands displays the fluorescence under the circumstances that much wave band light sources shine,and have many kinds of colors changes.For example,the pen of different colors,ink of ball pen and signature pen are under the circumstances that indoor light and much wave band light sources shine separately,the fluorescence of some ink appears orange,some are partial and yellow.In addition,write the layer after the analytic approach of thin layer is divided layer of ink on the file and analyse and pursue,under many wave band light sources,some compositions will produce the strong fluorescence,and the difference exists in the position that the fluorescence will be brought,so can distinguish the ink of different brands conveniently.Equally,the fabrics fibre adhered to the clothes,some can produce the fluorescence too in specific wave band light.Utilize many wave band light sources to collect these fibres easily,and the dyestuffs in these fibres can adopt the analytic approach of thin layer to launch,and then shoot with the Full-wave band CCD system,thus differentiate the difference.

Inspection for the fingerprint,footprint or body fluid. In the course of using the Full-wave band CCD system and carrying on fingerprint to examine.The potential fingerprint on the plastic products after the cyanogen acrylic acid fat is dealt with,and then float and dye with Rodin bright 6G dyestuffs,observe under the indoor light and the Full-wave band CCD system separately,the latter fluorescence is strong,fingerprint appears clearly.Three ketone derivatives of indene developed in recent years,cooperate with the chlorine treated fingerprint of zinc solution,it will produce a lot of fluorescence results too that the Full-wave band CCD system is observed,it is with high efficiency that the fluorescence gives out light, traditional three ketone laws of indene that superior to.Equally,there is strong fluorescence too under the Full-wave band CCD system to examine chemical medicines DFO used in technology in laser fingerprint.In a word,use the Full-wave band CCD system to dispel the mark background to interfere effectively,strengthen image contrast.CCD system can be used for appearing to the footprint in addition.To the optics method,can all shoot appearing with the Full-wave band CCD system.As to ordinary camera, the Full-wave band CCD system is in the method of appearing of optics,it is quicker that it manifests the speed,and it is even more ideal to manifest the result,especially it is more obvious to reflect its advantage while taking pictures purple outside.

Inspection for the ammunition leftovers. Launch ammunition after remain mark have barium salt,appear orange fluorescence particle form distribute until the whole system,CCD of wave band, observe,but as differentiating the basis of launching the entry,the experiment indicates,adopt the Full-wave band CCD system to shoot apter existence of observing the barium salt particle in the room on the black carrier.

For fighting the inspection of place shape or ground form. The modern battle field is by enormous C4I system that light,electronics and information network disposing on the

multidimensional space make up, among them the information subsystem is one of the main backbones.Through adopting various kinds of and detecting and examining the characteristic information that technology and means obtain enemy's goal in one's own side's army,rely on the medium to convey to the acception station directly or in the form of sound,light,electric wave,processing,showing writing down,interpretation, the course of analysing etc.is turned into the available information.The modern battle field situation is fast changing,the commander will not establish in an unassailable position unless grasp enemy and our accurate situations of both sides in time.So the intelligence work must be continuous,real-time,information processing automation.No matter take any means,it is an essential procedure to detect and examine. According to the characteristics of the object and electromagnetic wave,scientific and technical personnel develop the varied reconnaissance means,for example:The visible light reconnoiters the technology and equipment,the shimmer reconnoiters the technology and equipment,reconnoiter the technology and equipment infraredly,reconnoiter the equipment and reconnoiter the technology and equipment,the sensor reconnoiters the technology and equipment,the satellite reconnoiters etc.

Discussing

With the development of science and technology,the digitized picture of direct output of the Full-wave band CCD system,can also be real-time check-up is revised,the digitized process of making the whole information reconnoiter is accelerated greatly.The appearance of this system,the network enabling interpretation personnel and pattern process personnel to totally realize the digitized picture is real-time and mutual.Take a picture while manifesting various kinds of topographical ground form or the mark material evidence with the Full-wave band CCD system,besides mixing the light and focusing,other work is finished in the computer,and the picture got is all right appear " real-timly " on the monitor.Especially to take pictures to purple outside and infraredly,all right to be " real-time " sees the picture ,so can adjust and match all angle according to the power of contrast,avoid " striking blindly ". But the one that need to pay attention to at the same time is,as the conditions,such as light source,illumination,etc.are limited and influenced,what a deep question that thinks that the effective one goes to make an uproar to become worth.

Keywords: channel estimation, OFDM, CIR (Channel Impulse Response), gate processing

Abstract. An improved discrete Fourier transform DFT-based channel estimation for OFDM systems is proposed. Conventional DFT-based channel estimator improved its performance by suppressing noise, but it does not completely suppress noise. In order to overcome the disadvantage, this paper proposed a gate method without requiring any channel statistical information. This method comprehensively considersthe effects of the power of the strongest path and the noises. Computer simulation demonstrates the performance of the proposed algorithms in terms of bit error rate.

Introduction

For coherent orthogonal frequency division multiplexing (OFDM) systems, a robust channel estimator is required critical to improve the performance of systems. By now, various OFDM channel estimation schemes have been proposed in the literature. In general, the least square estimator is the simplest channel estimation [1]. However, it is limited by the noise and inter-carrier interference.The minimum mean-square error MMSE [2] estimator is a well-known channel estimator. But the high computation complexity is a serious disadvantage. Zhao et al [3] introduced additional DFT processing to obtain the frequency response of LS estimated channel. Based on discriminant analysis, Fan [4,5] presented dynamic time-domain threshold for channel estimation.

By suppressing time domain noise, conventional DFT-based channel estimations improve the performance. However, in a multipath channel with non-sample-spaced time delays, this approach will cause power leakage and result in an error floor. After analyzing the property of Channel impulse response, an improved method based on gate processing is proposed. The gate value is got by the power of the strongest path and noises. The path whose power of CIR fails to reach the gate value is to be abandoned. So, the improved method can retain the CIRs and remove the noises at the same time, enhance the accuracy of estimation and the performance of system.

System description and channel model

OFDM System Model. We consider an OFDM system that consists of N sub-carriers. And each sub-carrier consists of data symbol $X[k]$, where k represents the sub-carrier index. The OFDM transmitter uses an inverse DFT of size N for modulation. Then the transmitted OFDM signals in discrete-timedomain can be expressed as:

$$x[n]=\frac{1}{N}\sum_{k=0}^{N-1}X[k]\exp(j2\pi\frac{nk}{N}),\qquad 0\le n\le N-1. \tag{1}$$

Where n is the time domain sample index of an OFDMsignals. In order to avoid ISI caused by multipath channel and consequent ICI [6], GI is appended to thebeginning of the N sample of IDFT. After passing through a time-varying multi-path fadingchannel and removing the GI, one receivedsignal $y[n]$ consists of channel distorted versionsof the transmitted OFDM symbols, which isrepresented by

$$y[n]=x[n]\otimes h[n]+w[n]\qquad 0\le n\le N-1. \tag{2}$$

Where $\otimes$ denotes cyclic convolution operation. $w[n]$ is iid additive whiteGaussian noise (AWGN) sample in time domain with zeromean and variance σ_{wt}^2. $h[n]$ is the discrete-time CIR.

$$\sigma_{wt}^2 = E[|w[n]|^2] \tag{3}$$

A tapped delay line channel model of wireless fading channel $h(t,\tau)$ can be expressed as:

$$h(t,\tau) = \sum_{l=0}^{L-1} \alpha_l(t)\delta(\tau - \tau_l) \tag{4}$$

Where, $\alpha_l(t)$ is the energy of l-th paths, and L is the total number of paths; τ_l is the l-th path delay. Assume T_s is the sampling interval, the CIR $h(t,\tau)$ is a time-limited pulse train, so the frequency response will span over the whole frequency domain. The OFDM signal is frequency limited. Hence, the receiver can only probe part of the frequency response. In this case, the CIR can be denoted as:

$$h(n) = \frac{1}{N}\sum_{l=0}^{L-1} \alpha_l \, \mathrm{e}^{-j\frac{\pi}{N}(n+(N-1)\tau_l)} \frac{\sin(\pi\tau_l)}{\sin(\pi(\tau_l - n)/N)} \tag{5}$$

For non-sample-spaced channel, τ_l isn't an integer. From Eq(5), the energy will leak to all taps $h(n)$.

DFT-based Channel Estimation

To perform the DFT-based channel estimation, the Least Square (LS) channel estimates on the pilots are first obtained. At the receiver, the received pilot signals are extracted from $Y[k]$. Then the channel frequency response in pilot sub-channels can be estimated by:

$$\hat{H}_{LS}[k] = Y[k]/X[k] = H[k] + W[k]/X[k] \qquad k \in K_P. \tag{6}$$

where K_P is the ensemble of all pilot indexes. The greatest advantage of LS algorithm is its simple structure and lowly complexity. The conventional DFT-based estimation reduces the noise power that exists outside of the CIR. An N-point IDFT is used to $\hat{H}_{LS}[k]$, to obtain an estimate of the CIR:

$$\hat{h}_{LS}[n] = IDFT\{\hat{H}_{LS}[k]\} = h[n] + \tilde{w}[n] \qquad 0 \le n \le N-1. \tag{7}$$

Where $\tilde{w}[n]$ is IDFT sample of noise. The CIR is typically limited to the length of CIR L which is less than the GI and much smaller the number of sub-carrier N. Because L is unknown, $L = N_{cp}$. By zero-padding for pure noise period, the conventional DFT-based estimator can be expressed as:

$$\hat{h}_{DFT}[n] = \begin{cases} h[n] + \tilde{w}[n], & 0 \le n \le N_{CP} - 1 \\ 0, & N_{CP} \le n \le N-1 \end{cases}. \tag{8}$$

N_{CP} is the length of CP. From (8), the DFT-based channel estimator is denoted as

$$\hat{H}_{DFT}[k] = DFT_N\{\hat{h}_{DFT}[n]\} \qquad 0 \le k \le N-1. \tag{9}$$

Proposed channel estimation

As mentioned before, the noise is eliminated based on the length of the guard interval. However, the energy of the corresponding path will leak to all the taps in the time domain when the channel path delay is usually non-sample-spaced. Then this method will not only eliminate the noise, but also lose the useful leaked channel impulse response. So the error floor is caused by loss of leakage power.

Even though the energy of non-sample-spaced path leaks to all the taps, but most of the energy is kept in the neighborhood of the original pulse locations. From Eq(5), we can see the energy concentrates at the ends of the sequences. To avoid the gate value setting too high or toolow, a newproposedmethod is in the following:

Step1: Compute the initial LS channel estimate HLS[k] from the Eq(6).

Step2: Take IDFT of the LS estimate, hLS[n] from the Eq(7).

Step3: As mentioned step1, the channel taps $\hat{h}_{LS}[n]$ can be divided into three groups: $0 \le n < N_{cp}$, $N_{cp} \le n < N - N_{cp}$, $N - N_{cp} \le n < N - 1$. In the region $N_{cp} \le n < N - N_{cp}$, the channel taps $\hat{h}_{LS}[n]$ can be handled as the taps of noise, $\hat{h}[n] = 0$. The noise power is estimated by:

$$\sigma_{wt}^2 = \frac{1}{N - 2N_{cp} - 1} \sum_{i=N_{cp}}^{N-N_{cp}-1} \left| h_{LS}[n] \right|^2 = \frac{1}{N - 2N_{cp} - 1} \sum_{i=N_{cp}}^{N-N_{cp}-1} \left| w[n] \right|^2 \tag{10}$$

Step4: In the region $0 \le n < N_{cp}$ and $N - N_{cp} \le n < N - 1$.We design the gate value λ based on the biggest tap value $h_{\max}$ and the power of noise. If $\left| \hat{h}_{LS}[n] \right| > \lambda$, $\hat{h}[n] = \hat{h}_{LS}[n]$ and $\hat{h}_{LS}[n] = 0$.

$$\lambda = (\varepsilon \left\| h_{\max} \right\|^2 + \gamma \sigma_{wt}^2) \big/ (h_{\max} + \sigma_{wt}) \tag{11}$$

The abovegate value avoids the case in which the gate value is setting too high or too low. when $\left\| h_{\max} \right\|^2 >> \sigma_{wt}^2$, ε value can be adjusted to maintain λ bigger to filter the majority of noises. When $\left\| h_{\max} \right\|^2 << \sigma_{wt}^2$, γ valuecan beadjusted to maintain λ smaller to keep usefulinformation as much as possible. The value ε and γ can be generated by Monte-Carlo simulation.

Step5: Finally, the channel estimation can be achieved by:

$$\hat{H}[k] = DFT_N \{ \hat{h}\ [n] \} \tag{12}$$

As mention above, channel estimation based on the gate value can eliminated the impact of the noise. The improved algorithm is gate processing method, and DFT-GP is its abbreviation.

Simulation results and analysis

In this section, we will investigate the performance of the proposed algorithm on non-sample-spaced multipath channels, and the bit-error-rate (BER) performance is examined. The simulations are concentrated on comparison between LS algorithm, conventional DFT algorithm and the proposed algorithm. For simulation, we have considered an IEEE 802.16e OFDMA system. Table 1 summarizes major system parameters. In our simulation, we test different algorithms under ITU-R M.1225 vehicular A channel model, which is applied assuming the maximum mobile speed of $v_{\max}$ =120 km/h. It is a typical non-sample-spaced multipath channels which have six paths. In addition, perfect synchronization is assumed, since it is hard to estimate the channel frequency response beyond guard band.

Table 1 Major system parameters

Parameters	Values
Carrier frequency	2GHz
Bandwidth	10MHz
Cyclicprefix	128
Sampling frequency	11.2 MHz
Sub-carrier spacing	10.94kHz
System period	102.86μs
Guard interval	11.43μs
Data modulation type	16QAM
Pilot sequence modulation	BPSK

In the simulation, gate factors ε and γ are $\varepsilon = 1.2$ and $\gamma = 0.2$ .Fig. 2 shows the BER performances ofthree different methods under non-sample-spaced multipath channels.As shown in Fig2, it is obvious that the performances of DFT-GP channel estimators are better than DFT-based channel estimator.At low signal-to-noise ratio (SNR), by suppressing time domain noise, the conventional DFT algorithm is better than the LS algorithm. At high SNR, the performance degradation is induced when low energy CIR samples containing useful channel information are discarded.There existsan error floor.

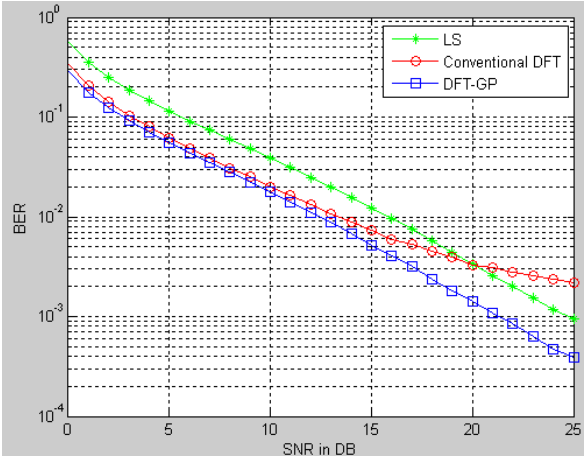

Figure1 BER performance with different channel estimation (CE)

Conclusion

In this paper, we proposed a gate processing channel estimation for OFDM system in non-sample-spaced multipah fading channel.Using two parameters threshold, this method can avoid the gate value setting too high or too low. The gate factors can be found by Monte-Carlo method. Simulation shows that the proposed method can achieve the better performance. In practice, the can be adjusted through feedback mechanism.

Keywords: Wavelength conversion, Quasi-phase matching, Ccascaded second harmonic generation and difference frequency generation, Bandwidth

Abstract. Bandwidth enhancement and response flattening of wavelength conversion based on single-pass and double-pass cascaded second harmonic generation and difference frequency generation in step-segmented quasi-phase matched (QPM) gratings are investigated. For the same waveguide length, high conversion efficiency, flat response and broad signal bandwidth can be obtained simultaneously by optimizing the poling period of the step-segmented QPM structure. The conversion bandwidths in a 3-cm-long five-step-segmented waveguide are 134 nm for single-pass scheme and 132 nm for the double-pass one, respectively, which are both over the whole conventional band and long-wavelength band. The ripple on the matching response can keeps less than 0.2 dB as well.

Introduction

Wavelength converters based on second-order, $\chi^{(2)}$, nonlinear optical effect are important photonic devices being researched for wavelength division multiplexing (WDM) networks. These devices can be realized by difference frequency generation (DFG) or cascaded second-order processes in nonlinear-optical waveguides and can take advantage of quasi-phase matching (QPM) by reversing the ferroelectric domains to improve the conversion efficiency using the largest available nonlinear coefficient in a crystal[1, 2]. Moreover, ultrafast response, complete transparency, and the simultaneous up- and down-conversion of multiple channels can be realized. The simplest approach to wavelength conversion of signals near 1.55 μm relies on DFG from an intense pump wave in the 700- to 800-nm range outside the telecommunication band[3]. However, it is difficult to couple pump and signals into the fundamental guided-wave mode simultaneously without exciting higher-order modes which are not involved in the wavelength conversion process. This problem can be avoided in the cascaded second-harmonic generation (SHG) and DFG scheme since both the input pump and signals are in the 1.5 μm band and thus can be easily launched into a waveguide together[1]. Two kinds of configuration are employed to realize cascaded SHG+DFG wavelength conversion, which one is called single-pass since the second-harmonic (SH) wave propagates through the waveguide once, and another is called double-pass due to the SH wave propagates twice in the waveguide.

For multichannel conversion in WDM systems, the bandwidth is expected to be broad and flat. However, in uniform QPM gratings, the signal conversion bandwidth and the pump detuning bandwidth are very limited. Fortunately, chirped or segmented gratings, as well as phase shift method were theoretically proposed and/or experimentally realized to broaden the QPM bandwidth[1-5]. Almost all of the investigations, however, focused on how to widen the bandwidth efficiently, thus the response flatness, which is also an important quality parameter for the wavelength converters, is then neglected. In this paper, the step-segmented grating is used to flatten conversion efficiency response in single- and double-pass cascaded SHG + DFG wavelength conversion. Large signal bandwidth can be obtained simultaneously.

Theory and model

The device is proposed as a titanium diffused optical waveguide in a Z-cut lithium niobate crystal wafer, supporting only X-propagating quasi-TM mode at 1.55 m. With the slowly varying envelope approximation, the coupled-mode equations for single-pass configuration are expressed as

$$\frac{\partial E_p}{\partial x} = -i\omega_p \kappa_{SH} E_p^* E_{SH} \exp(-i\Delta k_{SH} x) - \frac{\alpha_p}{2} E_p , \tag{1a}$$

$$\frac{\partial E_s}{\partial x} = -i\omega_s \kappa_{DF} E_c^* E_{SH} \exp(-i\Delta k_{DF} x) - \frac{\alpha_s}{2} E_s , \tag{1b}$$

$$\frac{\partial E_c}{\partial x} = -i\omega_c \kappa_{DF} E_s^* E_{SH} \exp(-i\Delta k_{DF} x) - \frac{\alpha_c}{2} E_c , \tag{1c}$$

$$\frac{\partial E_{SH}}{\partial x} = -i\omega_p \kappa_{SH} E_p^2 \exp(i\Delta k_{SH} x) - i\omega_{SH} \kappa_{DF} E_s E_c \exp(i\Delta k_{DF} x) - \frac{\alpha_{SH}}{2} E_{SH} , \tag{1d}$$

where E_p, E_s, E_{SH}, E_c are the field amplitude of pump wave, signal wave, second-harmonic wave and converted wave, respectively, α_i (i = p, s, c or SH) is the propagation loss of ω_i . $\kappa_{SH} = d_{eff}\sqrt{2\mu_0} / \sqrt{CS_{SH}N_p^2 N_{SH}}$ and $\kappa_{DF} = d_{eff}\sqrt{2\mu_0} / \sqrt{CS_{DF}N_S N_C N_{SH}}$ are the nonlinear coupling constants, where N_i is the modal index at ω_i, C is the light speed in vacuum and $d_{eff} = (2/\pi)d_{33}$ is the effective value of the nonlinear coefficient and d_{33} of lithium niobate is $\approx$ 27 pm/V. Moreover, S_{SH} and S_{DF} are the effective interaction areas for SHG and DFG and are found to be $S_{SH} \approx S_{DF} \approx 47$ μm^2. The phase-mismatched terms for each segment L_l are $\Delta k_{SH} = \beta_{SH} - 2\beta_p - 2\pi/\Lambda_l$ and $\Delta k_{DF} = \beta_{SH} - \beta_s - \beta_c - 2\pi/\Lambda_l$, where Λ_l (l = 1, 2,…, m) is the QPM poling period of the l-th segment.

In double-pass SHG+DFG scheme, the processes of SHG and DFG are separated and, hence, their solutions can be dealt with independently. The SHG process is expressed as the following coupled equations:

$$\frac{\partial E_p}{\partial x} = -i\omega_p \kappa_{SH} E_p^* E_{SH} \exp(-i\Delta k_{SH} x) - \frac{\alpha_p}{2} E_p , \tag{2a}$$

$$\frac{\partial E_{SH}}{\partial x} = -i\omega_p \kappa_{SH} E_p^2 \exp(i\Delta k_{SH} x) - \frac{\alpha_{SH}}{2} E_{SH} . \tag{2b}$$

The DFG process is expressed as

$$\frac{\partial E_s}{\partial x'} = -i\omega_s \kappa_{DF} E_c^* E_{SH'} \exp(-i\Delta k_{DF} x') - \frac{\alpha_s}{2} E_s , \tag{2c}$$

$$\frac{\partial E_c}{\partial x'} = -i\omega_c \kappa_{DF} E_s^* E_{SH'} \exp(-i\Delta k_{DF} x') - \frac{\alpha_c}{2} E_c , \tag{2d}$$

$$\frac{\partial E_{SH'}}{\partial x'} = -i\omega_{SH'} \kappa_{DF} E_s E_c \exp(i\Delta k_{DF} x') - \frac{\alpha_{SH'}}{2} E_{SH'} , \tag{2e}$$

where the range of x' is from L to 0, and the subscript SH' denotes backward propagation of the second harmonic wave. The poling period of step-segmented gratings is arranged as shown in Fig. 1. For the first section, the period $\Lambda_1 = \Lambda_{SHG} + \delta\Lambda$, where Λ_{SHG} is calculated by finding the effective indexes of waveguides after using the Sellmeier expression for $LiNbO_3$ when $\Delta k_{SH} = 0$, and $\delta\Lambda$ is the period shift to control the period changing of the first section. The grating period of other sections changes according to $\Lambda_i = \Lambda_{i-1} + \Delta\Lambda$, where $\Delta\Lambda$ is the constant period change between two adjacent sections. Flat broadband response can be achieved by optimizing the poling period parameters $\delta\Lambda$ and $\Delta\Lambda$.

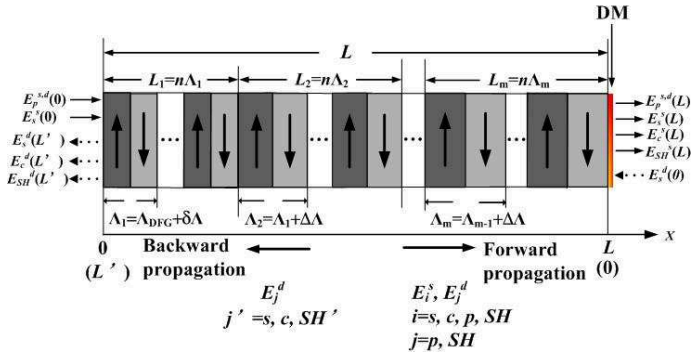

Fig.1 Model of step-segmented gratings for single-pass and double-pass cascaded SHG+DFG wavelength conversion. DM: dichronic mirror.

Results and discussion

High conversion efficiency, wide conversion bandwidth and flat response are needed for multichannel conversion in WDM systems. In this section, the step-segmented gratings is utilized and optimized to realize these characteristics. Neglecting the waveguide loss, optimal results of the conversion efficiency η and the 3-dB conversion bandwidth $\Delta\lambda_s$ for single- and double-pass schemes are calculated from equations (1)-(2) and shown in Fig. 2. Here the signal power is 1 mW, the pump is 100 mW at 1.55 μm, the waveguide total length is 3 cm. In the device, the response flatness is described by the difference between the maximum and center conversion efficiencies within the bandwidth. In order to achieve flat matching response, the fluctuation between the maximum conversion efficiency $\eta_{\max}$ and the center conversion efficiency η_0 is assumed less than 0.2dB (i.e., $\eta_{\max}-\eta_0<0.2$ dB).

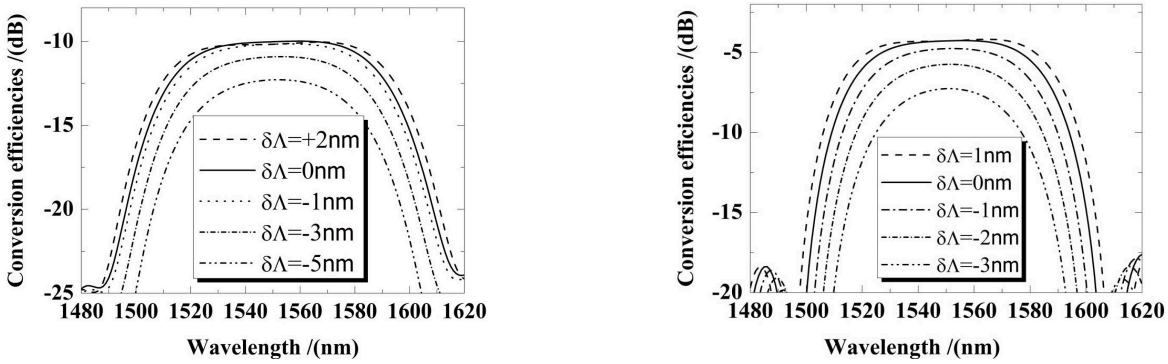

Fig.2 Conversion efficiency η and signal bandwidth $\Delta\lambda_s$ of (a) single- and (b) double-pass SHG+DFG scheme for uniform QPM structure with different $\delta\Lambda$.

It is easily seen Fig.2 that both the signal bandwidth $\Delta\lambda_s$ and the response flatness change with $\delta\Lambda$. The smaller the $\delta\Lambda$, the flatter the response and the smaller the $\Delta\lambda_s$. Under 0.2dB fluctuation assumption, the maximum $\Delta\lambda_s$ is 90 nm when $\delta\Lambda$ =+2 nm in single-pass scheme, while in double-pass configuration, that value is 80 nm when $\delta\Lambda$ =+1 nm. Although the signal bandwidth of double-pass is 10 nm less that of single-pass, the maximum conversion efficiency of the former of -4.26 dB is about 2 times greater than that of the latter.

Larger $\Delta\lambda_s$ can be obtained when dividing the nonlinear medium into 2 segments. Here both $\delta\Lambda$ and $\Delta\Lambda$ effect the conversion characteristics, as shown in Fig. 3. With the increase of $\delta\Lambda$ and $\Delta\Lambda$, $\Delta\lambda_s$ increases while the response flatness become worse. For 0.2 dB peak-to-peak ripple, 111nm signal bandwidth is obtained in single-pass scheme when $\delta\Lambda$ =3 nm and $\Delta\Lambda$ =-4 nm, while that value is 104 nm for the double-pass one when $\delta\Lambda$ =1 nm and $\Delta\Lambda$ =-1 nm.

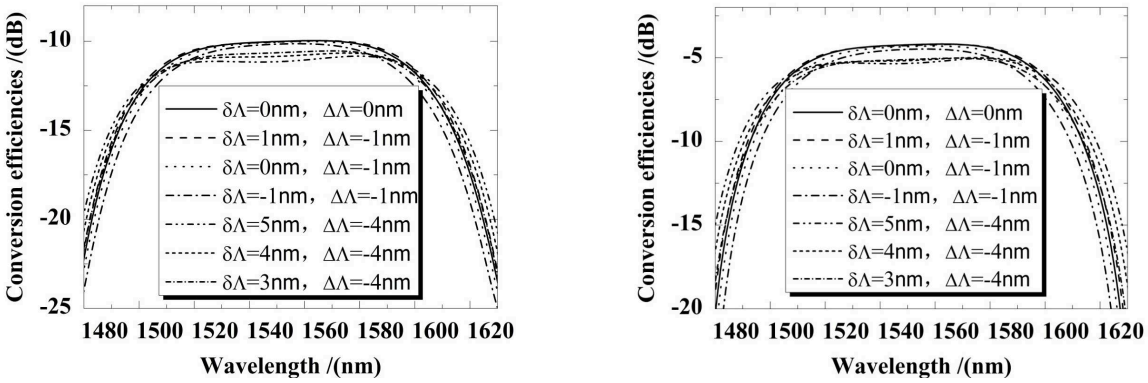

Fig.3 Conversion efficiency η and signal bandwidth $\Delta\lambda_s$ of (a) single- and (b) double-pass SHG+DFG scheme for two-step-segmented QPM structure with different $\delta\Lambda$ and $\Delta\Lambda$.

With the increase of the segment number, signal bandwidth can be widened further. If we divide the nonlinear medium into 3 segments, as shown in Fig. 4, $\Delta\lambda_s$ are 134 nm and 132 nm for single- and double-pass schemes, respectively. By comparison with Fig. 2 and Fig.3, adding segment number can efficiently broaden the signal bandwidth whereas rarely effect the maximum conversion efficiency.

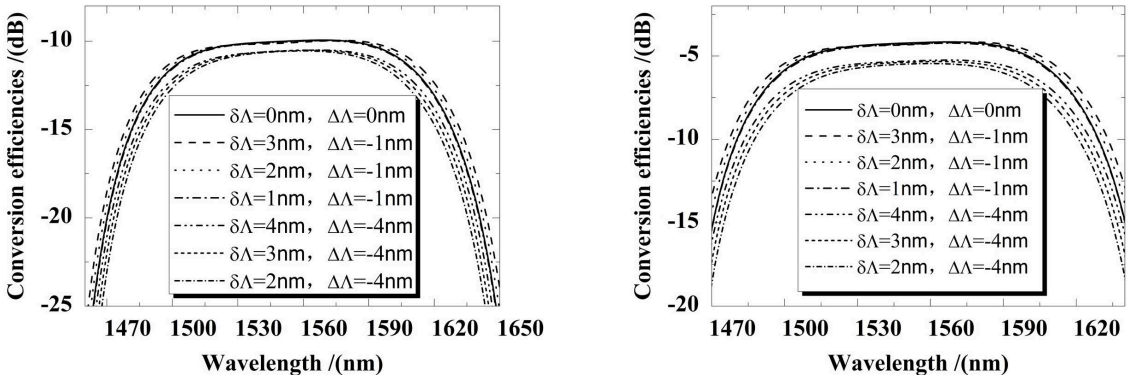

Fig.4 Conversion efficiency of three-step-segmented PPLN-based device versus (a) signal wavelength and (b) pump wavelength for different $\delta\Lambda$ and $\Delta\Lambda$.

Summary

The flat broadband wavelength converter for WDM application based on cascaded single-pass and double-pass SHG+DFG in step-segmented QPM waveguide has been analyzed numerically. The wavelength converter provides broader bandwidth and flatter response than uniform grating. In 3-cm-long three-segment channel waveguide, the signal bandwidths are 134 nm and 132 nm for single- and double-pass schemes, respectively. The ripple on the matching response keeps less than 0.2 dB simultaneously.

Keywords: Wavelength conversion, Quasi-phase matching, Difference frequency generation

Abstract. We report difference frequency generation-based wavelength conversion in step-segmented quasi-phase matched (QPM) gratings. It is shown that both the pump bandwidth and the signal bandwidth are efficiently widened by adding the segment number of QPM grating and optimizing the poling period of the first segment and the period shifts between adjacent sections. Especially, flattop conversion efficiency response with peak-to-peak ripples less than 0.2 dB, which is very helpful to multichannel conversion in WDM systems, can be achieved simultaneously. For 3-cm-long waveguide, the signal conversion bandwidth and the pump bandwidth reach 166 nm and 0.88nm, respectively, meanwhile the maximum efficiency is -0.55dB.

Introduction

Wavelength conversion is widely recognized as a key technology for future wavelength division multiplexed (WDM) networks and as an important method of enhancing routing optical network properties such as reconfigurability, nonblocking capability, and wavelength reuse[1]. Wave-mixing schemes due to second-order susceptibilities in QPM crystals are promising for all-optical wavelength conversion. They have ultrafast response and strict transparency. Difference-frequency generation (DFG) [2] and cascaded second-order interaction ($\chi^{(2)}$)[1, 3] are two important schemes to realize wavelength conversion in QPM crystals. The devices based on cascaded $\chi^{(2)}$ effect suffer from low conversion efficiency, because the effect consists of a second-harmonic generation (SHG) and a DFG processes. Direct DFG has high conversion efficiency in principle. However, it was difficult to couple pump and signals into the fundamental guided-wave mode simultaneously without exciting higher-order modes that are not involved in the wavelength conversion process. This problem can be solved by use of a subsequent adiabatically tapered periodic segmentation of channel waveguides [4].

In order to efficiently utilize the telecommunication band, flattened broadband wavelength converters are very attractive. However, in uniform QPM grating, the conversion bandwidth and the pump detuning bandwidth are very limited[1]. Many methods have been reported to broaden the bandwidth by chirping the optical superlattice period. By utilizing segmented gratings, Liu[1] obtained enhanced conversion bandwidth and pump bandwidth. Gao[3] reported a flat broad-band wavelength conversion in sinusoidally chirped optical superlattices (SCOS). However, the response flatness, which is also an important quality parameter for wavelength conversion as the bandwidth is, is a little worse in the above schemes. In this paper, step-segmented grating is used to fulfill wavelength conversion with high conversion efficiency, flat response and broad bandwidth.

Theory and model

In order to increase the conversion bandwidth and pump detuning bandwidth and enhance the flatness of response with high conversion efficiency, the step-segmented grating is employed in DFG-based wavelength conversion, as shown in Fig. 1. The Ep, Es, Ec in Fig. 1 are the field amplitude of pump wave, signal wave and converted wave, respectively. The step-segmented grating is implemented in a Z-cut and X-propagating lithium niobate channel waveguide, and it is formed by dividing the

nonlinear medium into *m* segments along *x* direction. The poling period of the first section is $\Lambda_1 = \Lambda_{DFG} + \Delta\Lambda_1$, where Λ_{DFG} is calculated by finding the effective indexes of waveguides after using the Sellmeier expression for $LiNbO_3$ when $\Delta k_{DF} = 0$[5], and $\Delta\Lambda_1$ is the period shift to control the period changing of the first section. The grating period of other sections changes according to $\Lambda_i = \Lambda_{i-1} + \Delta\Lambda_2$, where $\Delta\Lambda_2$ is the constant period change between two adjacent sections. Flat broadband response can be then achieved by optimizing the poling period parameters $\Delta\Lambda_1$ and $\Delta\Lambda_2$. In DFG wavelength conversion scheme, the signal wave and pump wave are injected from the same end of the waveguide and then propagate forward. The converted wave which carries is generated during the forward propagation by DFG process. With the slowly varying envelope approximation, DFG interaction can be described by the following nonlinear coupled-mode equations:

$$\frac{\partial E_s}{\partial x} = -i\omega_s \kappa_{DF} E_c^* E_p \exp(-i\Delta k_{DF} x) - \frac{\alpha_s}{2} E_s \tag{1}$$

$$\frac{\partial E_c}{\partial x} = -i\omega_c \kappa_{DF} E_s^* E_p \exp(-i\Delta k_{DF} x) - \frac{\alpha_c}{2} E_c \tag{2}$$

$$\frac{\partial E_p}{\partial x} = -i\omega_p \kappa_{DF} E_s E_c \exp(i\Delta k_{DF} x) - \frac{\alpha_p}{2} E_p \tag{3}$$

where α_i ($i = p$, s or c) is the propagation loss of ω_i. $\kappa_{DF} = d_{eff}\sqrt{2\mu_0} / \sqrt{CS_{DF}N_S N_C N_{SH}}$ is the nonlinear coupling constants, where N_i is the modal index at ω_i, C is the light speed in vacuum and $d_{eff} = (2/\pi)d_{33}$ is the effective value of the nonlinear coefficient and d_{33} of lithium niobate is ≈ 27 pm/V. Moreover, S_{DF} is the effective interaction areas for DFG and is found to be S_{DF} ≈47 μm^2. The conversion efficiency is defined as the ratio of the converted signal power with respect to the input signal power.

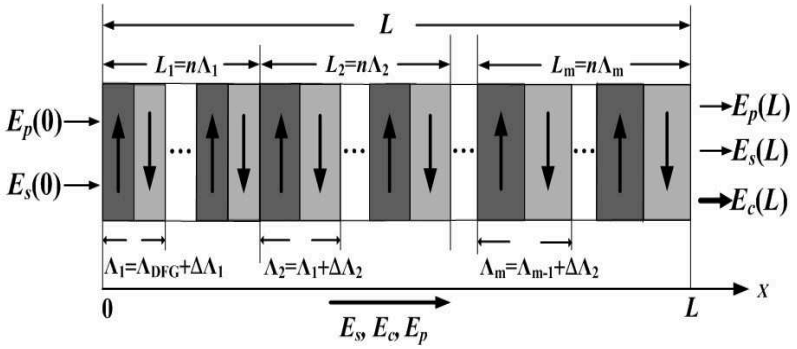

Fig.1 Schematic of the step-segmented structure.

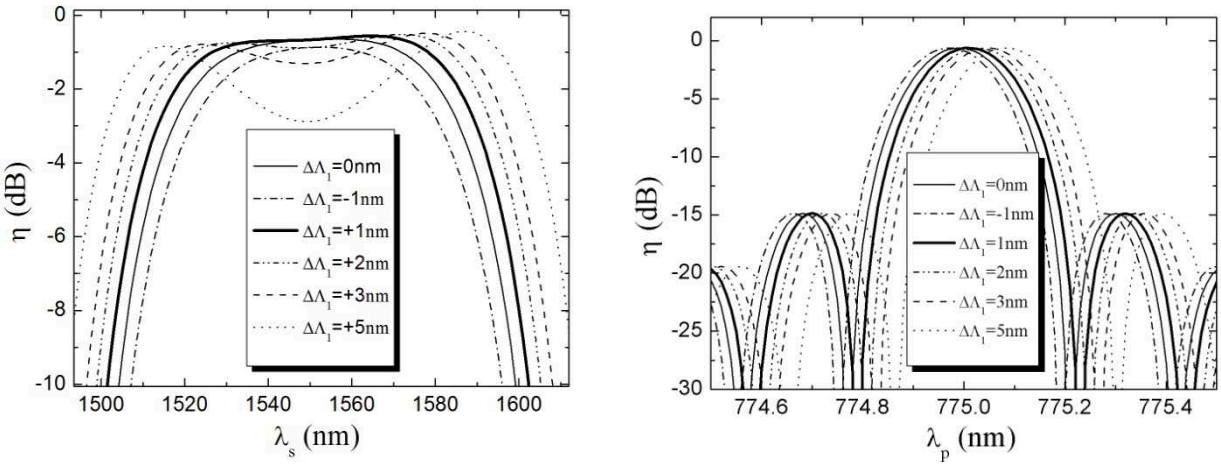
Results and discussion

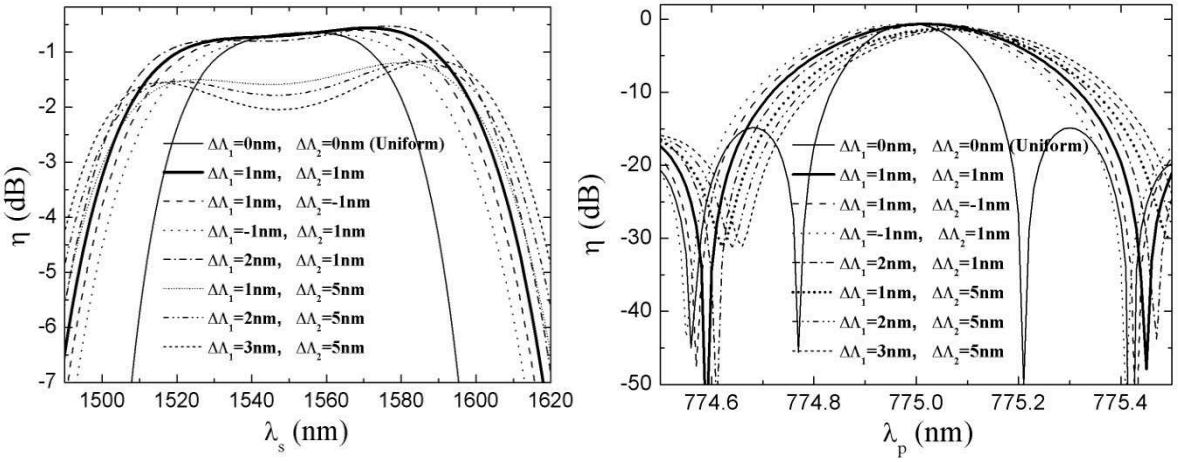
Neglecting the waveguide loss, Fig. 2, which comes from the calculation of equations (1)-(3), shows the optimal results of the conversion efficiency η, the 3-dB bandwidth of the signal and the pump in uniform QPM grating, respectively. Here the signal power is 1 mW, the pump is 100 mW at 0.775 μm, the waveguide total length is 3 cm. In the device, the response flatness is described by the difference between the maximum and center conversion efficiencies within the bandwidth. In order to achieve flat matching response, the fluctuation between the maximum conversion efficiency $\eta_{\max}$ and the center conversion efficiency η_0 is assumed less than 0.2dB (i.e., $\eta_{\max} - \eta_0 < 0.2$ dB).



(a) (b)

Fig.2 Conversion efficiency of one-segment PPLN-based device versus (a) signal wavelength and (b) pump wavelength for different $\Delta\Lambda_1$.

It can be seen from Fig.2 (a) that both the signal bandwidth $\Delta\lambda_s$ and the response flatness change with $\Delta\Lambda_1$. Under 0.2dB fluctuation assumption, $\Delta\Lambda_1$ =+1nm is recommended because $\Delta\lambda_s$ can reach its maximum value 81nm under this condition. From Fig. 2 (b), one can seen that the pump bandwidth $\Delta\lambda_p$ =0.19 nm, which is remains unchanged when $\Delta\Lambda_1$ changes.

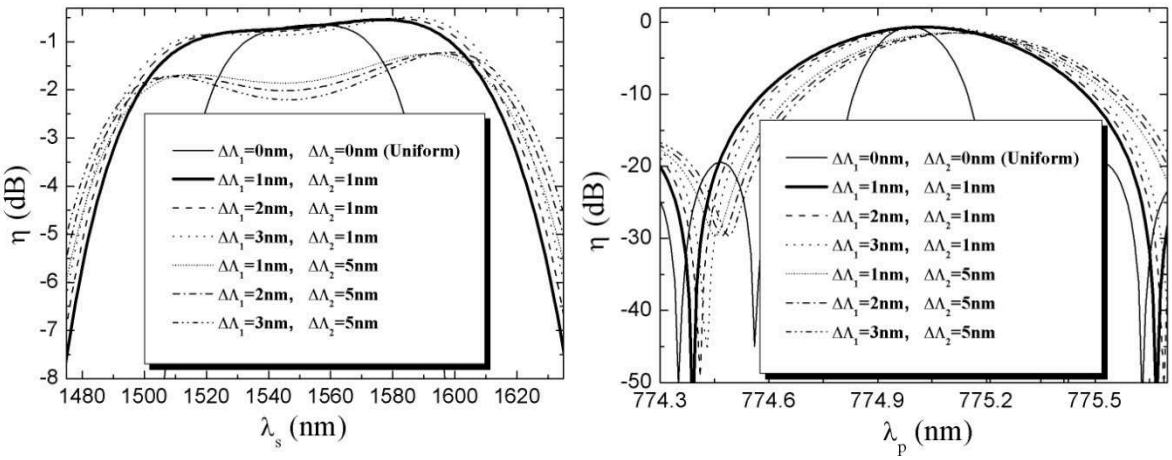


(a) (b)

Fig.3 Conversion efficiency of two-step-segmented PPLN-based device versus (a) signal wavelength and (b) pump wavelength for different $\Delta\Lambda_1$ and $\Delta\Lambda_2$.

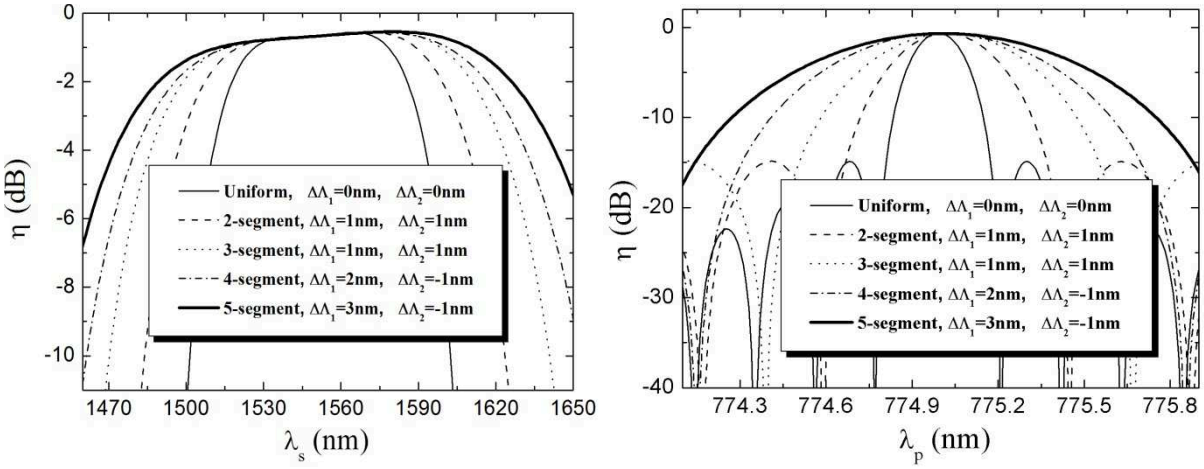
When dividing the nonlinear medium into 2 segments and optimizing $\Delta\Lambda_1$ and $\Delta\Lambda_2$, both $\Delta\lambda_s$ and $\Delta\lambda_p$ can be broadened, as shown in Fig. 3. With the increase of $\Delta\Lambda_1$ and $\Delta\Lambda_2$, $\Delta\lambda_s$ increases while the response flatness become worse. For 0.2 dB peak-to-peak ripple, 111nm signal bandwidth and 0.34 nm pump bandwidth are obtained when $\Delta\Lambda_1$=1nm and $\Delta\Lambda_2$=1nm.

Both $\Delta\lambda_s$ and $\Delta\lambda_p$ can be further widened with the increase of the segment number. It can be seen from Fig. 4 that if we divide PPLN into 3 segments, $\Delta\lambda_s$ and $\Delta\lambda_p$ are 134 nm and 0.54 nm, respectively, which are 53 nm and 0.34 nm larger than those of uniform grating structure. As shown in Fig. 5, when the segment number increases to 5, $\Delta\lambda_s$ and $\Delta\lambda_p$ reach 166nm and 0.88 nm, respectively, which are not only greater than those of SCOS-based wavelength conversion[3] but also larger than those of segmented grating-based wavelength conversion[1]. Moreover, the 0.2 dB flatness obtained in step-segmented gratings in this paper is better than the above two kinds of QPM structure as well.



(a) (b)

Fig.4 Conversion efficiency of three-step-segmented PPLN-based device versus (a) signal wavelength and (b) pump wavelength for different $\Delta\Lambda_1$ and $\Delta\Lambda_2$.



(a) (b)

Fig.5 Conversion efficiency versus (a) signal wavelength and (b) pump bandwidth for one- to five-step-segmented grating structures.

Summary

The flat broadband wavelength conversion based on DFG in step-segmented QPM waveguide is investigated. Both the signal bandwidth and the pump bandwidth can be efficiently broadened by increasing the segment number of QPM grating and optimizing the poling period of each segment. The ripple on the matching response of 0.2 dB is very small as well. Take 3-cm-long waveguide for example, the signal and pump bandwidths for five-segment step-segmented grating are 166 nm, 0.88 nm, respectively.

Keywords: Color Image; Enhancement; Wavelet Decomposition; Homomorphism Decomposition.

Abstract. In order to improve the ensemble of color image, this paper proposes homomorphism decomposition—wavelet enhancement algorithm based on the basic principle of Wavelet Transform. We separate the incidence component and reflection component of the image by homomorphism decomposition, and then combine wavelet transform to enhance image as well as reserve details. The experimental result shows that the adaption and effect is obviously superior to MSRCR.

Introduction

Image enhancement based on wavelet Transform is still in exploratory stage in current picture processing research. Some scholars at home and abroad have begun to reach this method. Wavelet decomposition and composition included in image enhancement of wavelet analysis lead to huge data size and long operation time. Thus, in practical application, especially in real-time system, it doesn't gain acceptance and promotion, but this doesn't mean wavelet analysis is unsuitable for image enhancement. Because of the irreplaceable superiority of wavelet analysis, the processing result is much more satisfying comparing to the traditional methods. With the improvement of algorithm and successful development of high-speed chip, the speed problem can be solved. Therefore, image enhanced by wavelet analysis well gain attention and application. This paper introduces the true color image enhancement algorithm based on wavelet transform, defining a new incidence and reflection model by static wavelet transform and proposing a new thought that image enhancement is a process of image energy decaying and reamplifying. There are no restrictions for true color needs enhancing, and the adaptation and effect is obviously superior to MSRCR.

Basic Principles of Wavelet Analysis

The basic thought of wavelet transform is expressing or approaching signals by a family of functions, which is called wavelet function. It is constituted by wavelets generated by scaling and translating a small wave of generating functions. The original signals are described by its transformation coefficient.

A family of discrete wavelet functions $\{\phi_{i,j}(x) = 2^{j/2}\phi(2^j x - k)\}_{j,k\in z}$ we get by scaling and translating Function ϕ constitute the orthonormal basis of integrable function space L2(R). Admissible wavelet ψsatisfying the constraint condition $\int \frac{|\phi(w)|^2}{w} dw < \infty$ has enough decay rate with mean value of 0, then the wavelet transform is

$$W_\phi f(a,b) = < f, \phi_{a,b} > |a|^{-1/2} \int_R f(t)\phi(\frac{t-b}{a})dt \quad (1)$$

Map function f to the sequence in Z2 and if conversion has inverse, we can set up the figure method of accurately reconstructing f from wavelet coefficient < f，ψa，b>.

According to the Mallat pyramid decomposition algorithm, we can achieve the rapid decomposition of separable two-dimension orthogonal wavelet by utilizing biorthogonal filter with ∑hn=1，∑gn=0. Cj-1 is low-frequency image, namely the smooth version of pending image; DHL, DLH, DHH is high-frequency image, namely the detail version of original version; and different decomposition layers Dj-1, Dj corresponds to different resolution ratio, among which DHL is horizontal operation for original image, DLH is vertical operation, DHH is diagonal operation and the detail images are

separately obtained by original image passing high pass and low pass filter. j is the wavelet decomposition level. The number of levels of wavelet decomposition can be selected by needs, and each level corresponds to different frequency band and resolution ratio: the smaller the dimension is, the higher the resolution ratio can be. Rough resolution ratio corresponds to the main outline of the image and detail resolution ratio to some specific form.

Enhancing True Color Image by Homomorphism Decomposition---Wavelet

Color Retention the Selection of Color Coordinate System： The paramount consideration of enhancing true color image is color retention before and after enhancement. Most scholars' research fail to consider the sensibility human vision to spectral (namely that the sensibility human eye to visible light spectral is uneven), namely fail to consider the human visual system spectrum sense quality. What's more, the enhancement effect image enhancing method with well physical explanation to true color image is not very good and needs improvements.

HSV color coordinate system separates T Hue, saturation and value. Channel H can be keep the same; the energy of the saturation of Channel S can be adjusted by human visual system spectrum sense quality to suit human version. Conduct image enhancement to Channel S by homomorphism decomposition and wavelet transform.

Saturation Adjustment Algorithm and Homomorphism Decomposition -- wavelet Enhancing True Color Image： As for the scene with wild illumination space variation, human eyes can adjust automatically and is highly adaptive; especially they can realize multi-scale recognition to the details. The multiresolution analysis in wavelet transform shares many similarities with the crystalline lens in human eyes. The application in image enhancement can reserve the details well, overcoming the detail loss in Retinex effectively.

We can separate the incidence component and reflection component; compress the dynamic range of reflection component and then composite the deposed incidence component and reflection component. Separate the incidence component and reflection component and we can get:

$$g \approx r_o^{rH} i_0^{iL} \quad (2)$$

We adopt high pass filter in separation. When rH=1, rL=0, the image after filtering only contains reflection component r0; when rH=0, rL=1, the image after filtering only contains incidence component i0. Thus the incidence component and reflection component are separated effectively.

The highlight section in the image mainly distributes in the low-frequency section. According to the quality of pupil and black granulocyte and the incidence—reflection model, image dynamic range can be compressed well by decaying the energy in low-frequency section (highlight section) of attenuation image, Figure 1 is the original image and Figure 2 is the Fourier energy spectrum diagram (The abscissa and ordinate in Figure 2 is the frequency sampling value. The ordinate is the Fourier Spectrum in Figure 1). We can see from Figure 2 that the energy of low-frequency section mainly distributed in the four angular points in the image. Therefore the utilization of low pass filter can decay the low-frequency energy in the image well.

Figure 1: Original Image

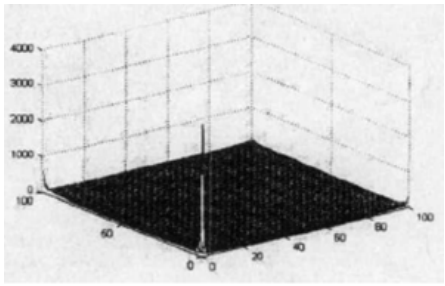

Figure 2: Spectrogram

The filtering effect of Butterworth low pass filter is well, as shown in Formula (3). In the formula, $D(u,v)=\sqrt{u^2+v^2}$ and rH are the coefficient of proportionalities; u, v are the frequency sampling value; D0 is the cut-off frequency and D0=1.2; the bigger n is, the more rapidly the decay rate of the filtering function is, and n=5. This low pass filter can enhance the wave form effectively.

$$H(u,v) = rHx\frac{1}{(D/D_0^2)^n + 1} \quad (3)$$

We can know from the incidence—reflection model that the compressed image within dynamic range can be get by multiplying the enhanced incidence component with reflection component. Because of the attenuation of the low-frequency energy, the overall brightness of the image is relatively dark, but we can conduct gamma correction by picture brightness formula（4）till the eyes feel comfortable. $\alpha = 0.35$, and the specific flow chart of homomorphism decomposition and wavelet decomposition image enhancement is shown in Figure 3.

$$g = g^{\alpha} \quad (4)$$

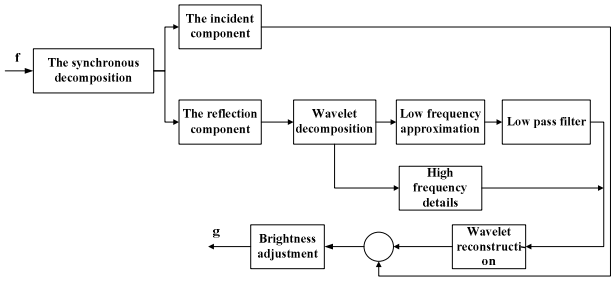

Figure 3: Image Enhancement of Homomorphism Decomposition and Wavelet Decomposition

The image color is determined by the wave length and frequency spectrum of catoptric light. Saturation reflects color category and chroma reflects shade, which is determined by color as well as the wave length and frequency spectrum of catoptric light. The sensibility of human to different spectrum is different as long as the catoptric light spectrum is different. Generally, human can sense the spectrum of wave length from 380nm to 780nm.

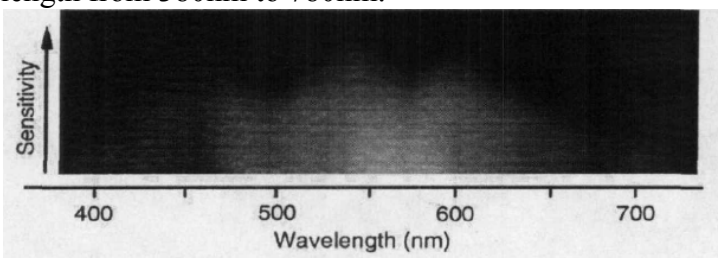

Figure 4: Human Visual System Spectral Sensibility Feature

From Figure 4, human most sensitive spectrum is between 425nm to 650nm; mainly the main colors are blue, green and light red. Frequency spectrum in other bands, namely the dark red, cannot be recognized easily. If the blue, green and light red dominate the true color image, the chroma and saturability can stay the same when enhancing, while if dark red dominates, dark red will turn into light red by adjusting saturation channel in formula (4) , which is good for observation.

$$H(u,v) = rH \times \frac{1}{1 + (\sqrt{u^2 + v^2} / D_0)^n} \quad (4)$$

rH is the proportionality coefficient determined by human eye observation, and we can select different rH to adjust the color purity of enhancement image.

Algorithm steps are as follows:

(1) read-in true color image;

(2) transform the true color image from RGB space into HSV space;

(3) enhance the true color brightness channel by Figure 3;

(4) saturation stays the same with blue, green and light red dominate; and adjust the image saturation by formula (4) if dark red dominates.

(5) the enhanced true color image will transform from HSV space to RGB space.

Example Verification

True color image enhancement of multiscale Retinex with color restore (msrcr) is the significant development of Retinex theory, and it is also one of the new-emerging classic algorithms of true color image enhancement. Thus, we conduct contrast experiment between the method in this paper and msrcr, and the experimental result is shown as follows:

Figure 5: Original Image

Figure 6: Image processed by msrcr

Figure 7: Image Enhanced by This Method

From the contrast experiment we can see that msrcr enhancement shows a lot halo and serious bleaching and loss details. The method in this paper is superior to msrcr in dynamic range compress, detail reserve and color maintaining. The image enhanced by this method is beautifully colored and is more close to the original color with moderate dynamic range comparing to msrcr. What's more, the application of human visual system spectrum sense quality moderately expands the spectrum sensitive range of human vision. True color images that enhanced by msrcr show obvious distortion. Observing the image border details after enhancement by these two methods, we can see that detail maintain of this method excel msrcr obviously. The true color image enhanced by this method is more suitable for human visual sense. It realizes the color constancy and the enhanced true color image is neat and clear. We cannot sense the halo and bleaching in human eye. The dynamic range compress, color and details maintaining is superior to msrcr.

Conclusion

From color constancy and the physical and spectroscopy qualities of true color image, we can get that the high dynamic of true color image is determined by the brightness. Separating brightness and color can reduce the impact on color when enhancing. Wavelet—energy enhancement has wide adaptation. It is flexible and the parameters can be adjusted according to needs and objective environment. The experimental result shows that this method is superior to MSRCR in maintaining color and details, removing bleaching and halo, and image clarity after enhancing.

Accurate detection of fault signal in large-scale communication

Shu Na

Chongqing University of Posts and Telecommunications shuna@cqupt.edu.cn 400065

Keywords: fault signal; data mining; fault detection;

Abstract: Deep data-mining methods of fault signal in large-scale communication system are researched. Although with the characteristic of frequency uniformity as signals distribute in each reaction zone, common method of fault signal detection based on shortwave dispersing is invalid employing in large-scale communication system, which presents the absence or instability of fault signal. For this reason, a method based on particle swarm optimization is proposed for fault signal detection in large-scale communication system. As reaction speed and activity scope within the whole particle swarm are replaced, accurate results are achieved. Taking particle swarm optimization, it is detected that whether there is a fault in communication systems. The experimental results show that proposed method in signal fault detection process can greatly increase accuracy of signal fault detection, as plays a greater role in future.

1 Introduction

As fault detection techniques plays irreplaceable role in many fields, such as mechanic, electricity and control and has become core problem in exploring communication field [1]. For fault detection in large-scale communications systems, detection are achieved by comparison of fault signals collected in communication [2]. Fault signal detection has been the focal point of communication research and gotten attention of many researchers [3-5]. Currently fault signal detection methods are widely used, including PSO-based neural network algorithm, local wave analysis algorithms and wavelet decomposition algorithm [6]. Due to broad development of fault signal detection method in communication, it has become a major topic of inquiry for many experts with great prospects.

2 fault signal detection method

2.1 Particle update process

When a communication failure is detected, it must employ signal of all communication state as the particles. According to particle analysis, a communication failure is realized. Updating the particle, focus calculation of velocity and diffusion activities for particles are performed as Equation (1):

$$\begin{aligned} &x_k(m+1) = \xi x_k(m) + e_1 t_1 (R_k - Z_k(m)) \\ &+e_2 s_2 \left(R_i - Z_k(m)\right) \\ &Z(m+1) = Z_k(m) + x_k(m+1) \end{aligned} \tag{1}$$

In the process of updating the particles, the optimal particle swarm will find the optimal particle while speed and operating range of particle swarm are fully replaced and make it the optimal particle. The purpose of the non-optimal PSO is to find the operating range of other particles and then update the data.

Applying the above method, traveling range of other particles in the optimal particle swarm is obtained. By updating range, inconsistent occurs between updated range and activities range of optical particle swarm. Using equation (2) particle outside the optimal particle swarm can be updated:

$$\begin{aligned} &y_l(n+1) = \xi x(m) - e_1 t_1 \left(R_K - Z_K(M)\right) \\ &-e_2 t_2 \left(R_i - Z_K(M)\right) \end{aligned} \tag{2}$$

Employing above process, update process of optimal particle is completed. The particles become ideal value of the entire operating region, whose value are used to detect communication failures.

2.2 Achievement of communication signal detection

In the communication signal detection process, according to operating region and updated speed of optimum particle swarm, set the optimum area particle as b, $F_q > b$ shows activity range of optimal particles swarm are substantially the same and updating operation can be achieved so as to improve detection accuracy of communication failure signal.

When communication failure signal is in detection, optimal particle E_k is an enlarged particles appearing in the specified range, with the number of the particles is O. So the optimal and enlarged particles are combined to form a set of F. In this set, it is possible to obtain the optimal solution, employing transition between optimal particle and phase E_k. Then optimum value can be obtained in local range.

Assuming in communication particle swarm of fault signal the number of all particles is Q, the height of a single particle is N, using Equation (3) - (5) can calculate active area of particle swarm in communicate fault signal:

$$F_q = \frac{1}{1+G(Q)} \tag{3}$$

$$G(Q) = \frac{1}{N}\sum_{l=1}^{N} G_l(Q) \tag{4}$$

$$G_l(Q) = \sum_{j=1}^{P} -r_{kl} \log r_{kl} \tag{5}$$

All communication failure signal set is composed as set C, using the equation (6) it can be calculated for the k-th signal frequency of communication failure:

$$T(C_k) = \{T_l \,|\, 0 < \|C_k - T_l\| < t, T_l \in T\} \tag{6}$$

By the above methods, updated speed and activity scope of all particles in particle swarm are calculated to obtain the results, which are used as a basis for communication failure detection. Particle swarm updates to replace all the particles, as achieves fault signal detection in large-scale communication system.

3 Analysis of experimental results

To verify the feasibility and accuracy of proposed detection algorithm based on particle swarm optimization in large-scale communication system, an experiment is performed.

In the experiment, communication fault signal collected by a sensor is presented in Fig 1:

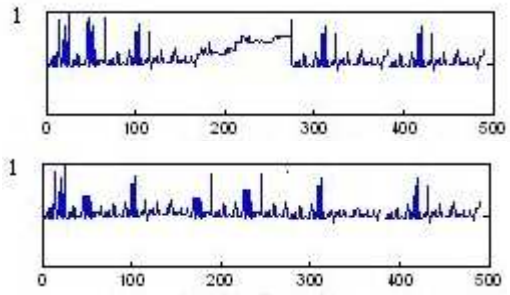

Fig1 Communication fault signal

Using the algorithm for detecting communication failure signal, the experimental results obtained are shown in Fig2:

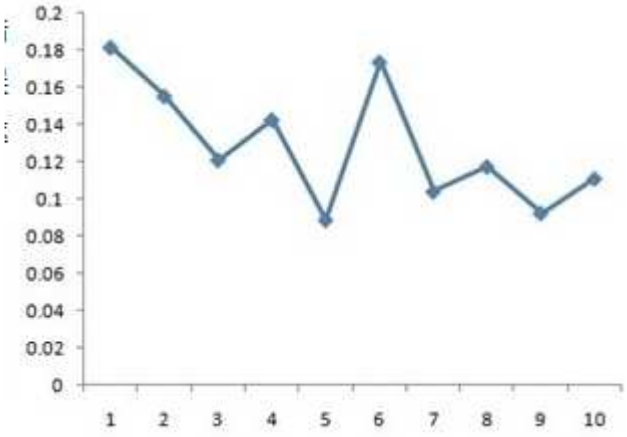

Fig2 Experimental results of communication fault signal

Analyzing with the above experimental results, it is possible to obtain the following table:

Table1 Experimental data of proposed algorithm

Experimental times	Correct judgment	Error judgment	Error rate（%）
1	33	6	0.181818
2	45	7	0.155556
3	33	4	0.121212
4	35	5	0.142857
5	45	4	0.088889
6	46	8	0.173913
7	48	5	0.104167
8	51	6	0.117647
9	54	5	0.092593
10	36	4	0.111111

Employing above experiment, the adopted algorithm for detection of communication fault signal can obtain accurate test results, which meets the communication requirements.

To verify the superiority of fault signal detection method proposed in this paper, traditional algorithms and improved algorithms are respectively performed for fault signal detection in large-scale communication system. Experimental results obtained are as follows:

Table2 Experimental data of different algorithms

Experimental times	Correct rate（%）	
	Traditional algorithm	Proposed algorithm
1	88	96
2	87	93
3	88	95
4	85	93
5	87	93
6	84	94
7	86	96
8	88	94
9	86	94
10	84	93

According to experimental results it is learned that proposed algorithm is performed for fault detection in large-scale communication system, detection accuracy is higher than traditional algorithms, demonstrating the superiority of the proposed algorithm.

4 Conclusion

Fault signal detection method in large-scale communication system is proposed based on particle swarm optimization. The reaction speed and activity scope of whole particles in particle

swarm are replaced, so that results of fault signal detection are accurate. Taking PSO method, it is demonstrated whether there is a fault in communication systems. The experimental results show that the proposed method in fault signal detection process can greatly increase accuracy of fault signal detection and will play a great role.

Keywords: WDM-PON, Coherent detection, Colorless ONU, Carrier contribution

Abstract. The wavelength division multiplexing passive optical network (WDM-PON) incorporated with colorless optical network units (ONUs) and centralized light source is the most promising approach for next generation PON. A cost-effective architecture utilizing coherent detection for upstream (US) signal is proposed to enlarge the reach of such WDM-PON systems. Simulation results show that a symmetric 10-Gbps WDM-PON with 80km error-free transmission is realized without using any optical amplifiers.

Introduction

WDM-PON has been considered as a promising candidate to meet the requirements of the future broadband access network solutions, owing to its advantages of broadband capability, free flexibility, and high energy efficiency etc [1]. To make the PON system cost effective and reduce the system maintenance cost, The WDM-PON using colorless ONUs with centralized light sources originated from the optical line terminal (OLT) is a desirable solution [2]. Furthermore, both downstream (DS) and upstream (US) transmission in a full duplex fashion using one single fiber is essential to further reduce the cost, complexity and size of WDM-PON plants [3]. However, the maximum reach of such a WDM-PON is often restricted by the power budget of the US signal. It seems to be possible to mitigate this limitation by increasing either the power of centralized light sources or the gain of US signal at ONUs. Unfortunately, signals propagating in opposite directions on the same wavelength in one single fiber suffer the impairment due to unavoidable Rayleigh backscattering (RB) and Fresnel back-reflections. Therefore, the backscattering noise will increasing proportionally, namely, the SNR of US signal will not be improved as expected [4].

Optical coherent detection technique has attracted great interest in the last decade for the prominent properties of its receiver sensitivity and frequency selectivity [5]. Thus, it may be possible to increase the maximum reach of WDM-PON by utilizing the coherent receiver. There have been some reports on using coherent technology in WDM-PON. But most of them are focused in using coherent receiver at both OLT and ONUs [6]. Although such proposals can increase the maximum reach of WDM-PON, the coherent detection at ONU requires local light source, therefore, the ONU is no longer cost-effective and colorless. Based on the fact that the maximum reach of WDM-PON is mainly determined by the US transmission, in this paper we propose a compromise architecture to realize long reach, single-fiber, full-duplex, centralized WDM-PON system incorporated with colorless ONU and coherent detection only for US signal, where 10-Gbps symmetric transmission are supported by quadrature phase-shift keying (QPSK) US signal and on-off keying (OOK) DS signal, respectively.

System Architecture

In general, carrier contribution [7] and remodulation [8] are the essential techniques to realize the colorless ONUs with centralized light sources. The principle of colorless ONU based on carrier distribution is shown in Fig. 1. Both DS and unmodulated carrier CW are transmitted towards the ONU in the single fiber on different wavelength. At ONU, they are separated by a demultiplexer

(DEMUX). Then the DS is demodulated by a PIN receiver, and CW is delivered by a circulator to the modulator through which the US data is loaded. The modulated CW (US signal) is transmitted again through the circulator, multiplexer (MUX), and towards OLT. Otherwise, in the remodulation-based WDM-PON , the DS signal and US signal are carried on the same wavelength, then the power of the DS signal is coupled to the receiver and reflective semiconductor optical amplifier (RSOA), respectively. The carrier for US transmission is recovered from DS signal by the saturated gain effect of RSOA. Meanwhile, the US data is modulated onto the recovered carrier in RSOA. Because of the reflection character of RSOA, the loop-back and circulator in Fig. 1 are no more used.

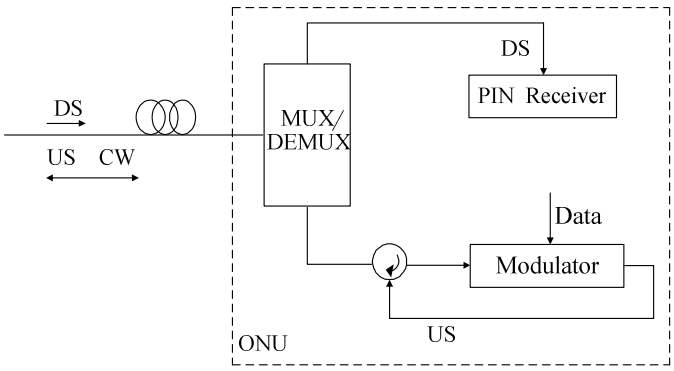

Fig.1. Principle of the colorless ONU based on carrier contribution

For both carrier contribution and remodulation, there is no extra local oscillator (LO) is needed if coherent detection is implemented at OLT. Although the complexity of the colorless ONU based on remodulatoin is a little simpler, and there is an enough margin in power budget because of the considerable gain of RSOA, the bit rate of US is hard to reach 10-Gbps due to the modulation nonlinearity of RSOA. In addition, the influence of Rayleigh backscattering noise is more serious if DS and US signals are at the same wavelength in the single fiber. For the above reasons, the carrier contribution technique is adopted in this paper to realize colorless ONU. Furthermore, the Mach-Zehnder modulator (MZM) is used to make the bit rate of US transmission up to 10-Gbps, which is important in the scenarios requiring symmetrical transmission.

The system architecture of proposed long-reach, bi-directional WDM-PON is shown in Fig. 2, where only one ONU is illustrated. The key features of the proposed scheme are (1) the upstream data is modulated onto distributed carrier using MZM at ONU, and (2) at OLT the US signal is demodulated by coherent detection without using extra LO.

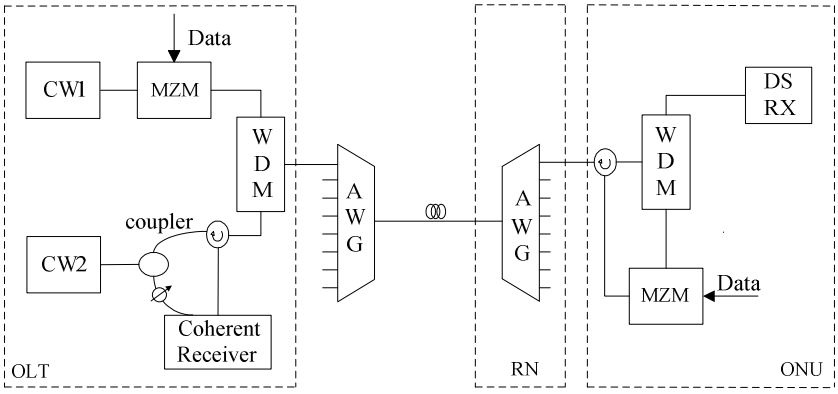

Fig.2. Schematic of the proposed long-reach centralized bi-directional WDM-PON using coherent detection for US transmission

At OLT, there are two continuous light sources (CW1, CW2) with different wavelengths. The MZM is used to generate the 10-Gbps OOK DS signal on CW1. A wavelength division multiplexer (WDM) is used to multiplex the DS signal with the distributed US carrier coupled the power from CW2 before they are passing an arrayed waveguide grating (AWG). After the AWG, the downstream

signal and the distributed US carrier are transmitted towards the ONU via remote node (RN) and a circulator.

At ONU, the WDM is used to separate the DS signal and distributed US carrier. Passing the WDM, DS signal is received by the downstream receiver (DS RX). The distributed US carrier is modulated 10-Gbps US data by a parallel MZM with the format of QPSK. The modulated US signal is then transmitted back to OLT. When the US signal reaches OLT, it passes through a WDM and a circulator, and then is delivered to the coherent receiver, where the undistributed part of CW2 acts the role of LO.

Results and discussion

The performance of the proposed system is simulated using Optisystem 8.0. In simulation system, the main parameters are set as following: The central wavelength of CW1, CW2 are 193.1THz and 193.2THz, respectively, and their linewidth is 0.1MHz. The standard SMF is used with loss and dispersion of 0.2dB/km and 16.75ps/(nm•km), respectively. Other parameters, such as the loss of WDM, AWG and MZM are default values in Optisystem 8.0. The optical power of distributed US carrier at the import of WDM is 2dBm, which is equal to that of modulated CW1. The US and DS data are pseudo-random sequences with length of 29-1 at the bit rate of 10-Gbps. No forward error correction and dispersion compensation are used in the simulation. Because the maximum reach of WDM-PON is limited by US transmission, here only the cases about US transmission are simulated and discussed.

The dependences of US transmission performance on the power of LO are simulated as shown in Fig. 3(a). It is obviously that the BER is decreased as expected when increasing the power of LO for any transmission distance. Even for error-free 80km transmission, the required LO power is still an available value of -2dBm.

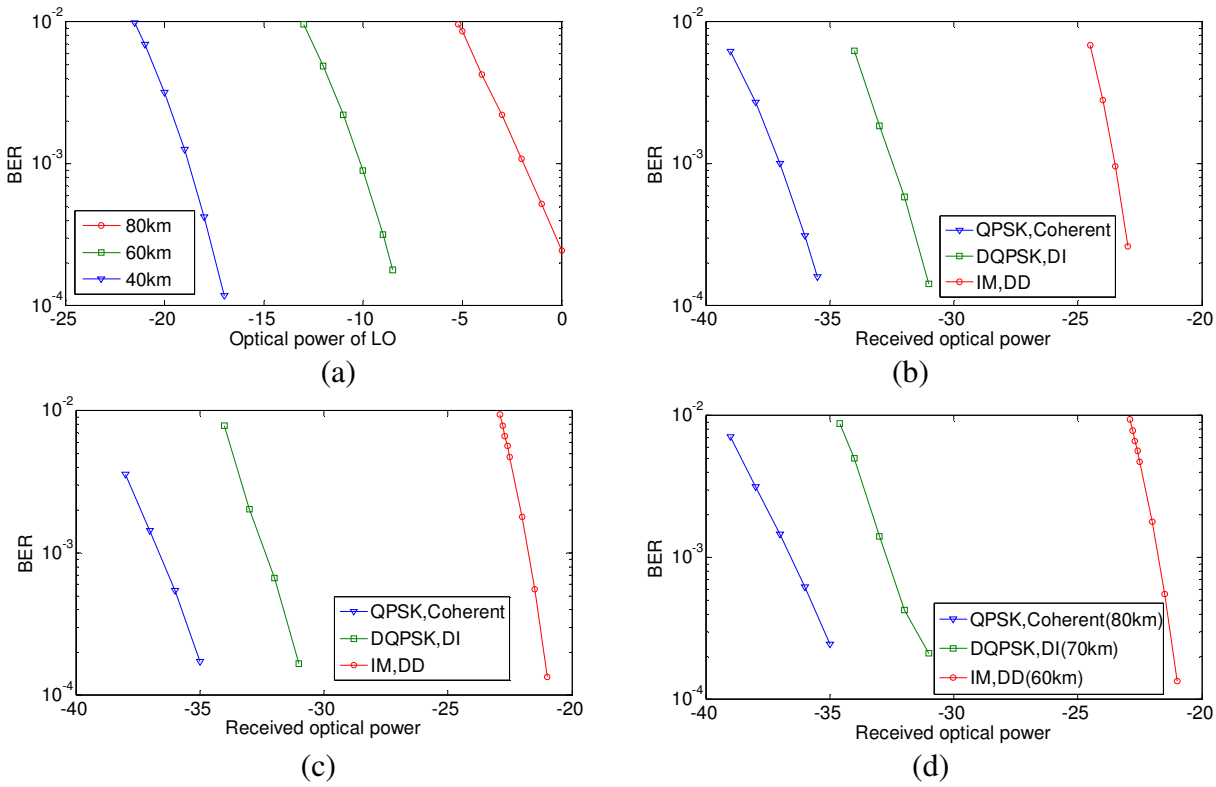

Fig.3. Simulation results of US transmission. (a) The dependences of BER on the power of LO. (b)-(d) BERs versus received powers of US signal for different modulation formats and detection techniques with the reach of 40km, 60km and 80km, respectively.

For comparison, the US transmissions of the WDM-PON using intensity modulation, direct detection (IM, DD) and DQPSK modulation, delay interferomenter based detection (DQPSK, DI) are also simulated here with the same simulation parameter sets. The simulation results under 40, 60, and 80km for US transmission are shown in Fig. 3(b), (c), and (d), respectively. The received power US signal is changed by the attenuator placed just in front of the coherent receiver and the power of LO is the constant value of -2dBm. For both 40km and 60km cases, it is found from Fig. 3(b) and (c) that the minimum allowed received power of coherent detection at BER=10-3 is 3~5dB and13~15dB lower than that of DI and DD, respectively. This will make an enough margin for power budget of the proposed WDM-PON. The maximum reaches supported by different detection schemes are also simulated as shown in Fig. 3(d). The maximum reach of IM-DD is about 60km, and DI can reach 70km. Otherwise, coherent detection can support 80km error free US transmission.

Summary

In this paper, a novel colorless ONU-based WDM-PON architecture is proposed to provide a long-reach, high speed US transmission by combing coherent detection with carrier contribution. The simulation results show that the maximum reach of error free transmission can over 80km with 10-Gbps QPSK US signal. Therefore, it provides a feasible approach to realize the symmetric WDM-PON with high bit rate (>10G-bps) and long transmission distance (>80km) without using any optical amplifiers.

Keywords: time frequency analysis; noise, signal extraction; network intrusion

Abstract. The illegal signal such as the intrusion signal which wanted to be embedded in the normal signal was analyzed for the extraction, and made the network environment be safe and pure, so the signal detection problem was shown as the key and important problem in the assurance of the safety of the network. The signal processing principle for the non stationary signal was analyzed firstly, and the new signal extraction method based on the Wigner Ville distribution and Hough transformation theory of the time frequency analysis. The original signal was filtered and detected, the spectrum analysis was got as the same time for the testing the detection property in the simulation. Simulation and experiment was implemented on the objects of the network intrusion signal with the real collection in the database. Simulation result shows that the performance of decreasing the noise and filtering is very good. The intrusion signal can be detected and extracted perfectly, and also it shows good value in the analysis of the network safety in practice.

Introduction

Facing the hackers attack means continuous hidden and sharp, the security threats of network system are increasing greatly, it is not enough to defeat the security threats just depending on the traditional firewall method. An effect Intrusion Detection System (IDS) needs be researched and the network security defense system needs to be studied and established for detecting and refuse the intrusion data for ensuring the network security[1,2]. Basically, the intrusion detection system is the application of the digital signal and information procession subject, and it is also the development and promotion of the signal and information procession subject in the modern network security subject. From the signal processing and data analysis point of view, the intrusion detection can be divided into two types as intrusion detection can be divided into expert knowledge of misuse detection and anomaly detection method[3]. The anomaly detection method is taken as the detection method in this paper, which based on the anomaly behavior detection method. Firstly, the normal behavior model system is built based on the mathematical method to detect the outlier pattern and abnormal model is going to be detected in the data by the anomaly detection method, and the anomaly model just is the intrusion feature[4,5].

In this paper, the detection problem of the network intrusion signal in deep camouflage is going to be analyzed in the signal analysis area, and it had become the problem of the signal extraction of the intrusion network signal in the interfering noise and is shown as the detecting, and filtering the signal. The illegal signal such as the intrusion signal which want to be embedded in the normal signal is analyzed for the extraction, and made the network environment be safe and pure, so the signal detection problem is shown as the key and important problem in the assurance of the safety of the network. The signal processing principle for the non stationary signal is analyzed firstly, and the new signal extraction method based on the Wigner Ville distribution and Hough transform theory of the time frequency analysis. The original signal is filtered and detected, the spectrum analysis is got as the same time for the testing the detection property in the simulation.

Non-stationary signal processing technology

A. Non-stationary signal

According to the many signal resources and disturbances, the signal is a non stationary signal including the network intrusion signal. The network intrusion signal is hiding in the common network signal which is referred as the interference noise. For extracting the intrusion signal, the

research and he application practice show that the statistics of the signal should be studied because it is playing an important role in the signal processing work.

The most common statistics are the mean value as the first-order statistics, and the correlative function, the power spectrum density (second-order statistics) and so on. If the joint distribution function of $\{x(t_1),\cdots x(t_n)\}$ and the joint distribution function of the $\{x(t_1+\tau),\cdots x(t_n+\tau)\}$ are equal for all the $t_1,\cdots,t_n$, and $\tau\in T$. The random process $\{x(t),t\in T\}$ is called strict stationary signal. It means that the distribution is constant with the change of time. If

$$E\{x(t)\}=m\in \mathrm{C},\quad \mathrm{E}\{\left|\mathrm{x(t)}\right|^2\}<\infty,\quad E\{[x(t)-m][x(s)-m]^*\}=R_x(t-s)-\left|m\right|^2 \tag{1}$$

Where $R_x(t-s)=E\{x(t)x^*(s)\}$, and the $x^*(s)$ is shown as the complex conjugate of $x(s)$, and the random process $\{x(t),t\in T\}$ is called generalized stationary process. A strict stationary process is always a generalized stationary process, and a generalized stationary process is not always shown as a strict stationary process. If a signal is not a generalized stationary process, then it is a non-stationary signal. The most common non-stationary signal is auto-correlative function and the power spectrum density.

B. Time frequency feature of the signal

The time frequency feature of the signal is researched for reflecting the intrinsic quality of the signal. In the time frequency analysis of the signal domain, the common features which can reflect the time domain and frequency domain information are including as follows: mean value of time, mean value of frequency, time distribution (standard deviation of time), and frequency distribution (standard deviation of frequency), the functions of them are shown as follows.

Principle of the time frequency analysis

Generally speaking, the Fourier transform is always used in the analysis and processing of the stationary signal, the Fourier transform algorithm is used as the signal processing method, and based on the Fourier transform, the signal can be analyzed both in the time domain and the frequency domain, the Fourier transform makes the signal which was shown in the time domain transferred in the frequency domain,, the Fourier transform is shown as follows:

$$S(f)=\int_{-\infty}^{\infty}s(t)e^{-j2\pi ft}dt \qquad s(t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}S(f)e^{j2\pi ft}df \tag{2}$$

Because of the survival of the noise, the performance of the signal processing such as the signal extraction and signal filtering is affected to a great degree. For meeting the demand of the conditions, the time frequency distribution of the constant signal $s(t)$ defined as:

$$P(t,f)=\int_{-\infty}^{\infty}s(u+\frac{\tau}{2})s^*(u-\frac{\tau}{2})\alpha(\tau,v)e^{-j2\pi(vt+f\tau-vu)}dudvd\tau \tag{3}$$

In the design of the time frequency distribution, the core function should be designed according to the real application.

Feature extraction algorithm in the sudden changing interference

The maximum value of the WVD on some moment is not the instant frequency value of the signal, then the instant frequency is a slow change function, the basic concept of the algorithm is come from the digital image processing subject, the principle of the algorithm is that the length of the toe points in the two dimensions of the interface is demanded to be minimum, considering the time interval $n\in[n_1,n_2]$, all the paths between n_1 and n_2 points belong to K. the instant frequency is the minimum path shown as follows:

$$\hat{\omega}(n)=\arg\min_{k(n)\in \mathrm{K}}[\sum_{n=n_1}^{n_2}g(k(n),k(n+1))+\sum_{n=n_1}^{n_2}f(WVD(n,k(n)))]=\arg\min_{k(n)\in \mathrm{K}}p(k(n);n_1,n_2) \tag{4}$$

Where the $p(k(n);n_1,n_2)$ is the sum of $g(x,y)$ and $f(x)$, and the $g(x,y)$ is the cost price function of n_1 to n_2 along with path $k(n)$. The function $g(x,y)=g(\left|x-y\right|)$ is non decreasing function for the $\left|x-y\right|$, and the $f(x)$ is non increasing function for the $x=WVD(n,k(n))$. Then the maximum value of WVD on some moment is the instant frequency value of the signal.

Where the M is the points number of the signal frequency, the function $f(x)$ is defined as:

$$f(WVD(n,\omega_j)) = j-1 \tag{5}$$

If $g(x,y) = const$ the maximum value of WVD on some moment is the instant frequency value of the signal in the formula (5), the minimum value which is determined by the function $f(x)$.the $g(x,y)$ is shown as linearity form.

Simulation results and analysis

In the simulations, the signal is going to be extracted with the new algorithm for the intrusion network signal with sudden changing noise interference, and the DARPA database is taken as the object of study, the database can represent the real network data and it contains abundant intrusion signal types. The detected network intrusion signal is selected as the detection objective in the DARPA database, the test time is from 12:00 AM to 18:00 PM. The simulation parameters are set as follows: the network intrusion signal is taken as the simulation objective and the normalization original frequency $f_1 = 0.3$, and the normalization stop frequency $f_2 = 0.05$. In the sudden changing interference and the SNR is -5dB. The network intrusion signal is extracted based on the time frequency analysis method. The useful signal information is got though WVD algorithm, it can be shown in the WVD result plot as a line in the axis. In this paper, the WVD and Hough transform are combined together to detect the LFM signal. According to the two groups of the intrusion signal, the filtering extraction results are showed in the Figure2 as follows.

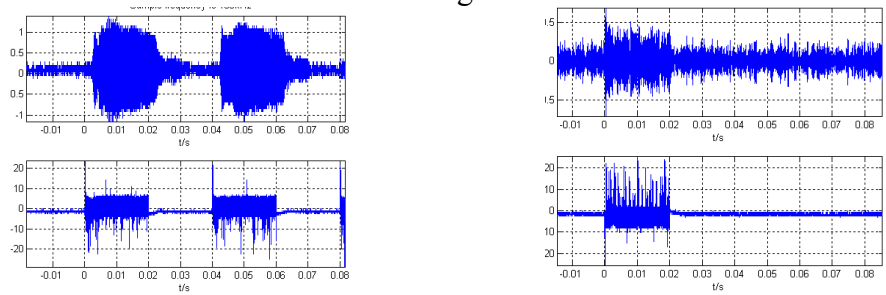

Figure1 Filtering result for the network intrusion signals

The WVD and Hough transform algorithm of the time frequency analysis method is proposed and simulated in the experiment, according to the collected network intrusion signal, the frequency spectrum is shown in the Figure 2. Where the SNR = -5dB. In the Figure 2, it is showing that there is massive interference information resulted from noise in the time and frequency interface, and there is a sharp peak shown as the power collection property. The spectrum figure shows that the signal is extracted and detected perfectly with nice performance.

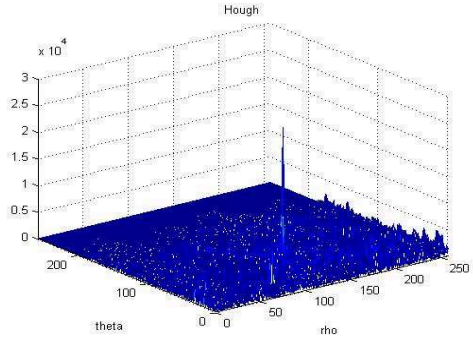

Figure 2 Signal extraction result based on WVD-Hough

Conclusions

In the paper, the signal detection and extraction problem of the network intrusion signal in deep camouflage was analyzed. Simulation and experiment was implemented on the objects of the network intrusion signal with the real collection in the database. Simulation result shows that the performance of decreasing the noise and filtering is very good in the interference of the sudden changed noise as the SNR is -5dB. The intrusion signal can be detected and extracted perfectly, and also it shows good value in the analysis of the network safety in the network safeguard application.

Keywords: communication network; abnormal data recognition; data mining; fuzzy C-means clustering

Abstract. The abnormal data of communication networks are complex and diverse, it is difficult to recognize and mine the abnormal data accurately and effectively with traditional methods. In order to improve the recognition accuracy of communication network, a data mining algorithms based on the method of communication network abnormal data recognition is presented. Firstly, the communication network data samples are analyzed for fuzzy c-means clustering in order to obtain the degree of membership matrix. Secondly, the training samples of communication network abnormal data mining are selected according to the membership. At last, the training samples are put into the least square support vector machine learning, which establish the model of abnormal data identification in communication network. The performance of the algorithm was tested by simulation tests, and the results show that, the abnormal data recognition efficiency and accuracy in this paper was improved much more than the traditional identification methods.

Introduction

With the development of information technology, communication network security problems have become more serious, mainly for network intrusion, communication secrets leak and information warfare. Abnormal data recognition was defined to extract the abnormal data from a large number of data. Abnormal data recognition of the communication network and the security characteristics of the communication network has an important role on the protection of national communication secrets[1].

The abnormal data recognition of the communication network can be divided into non supervision recognition methods and supervision recognition methods. Non supervision recognition methods include K-Means method, FCM method[2], and supervision recognition methods include maximum likelihood method, and it is a good solution to the contradiction between the learning accuracy and generalization ability, so more and more scholars begin to apply LSSVM to abnormal data recognition of the communication network[3]. But the communication network data is quite large. Therefore, the selection of training samples becomes a difficult problem in abnormal data recognition of the communication network. In normal circumstances, the communication network data samples need manual's participation, which prevents the application of the LSSVM in the abnormal data recognition of the communication network. In order to solve the problem, some scholars proposed to select training samples using K-Means clustering, but the efficiency is low, it is difficult to obtain high recognition accuracy[4]. FCM algorithm using fuzzy theory can overcome the shortcomings. Some scholars have improved the FCM algorithm, which improved the precision of abnormal data recognition of the communication network[5].

In order to improve the communication network identification accuracy, the abnormal recognition method of data mining algorithms based on communication network data. First on the communication network data samples for fuzzy c-means clustering, obtains the degree of membership matrix, and then according to the membership degree matrix selection of abnormal data mining communication network training. The training samples to input the least square support vector machine learning, data mining model based anomaly of communication network, and the

simulation results on the performance of the algorithm was tested. The results show that this method can improve the data mining efficiency and accuracy of the communication network.

The principle of abnormal data recognition in communication network

Communication network security is affected by a variety of factors, and the abnormal data recognition of the communication network is to extract abnormal data using data mining methods. So the network security personnel can make effective prevention according to the recognition results in order to reduce the loss of communication network security problems. The input variable of communication network at i moment was $\{x_{i1}, x_{i2}, \cdots, x_{im}\}$, and the corresponding data type was y_i, which value was 1 or -1, and 1 represented normal, -1 represented abnormal, then the mathematical model of abnormal data recognition in communication network was expressed:

$$\hat{y}_i = f(x_1, x_2, \cdots, x_m) \tag{1}$$

If all the training samples are put input to the algorithm for learning, it is difficult to calculate. T herefore it is necessary to make cluster analysis on the sample data. FCM algorithm is adopted for c lustering analysis in this paper , and the training samples are sent to LSSVM to learn. The structure of abnormal data recognition in communication network based on FCM-LSSVM is shown in Figure 1.

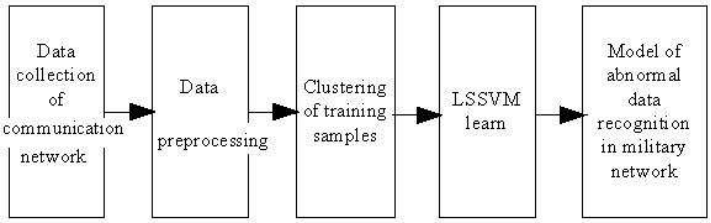

Figure 1 Structure of abnormal data recognition in communication network

The method of abnormal data recognition in communication network based on FCM-LSSVM

A. Least square support vector machine (LSSVM)

The training set of communication network data was supposed as {xi, yi}, so the linear function of optimal classification hyper plane of LSSVM in high dimensional feature space was:

$$f(x) = w^T \varphi(x) + b \tag{2}$$

In which, ω is the weight vector and b is the offset.

According to the structural risk minimization principle, type(2) can be expressed in a constrained optimization problem:

$$\min_{w,b,e} J(w,e) = \frac{1}{2} W^T W + \frac{C}{2} \sum_{i=1}^{n} e_i^2 \quad s.t. \;\; y_i = w^T \varphi(x) + b + e_i, i = 1, 2, \cdots, l \tag{3}$$

Where, C is the penalty parameter and ei is the prediction error.

The constrained optimization problem became a unconstrained optimization problem by introduc ing the Lagrange multiplier, and the Lagrange function was established as:

$$L(w,b,e,\alpha) = J(w,e) - \sum_{i=1}^{l} \alpha_i \left(w^T \varphi(x_i) + b + e_i - y_i \right) \tag{4}$$

In which, α_i is the Lagrange multiplier. According to KKT conditions, we select the radial basis kernel function as kernel function of LSSVM, the recognition decision function of LSSVM abnorm al data recognition in communication network is:

$$f(x) = \operatorname{sgn}\left(\sum_{i=1}^{n} \alpha_i \exp\left(-\frac{\left\| x_i - x_j \right\|^2}{2\sigma^2} \right) + b \right) \tag{5}$$

In which, σ is the width parameters of the radial basis kernel function.

B. The recognizer design of abnormal data

LSSVM is the two meta classifier, and communication network's abnormal data types, must con struct multiple recognizers to do the abnormal data recognition of the communication network, the " one to many" way was constructed multiple classifiers to identify the abnormal data. For example, t he abnormal data in communication networks has a total types of 4, and the abnormal data for +1, t he normal data for -1.

C. Fuzzy c-means clustering (FCM)

Supposing the data set in FCM algorithm is $X=\{x_1,x_2,\cdots,x_n\}$, and n is the number of data sets of X, which each element is a vector p, containing a class c, the class i center is $v_i=\{v_{i1},v_{i2},\cdots,v_{ip}\}$, the elements j in the X membership to the class centers of degree i is u_{ij}, $U=\{u_{ij}\}$, $V=\{v_{ij}\}$:

$$u_{ij}\in[0,1] \qquad \forall i,j,\sum_{i=1}^{c}u_{ij}=1 \qquad \forall j,\ \forall i,0<\sum_{j=1}^{n}u_{ij}<1 \tag{6}$$

The objective function for FCM algorithm is:

$$J(U,V)=\sum_{i=1}^{c}\sum_{j=1}^{n}u_{ij}^{m}\left\|x_j-v_i\right\|^2=\sum_{i=1}^{c}\sum_{j=1}^{n}u_{ij}^{m}d_{ij}^2\to\lim \tag{7}$$

Conditional extreme value of J function can be obtained by the method of Lagrange multipliers. First of all, the J function in the formula (7) under the extreme conditions can be expressed as:

$$J(U,V)=\sum_{i=1}^{c}\sum_{j=1}^{n}u_{ij}^{m}d_{ij}^2+\lambda\left(\sum_{i=1}^{c}u_{ij}^{m}-1\right) \tag{8}$$

In the formula (8), parameter λ is a constant. The two first order partial derivatives of J function is:

$$\frac{\partial J}{\partial u_{ij}}=mu_{ij}^{m-1}+\lambda,\frac{\partial J}{\partial v_{ij}}=-2\sum_{j=1}^{n}u_{ij}^{m}d_{ij} \tag{9}$$

Experiment and Analysis

Simulation experiment data is from the American DOD Lincoln Laboratory DARPA data set, which is composed of the normal data and the different types of abnormal data. And the abnormal behavior are: denial of service (DOS), remote unauthorized access attack (R2L), non authorized to obtain super user privileges attack (U2R), vulnerability detection and scanning attack (PROBE), each data consisting of 41 attributes, 7 of them are symbolic variables, 34 is a continuous variable. Because the DARPA data set is large, only 10% of the data was used in the experiments. The experiments are taken on the Intel Core4 2.8GHz, 2GB memory, simulation platforms are Windows XP and Matlab 2012.

The feature scope of DARPA data set is different, and the LSSVM is based on a sample and a h yper plane distance. A few characteristic has a strong influence on the performance of LSSVM, and the other characteristics have small influence. Therefore we need to eliminate the negative impacts. Comparison of the running time of algorithms, compared with K-Means, FCM and LSSVM, the run ning time of FCM-LSSVM is greatly reduced, and it greatly improves the recognition efficiency of communication network abnormal data. The data recognition results are shown in Figure 2, and it s hows that the method has good data mining and recognition performance in communication applicat ion.

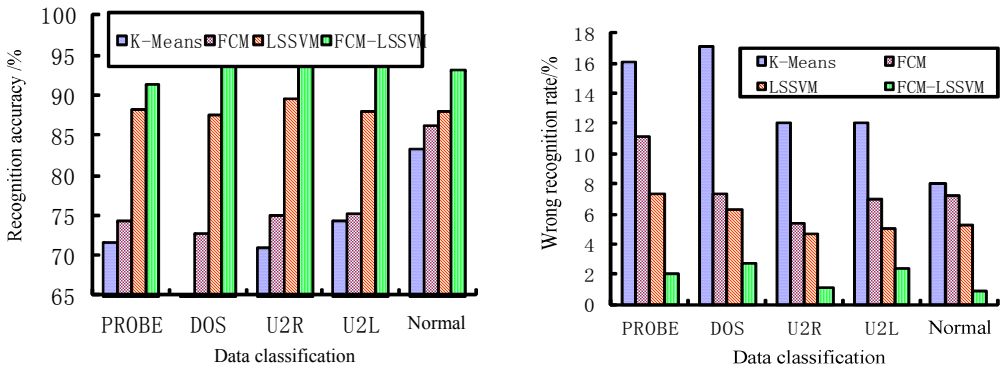

Figure 2 Data recognition results with different algorithms

Conclusions

In view of the abnormal data mining problems in current communication network, FCM-LSSVM mining algorithm was proposed in this paper. In the training sample extraction process, FCM-LSSVM only extracts the samples relatively close to the cluster center, which have representativeness and better performance. Combining with the LSSVM generalization ability, the mining accuracy can be improved very well. The experimental results show that the FCM-LSSVM classification was better than the unsupervised classification algorithm, and the extraction of training samples is more simple and reasonable. Comparing to the unsupervised classification and supervised classification algorithm, FCM-LSSVM need more time to classify, but data mining accuracy of communication network was increased greatly. FCM-LSSVM is suitable for the application of abnormal data mining in communication network, without complex process of training samples from supervised classification algorithm.

Keywords: multi-signal conflict; one-card; optimal design

Abstract. IC card is a product of microelectronics, computer and information technology, with the development requirements of its wide application and digitized, one-card system will inevitably become a trend. The operation mode of one-card System with "one card, one database, one network", can both realize the norms for user management, but also provide important information for managers. Meanwhile, as an important part of digital one-card systems is one of the foundation works of information collection in the digital environment. It has the great significance for management and decision support of users.

Introduction

In the crowded environment, the designed one-card system based on multi-signal model is also being widely used [1]. Campus one-card system is one typical representative, which combines computer technology, network communication technology, automatic control technology and smart card technology. Various decentralized management and service facilities within the same system are fully integrated into computer management system to achieve the highly integration and full functionality of entire intelligence management system [2]. The main design idea is that by building standardized, secure, and scalable campus management system to fulfill informational, intelligent, self- oriented campus management [3]. The basic construction process is to solve the problem of campus electronic money, then according to the standards of educational industry information system construction and regulation of campus card to extend information technology applications and services to all aspects of campus management [4]. "Campus One-Card System" as an important part of digital campus, is one of the basic engineering of digital information collected on campus ,which has great significance for school management and decision support.

Multi-signal optimal design models

Chip and the antenna have no exposed parts, cards at a certain distance (typically 5-10mm) close to the surface of the reader, by passing radio waves to complete read and write operations of data. The technology succeeded in combining radio frequency identification technology and IC card technology together to solve the problem of no power supply in the card and non-contact, which is a major breakthrough in the field of electronic devices

A.operating principle of one-card

Currently, in one-card system, a contactless IC card with the carrier frequency of 13.56MHz generally is used, also known as radio frequency card or proximity card. It consists of inductive antenna and IC chips, packaged in a standard PVC cards. chip and antenna without any exposed parts card at a certain distance (typically 5-10mm) near the surface of the reader, the transmission by radio waves for reading and writing operation of data. It succeeded in radio frequency identification technology and IC card technology together to solve the passive (no power supply card) and avoid contact with this problem, a major breakthrough in the field of electronic devices.

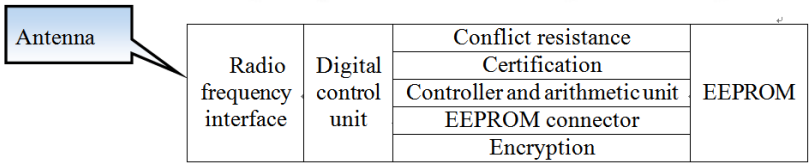

Figure 1 Logical block diagram of Mifare 1 S70 's

The non-contact IC card energy transfer process is as follows (Mifare example): the card itself is a passive member , when writing is operated on the card reader, the reader send a fixed frequency electromagnetic waves to the IC card, the card which has a L / C series resonant circuit , the frequency of it is same to the reader, thus generating an electromagnetic resonance, so that the capacitor has been charged. At the other end of the capacitor has a one-way electronic pump, which is used to transmit the charge in the capacitor to the other capacitor to store. When the charge storage accumulation reaches 2V, this power supply provides the operating voltage for the other circuits to transmit the data in the card or receive the data in reader (rate of 106kbps). Mifare 1 S70 has the logic diagram shown in Figure 1, the internal part mainly consists of the analog, digital section and the storage unit.

Non-contact reader includes two opposite paths flowing signal channel: the upper transmit channel and the lower receiver channel. Firstly, in the transmit channel, the corresponding frequency of carrier signal is generated from the quartz crystal oscillator with stable frequency. The signal will be made amplitude shift keying (ASK) modulation by the planned sending message which has been coded based on Manchester or variant Miller or the NRZ rules in the ASIC segment, and finally after a power output stage amplifier , it can be transmitted by the antenna . In receiving channel, interference and noise is filtered in input signal firstly. The weak response signal of non-contact type IC card is extracted from the high -intensity transmit driven signal, and then be amplified for further ASIC processing.

B.The realization of multi-signal Anti-collision operation

Setting the taken energy of signal transmission in one-card application process can be represented by y_T, the time consuming of this process can be with y_V , then, the following equation can be expressed the energy relationship:

$$y = y_T + y_V \quad (1) \qquad y_T = s_p(R_{Tv} + R_{Tt}H) \quad (2)$$

$$y_V = s_p R_{Vt} + wpR_{Vv} \quad (3)$$

Setting the number of all signals can be represented by p, the number of slots in signal transmission can be represented by H, the number of levels of the binary tree can be represented by N, then the number of time slots can be calculated using the following equation:

$$H = 2^N \quad (4)$$

The probability of a tag response can be calculated using the following equation when signal transmit in the designated channel,:

$$R(K) = \begin{cases} (1+D^N) & (N>0) \\ (H-1)^Q / H^Q & (N=0) \end{cases} \quad (5)$$

In this channel, there is no responding probability of tag can be calculated using the following formula:

$$R(U) = \sum_{m=1} R(m,p,N) R_{QE}(H,m) =$$

$$\begin{cases} \sum_{m=1} R(m,p,N) R_{QE}(H,m) & (N>0) \\ p(H-1)^{Q-m} / H^Q & (N=0) \end{cases} \quad (6)$$

Using the following equation, the probability of signal collision in this time can be calculated:

$$R(E)=1-R(U)-R(K)=1-R(U)-R(K)$$
$$=1-(1-D^N)-\sum_{m=1}R(m,p,N)R_{QE}(H,m) \quad (7)$$

Thereinto, $R_{QE}=H/H(H-m)$. In search process by using binary, the probability of signal collision occurs in specified channel can be calculated by the following equation:

$$Z_{y,N,p}=Z_{N,p}=1-(1-D^N)-$$
$$\sum_{m=1}R(m,p,N)R_{QE}(H,m)\ (N>0) \quad (8)$$

When the number of binary levels $N=0$, $z_{y,p}=1-R_{QE}(H,p)$. Using the following formula can calculate the probability of the N -layer binary occurs in the signal collision of y -th channel:

$$X_{y,N,p}=\begin{cases}1\ (N=0)\\ Z_{N-1,p}\ (N>0)\end{cases} \quad (9)$$

In the process of N -layer binary searching, it can use the following formula to calculate the number of slots:

$$v(p)=(H+1)\sum_{k=0,y=0}X_{y,N,p}$$
$$=(H+1)\left|1-\sum_{N=1}D^N X_{N,p}\right| \quad (10)$$

Assuming the specified tag is responding in the slot time, the collision problem of the nodes of a binary tree in this hierarchy exists in the signal channel, and the collision probability of the signal can be calculated using the following formula:

$$\mu_{y,q,p}=\sum_{m=1}mR(m,p,q)R_{QE}(H,m) \quad (11)$$

According to the above described, the signal can be made anti-collision operation, thereby reducing the probability of collision.

simulation experiment and results analysis

A. Structure of Campus Card System

In an example of a technical secondary school's campus card, the system function module mainly composes by the card system platform and application subsystems (shown in Figure 2) :

Application subsystem divides into logistics group , financial , academic , student office, and so on. in, the dual-use and compatibility of the network on / off is fully considered in the structural design of campus card system.

(1) Networking technology selection.

The fast Ethernet switching networking is used in the backbone network of campus card. it has the advantage of mature technology and low investment costs. Moreover, it can meet application needs of medium-sized network by combining with switching technology. RS485 star topology is used in Subnets, and seamlessly connected with Ethernet via protocol converter to ensure real-time data transmission.

(2) Network communication protocol selection.

In order to ensure openness and compatibility of networks, TCP / IP is selected as the communication protocol of network applications. TCP / IP can support different communication network between different types of operating systems and communication modes, including Ethernet, FDDI, Token Ring, X. 25 packet switch network and Frame Relay networks. RS485 communication protocol is selected in Subnet. The use of RS485 communication protocol can

reduce the cost. It can extend the communication distance of one terminal equipment to 1 200M, far exceeding the limit of 100M of Ethernet equipment.

B. operating mechanism of one-card system

Finally, all transactions occurred in card system will be collected to card data centers with the form of day-to-day. Therefore, the system should ensure the correctness and uniqueness upload of current count. It can neither lose any of transaction, nor upload the transaction repeatedly.

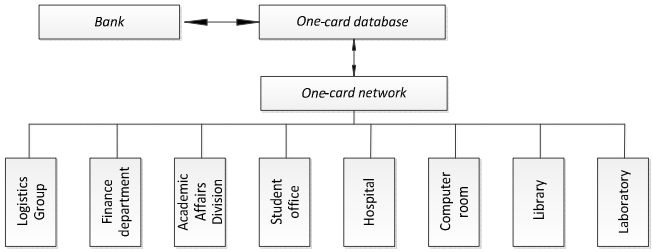

Figure 2 Function modules of one-card system

C device, application access and authentication

The access equipment includes a variety of card machines (eg POS, cash recharge machine, transfer machine, etc.). The access application includes various application systems, third-party integration system (libraries, schools hospitals, finance, etc.). It needs to prevent illegal equipment and illegal applications circulated into the network. All card machines must be authorized to use in the private card network. It has to carry through check-in and check-out and verify the legitimacy. All devices and applications are filed in the application management center. The cardholders system must have black and white lists inspection mechanism.

D.Experimental results and conclusions

According to multi-signals collision algorithm and the general algorithm, the data extracted from the card is for 10 times test generation respectively. As shown in Table 1, compared to the traditional algorithm, the performance of algorithm in this paper is with less time-consuming and high accuracy almost in all the circuits. The effects in some circuits are remarkable.

Table 1

	Time（ms）		accuracy rate（%）	
number of trials	traditional algorithm	algorithm in this paper	traditional algorithm	algorithm in this paper
1	53	32	84	93
2	56	33	86	94
3	54	35	87	95
4	53	32	84	93
5	55	33	86	94
6	54	35	86	93
7	55	33	85	95
8	52	34	85	94
9	54	35	85	95
10	56	34	87	93

Conclusion

Digital goal of building has two levels. Firstly, the goal of digitizing must follow and serve the overall development goals of constructing the high-quality, high-level, international and open-class multi-disciplinary university. Secondly, in the technology, it is to build unified data center, highly resource sharing business application platform, provide personalized information services and build digital management environment.

Testing indicators improved significantly through multi-signal collision optimal design, indicating that the optimal design is successful. If the optimization design can be carried out synchronously between the card system performance and the structural design, the system will be higher optimization levels.

Design and Simulation of Wireless Communication System Channel in Coal Mine Based on OFDM Technology

Ma Ronghua[1,a]

[1]Computer Software and Theoretical Research, ZhengZhou Railway Vocational&Technical College ZhengZhouHeNan 450000, China

[a]50005280@qq.com

Keywords: channel; OFDM; delay spread

Abstract. The OFDM technology is applied in the mobile communication system of underground coal mine, the wireless communication system channel of underground coal mine is researched. The underground channel model is established, and the simulation is taken for testing the performance of system. The simulation results show that the OFDM technology can be applied in the mobile communication system in underground coal mine, and the transmission rate of the system and the ability of anti-interference are improved.

Introduction

In the underground coal mine, the mobile communication is playing an important role in mine scheduling, motor vehicle drivers communication, and the communication with other staff. It is the main means of communications for the mine operators, with the efficient communication system, the mine safety can be ensured. The efficient production can be obtained, and the disaster relief is realized. Electromagnetic wave is a multi-path propagation in the tunnel of coal mine, because of the mine environment is special and complex, the signal occurs delay spread, and the inter symbol interference (ISI) is occurred in the digital transmission system. The performance of digital communication system is affected seriously. Multi carrier orthogonal frequency division multiplexing (OFDM) technology is used to increase the symbol transmission time with parallel transmission, cyclic prefix is used to eliminate the inter symbol interference, and it can effective process the delay caused by multi-path transmission expansion.

Characteristics and model of wireless channel of underground coal mine

A.Characteristics of underground wireless channel

Because the coal production mainly is worked in underground, working environment is poor, the work area is narrow with poor lighting, and the humid and corrosive are serious. Security threats from water, fire, gas, roof accident are great, mobility of staff and equipments is great, and d other special factors are complicated.

(1) Multi-path propagation phenomenon of underground communication

The roadway of coal mine is relatively narrow in China, the length is up to several 10km, and it is distributed in different levels, section size usually reaches to tens of meters, tunnel wall rock and coal seam are rough, there are large number of dust, coal mining support, mechanical and electrical equipment, rail, power lines, and so on, the environment is very special and complex. Electromagnetic wave generates multi-path effect in communication, it affects the transmission quality.

(2) Received signal is time varying signal

In the underground wireless communication, due to antenna distribution in the tunnel, emission efficiency of the antenna is very low. The propagation velocity of electromagnetic wave is great. In addition, because of mine locomotive motion, the relative movement between the radio receiver and transmitter is occurred, there is Doppler effects. This leads to the signal receiving device is a time-varying signal, the amplitude fading is produced, and the signal to noise ratio of communication is low.

(3) Serious interference from underground electrical and mechanical noise

Electricity is the main power of the coal mine production, the main equipments are mine locomotive, excavator, fan relies on electricity to drive. The use of electricity is from the electromagnetic noise and electromagnetic radiation. The noise has become one of the important factors that influence the quality of communication.

B.Wireless channel model of coal mine

Most of coal mine roadway is flat, electromagnetic wave exists two kinds of fading propagation in this tunnel: one is the signal fading caused by the remote transmission for large scale fading, another kind is the signal fading arising from multipath propagation which is called the small scale fading. When frequency of wireless communication device above the cut-off frequency of tunnel, signal fading is decreased with the frequency increasing, it belongs to the large scale fading.

Table 1 Effect on the frequency of straight tunnel decay rate

Frequency(MHz)	40	60	150	470	900	1700
Attenuation (dB/km)	301	217	113	9.8	2	1.6

The system frequency is selected as is 1.8GHz, then the cause of signal attenuation is multi-path propagation. The statistical characteristics of small scale fading are analyzed. Assuming that the input signal into the channel is $s(t)=\mathrm{Re}\left(s_l(t)e^{j2\pi f_c t}\right)$, and the discrete multi-path channel can be expressed as $y(t)=\sum_{n=1}^{L}\alpha_n(t)s\left[t-\tau_n(t)\right]$.

Where, $s_l(t)$ is the equivalent low pass signal, f_c is carrier frequency, $\alpha_n(t)$ is the path delay with n paths, and $\tau_n(t)$ is the time delay of n paths, L is the number of paths. After low-pass equivalent, the

The carrier frequency, attenuation is the path, is a path delay, path number. After low-pass equivalent, $s(t)$ can be expressed as

$$s(t)=\mathrm{Re}\left[\tilde{s}(t)e^{j2\pi f_c t}\right] \tag{1}$$

Then, $y(t)=\mathrm{Re}\left\{\left(\sum_{n=1}^{L}\alpha_n(t)e^{-j2\pi f_c\tau_n(t)}\tilde{s}(t-\tau_n(t))\right)\right\}e^{j2\pi f_c t}$

The complex envelope of output signal is:

$$\tilde{y}(t)=\sum_{n=1}^{L}\alpha_n(t)e^{-j2\pi f_c(t)\tau_n(t)}\tilde{s}(t-\tau_n(t))=\sum_{n=1}^{L}\tilde{\alpha}_n(t)\tilde{s}(t-\tau_n(t)) \tag{2}$$

As formula (2) shows, the following complex time-varying low-pass equivalent impulse response $\tilde{c}(\tau;t)$ is used to describe multipath channel as:

$$\tilde{c}(\tau;t)=\sum_{n=1}^{L}\tilde{\alpha}_n(t)\delta(t-\tau_n(t)) \tag{3}$$

Where, $\tilde{c}(\tau;t)$ represents the added $t-\tau$ pulse channels in the t time response.

Because each path of discrete multipath channel can be regarded as the result of joint action of many scattering components, therefore, each tap of paths can be regarded as a complex Gauss random variables.

According to the channel model proposed by Bello, assume that the channel impulse response is wide sense stationary (WSS) random process, it meets:

$$R_{\tilde{c}\tilde{c}}(\tau_1,\tau_2,\alpha)=E\left\{\tilde{c}^*(\tau_1,t)\tilde{c}(\tau_2,t+\alpha)\right\} \tag{4}$$

Assumed the phase values are not correlated in different paths and different amplitudes, then:

$$R_{\tilde{c}\tilde{c}}(\tau_1,\tau_2,\alpha)=R_{\tilde{c}\tilde{c}}(\tau_1,\alpha)\delta(\tau_1-\tau_2) \tag{5}$$

The autocorrelation function of WSSUS channel can be expressed as:

$$R_{\tilde{c}\tilde{c}}(\tau,\alpha)=E\left\{\tilde{c}^*(\tau,t)\tilde{c}(\tau,t+\alpha)\right\} \tag{6}$$

The scattering function of the multipath channel is defined as:

$$S(\tau,\lambda)=F\left\{\left(\underset{\sim}{R}_{cc}(\tau,\alpha)\right)\right\}=\int_{-\infty}^{\infty}\underset{\sim}{R}_{cc}(\tau,\alpha)\exp(-j2\pi\lambda\alpha)\,d\alpha \tag{7}$$

Assume that the bandwidth of input signal $s(t)$ is W, according to the sampling theorem, the equivalent low pass signal can be expressed as:

$$\tilde{s}(t-\tau)=\sum_{n=-\infty}^{\infty}\tilde{s}(t-nT)\frac{\sin\left(2\pi B(\tau-nT)\right)}{2\pi B(\tau-nT)} \tag{8}$$

Where, $B=W/2$ is the equivalent baseband signal bandwidth, the sampling interval is $T=\frac{1}{2B}=\frac{1}{W}$, the output equivalent low pass signal is:

he equivalent baseband signal bandwidth, sampling interval. The equivalent low-pass signal output is:

$$\tilde{y}(t)=\int_{-\infty}^{\infty}\tilde{c}(\tau;t)\left\{\sum_{n=-\infty}^{\infty}\tilde{s}(t-nT)\frac{\sin\left(2\pi B(\tau-nT)\right)}{2\pi B(\tau-nT)}\right\}d\tau \tag{9}$$

Assumed the length of the channel impulse response is NT, if n<0 or n>N, the value of $\tilde{g}_n(t)$ is 0 approximately, the relation between input and output as above can be approximated as:

$$\tilde{g}_n(t)\approx T\cdot\tilde{c}(nT;t) \tag{11}$$

$$\tilde{y}(t)=\sum_{n=0}^{N}\tilde{s}(t-nT)\tilde{g}_n(t)\approx T\sum_{n=0}^{N}\tilde{s}(t-nT)\tilde{c}(nT;t) \tag{12}$$

The above model is firstly proposed by Kailath, called TDL channel mode, the structure is shown in Fgure 1.

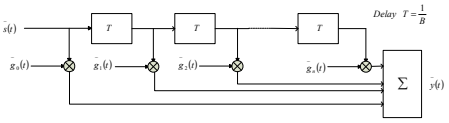

Figure 1 Tapped delay line (TDL) channel model

Communication system construction of underground coal mine and performance simulation

The OFDM physical layer parameters selection is very important to the performance of the system. According to the radio waves as above, the propagation channel model in the underground is calculated as 1.8GHz, the RMS delay spread of model 1 is $\tau_{rms}=46ns$, in the model 2, the RMS delay spread $\tau_{rms}\approx 62n$, the delay spread for indoor radio propagation is $60.6ns$, according to the IEEE802.11a standards, the OFDM physical layer parameters are expressed as follows: working frequency is 1800MHz, the bandwidth of the system is 20MHz, the number of subcarriers is 64, sub carrier spacing is 0.3215MHz(20MHz/64), the effective symbol period is $3.2\mu s(1/0.3125MHz)$, protection interval is 0.8 μs, modulation is 4QAM, the maximum transmission rate is $26Mbits/s(2\times 1/4\mu s\times 52)$. In order to facilitate the simulation, equivalent baseband model of OFDM system. In figure 2, the binary system simulation results is shown, the channel estimation uses LS estimation, the error rate results are calculated, it shows that the new method has better performance.

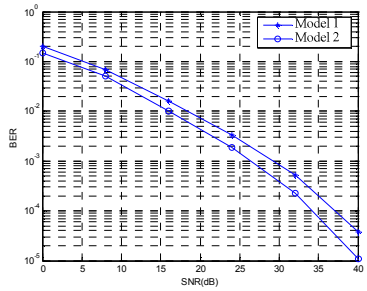

Figure2. Comparison of bit error rate of OFDM system in underground coal mine communication

Keywords: Astronomical image, cross-correlation, medical image analysis

Abstract. Image registration is widely used in the areas of image fusion, target tracking, remote sensing data analysis, medical image analysis such as organization pathological changes, under the constantly exploring to the image registration technology. In this paper astronomical image matching based on the cross-correlation algorithm is proposed and we focuses on adopting the registration form using the cross-correlation method after segmenting the astronomical images. The method can effectively solve the difficulties of the overall matching, represent the salient regions of features and implement local matching.

1. Introduction

With the rapid development of science and technology, people desire to have a better knowledge of undiscovered areas and devote to the aerospace industry with full enthusiasm, so that the industry becomes a hot research topic. Aimed to obtain high-quality astronomical images, a large number of images are shot in a small time interval and registered. Astronomical images are mostly gray-scale images. With regard to the same image, multiple independent regions of interest co-exist, and the relative positions of interest region shot in a short time are so relatively fixed that large rigid movements are not easy to be generated in a short time. But when flipping images of the same group continuously, it is to find: a considerable problem of the local rigid movement exists in the images, that is to say, regions with rich information head for different directions at the same time. It makes overall matching for images difficult.

In the field of image processing, image segmentation as a key technology for image processing becomes increasingly important, and the segmentation results directly affect the quality of subsequent operations such as feature extraction and target recognition. The aim of image segmentation is to divide an image into several disjoint and a valuable collection of connected subregions in computer vision. The literatures [1][2] carry on a summary to image segmentation technology. Two segmentation methods adopted most frequently have: region-based segmentation and edge-based segmentation. The idea of region-based segmentation is to guarantee as far as possible that feature similarity within regions is greater than interregional that. The commonly used methods have: threshold method, region growing method and splitting and merging method. Generally, edge shows mutation or discontinuity of image features, and edge-based segmentation is to detect these features and form the boundary. The methods used mostly have: Robert operator, Sobel operator, Prewitt operator, Canny operator, Laplasse operator, differential operator [3] and boundary tracking method [4]. In addition, some new algorithms are proposed by combining image segmentation with some specific theories and methods. Regarding the possible solutions to the problem domain as the chromosome groups, the genetic algorithm [5] which has a global searching ability and can avoid the extremal solutions to a certain extent, is generated. In 1988, Osher and Sethia [6] firstly proposed a numerical method which can solve the problem of curve evolution effectively. Subsequently, relevant extensions and a summary of this algorithm were made by Oshe et al [7][8] again. Due to its stability and suitability for any dimensional space, this method is widely adopted at present.

The concept of mutual information from information theory, a measure of useful information, is used to measure the degree of correlation between two random variables. Woods et al [9] proposed and modified an automated method that allowed for cross-modality registration of MRI and PET brain images obtained from a single subject. Maes et al [10] investigated the performance

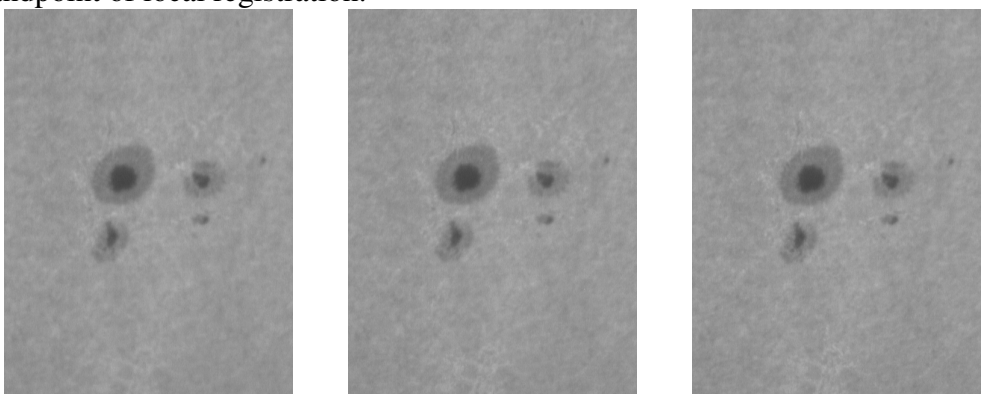
of various optimization methods and multiresolution strategies for maximization of mutual information, and pointed out that the multiresolution method can effectively overcome the local extremum. Maintz et al [11] proposed to use a global joint histogram based on optimized mutual information combined with a local registration measure to enable local elastic registration. Pluim et al [12] proposed to include spatial information by combining mutual information with a term based on the image gradient of the images to be registered, and made a clear improvement in robustness.

This paper focuses on adopting the registration form using the cross-correlation method after segmenting the astronomical images. Firstly, regions of interest in the images are extracted and segmented according to the principle of image segmentation. Then, the displacements are calculated by using the cross-correlation algorithm. Finally, the registered images can be obtained by performing the fusion of the obtained regions. The method can effectively solve the difficulties of the overall matching, represent the salient regions of features and implement local matching.

2. Extraction of region of interest

2.1 Experimental images

Figure 1 illustrates the experimental images of this paper, which is extracted randomly from 100 serial images shot continuously at the given points by the same sensor. Comparing three images with each other, tiny changes among them are difficult to be observed with human eyes. However, it is to find that regions of interest head for a tiny distance towards different directions if flipping the images continuously. In view of this, defects of the overall matching are considered to be eliminated from the standpoint of local registration.



(1) A1 (2) A2 (3) A3

Figure 1 Experimental images (480*640 pixels)

2.2 Binarization processing

In this paper, the Otsu method7-8 is used to determine a binarization threshold value for image segmentation [13-16]. The Otsu method aims at obtaining the optimal threshold by traversing all the gray levels (i=1, 2,…, l) of an experimental image $f(x,y)$. By using the threshold value t, experimental images are divided into two target areas, C_0, C_1 respectively. P_i is the probability after normalizing the histogram. The optimal threshold is denoted as t*.

$$t^* = \arg\max_{i \in l} \delta^2{}_B$$

Where $\delta^2{}_B = \omega_0(\mu_0 - \mu_T)^2 + \omega_1(\mu_1 - \mu_T)^2$, and $\omega_0 = \sum_{i=0}^{t} P_i$, $\omega_1 = 1 - \omega_0$, $\mu_T = \sum_{i=0}^{l-1} iP_i$,

$\mu_0 = \sum_{i=0}^{t} iP_i$, $\mu_1 = \sum_{i=t}^{l-1} iP_i$.

Thus, after binarizing the experimental image $f(x,y)$, $g(x,y)$ is:

$$g(x,y) = \begin{cases} 0, f(x,y) < t^* \\ 255, f(x,y) \geq t^* \end{cases}$$

Figure 2 shows an image of the experimental effect after binarizing A1 of Figure 1 by using the Otsu method.

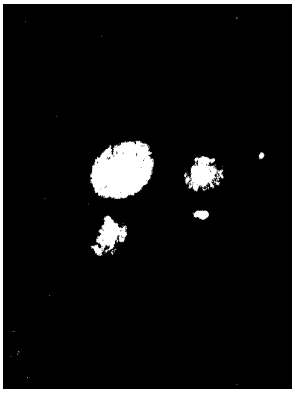


Figure 2

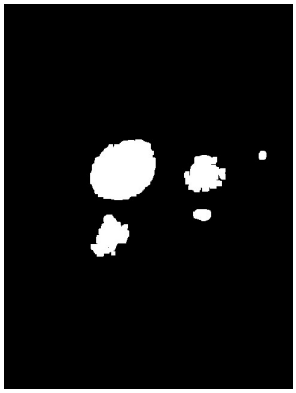

Figure 3

2.3 Morphological processing

Although the locations of five regions of interest can be distinguished clearly in Figure 2, their shapes are very irregular and a great number of holes exist, which makes subsequent cross-correlation registration inconvenient. In this paper, the morphology operations of dilation and erosion are used for image processing.

Pixels are introduced into object edges of images through the dilation operation. During this process, the value of output pixel is the maximum of all input pixels. A is dilated by structural element B, namely $A \oplus B$. Object edges of images are removed through the erosion operation. In contrast to the dilation operation, the value of output pixel is the minimum of all input pixels. A is eroded by B, namely $A \otimes B$.

There are three kinds of common operations by the combination of dilation and erosion operation in morphology, one of which is closed operation that is capable of filling effectively holes, linking notches and smoothing boundaries. The closed operation is named as: $A \bullet B$. And its principle is the result of A after being dilated and eroded by B. Therefore, $A \bullet B = (A \oplus B) \otimes B$. Figure 3 is an image of experimental effect of Figure 2.

3. Normalization of spatial segmentation

This paper focuses on using the method of boundary segmentation. However, when using the method, regions of interest is very irregular, which makes subsequent cross-correlation registration inconvenient. On this basis, we consider intercepting rectangular with the smallest area where regions of interest are included. On one hand, the operation makes cross-correlation registration of irregular images more convenient. On the other hand, registration time reduces when choosing the smallest area.

The normalized algorithm for spatial segmentation proceeds as follows:

(1) Find out the points whose value is 1 in Figure 3. If the points exist, record them. Otherwise, terminate the operation.

(2) Track and search in eight-connectivity and mark the path by choosing the right value. When the round points of tracking target's coordinate are all marked or their values are 0, stop tracking.

(3) Obtain the minimum and maximum of x-axis and y-axis directions in the marked area. When implementing the interception storage of the corresponding rectangular in A (1) of Figure 1, intercepting and st 1A (1) to the corresponding rectangular interception storage, matrix scope is to be appropriately extended around. Some black edges are generated in cross-correlation registration. And the integrity of region of interest can be guaranteed by extended rectangular.

(4) Go to step (1), continue to carry out inspection.

Figure 4 shows the effect images of normalized spatial segmentation for A (1) of Figure 1 according to the above algorithm.

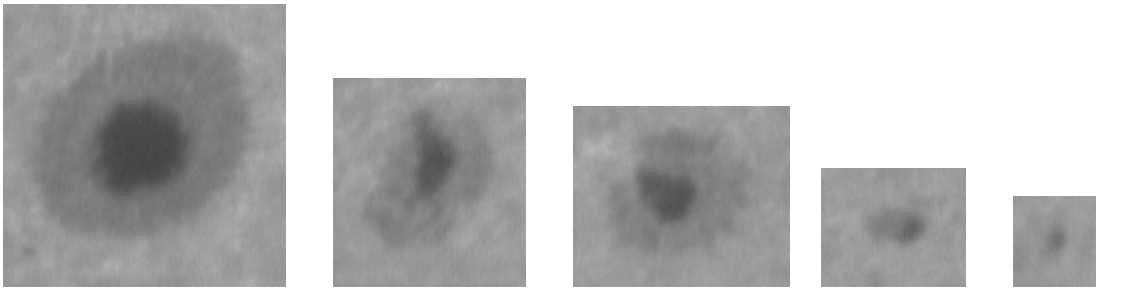

Figure 4 The effect images of normalized spatial segmentation

4. Cross-correlation registration and result analysis

4.1. Cross-correlation registration

In information theory [18], entropy, a measure of information, is usually used to represent the correlation degree between two random variables. Thus, the entropy of an image is a representation of random of the probability distribution to the image. Edge entropies and the joint entropies of images A and B are expressed as:

$$H(A) = -\sum_{a,b} p_A(a) \log p_A(a), \quad a \in A;$$

$$H(B) = -\sum_{a,b} p_B(b) \log p_B(B), \quad b \in B;$$

$$H(A,B) = -\sum_{a,b} p_{A,B}(a,b) \log p_{AB}(a,b), a \in A, b \in B;$$

Where $p_A(a)$ and $p_B(b)$ represent the probability distribution of image A and B, respectively, $p_{A,B}(a,b)$ represent the joint distribution of image A and B.

Accordingly, mutual information can be defined as:

$I(A;B) = H(A) + H(B) - H(A,B)$;

According to the Dobrushin formula, the formula of mutual information can be converted to a definition based on the probability distribution:

$$I(A,B) = \sum_{a,b} p_{AB}(a,b) \log \frac{p_{AB}(a,b)}{p_A(a) p_B(b)}, \quad a \in A, b \in B;$$

Cross-correlation algorithm for matching[19-22] is mutual information-based algorithm. It aims to find a transformation by which the largest amount of mutual information can be obtained when registration between the transformed image and another one are implemented. Figure 5 and 6 show the transform displacements based on *x* axis and *y* axis in the process of the cross-correlation registration for 100 images. Observing Figure 5 and 6, it is to find that: the trend curve of displacement of the local registration doesn't depend on the trend curve of the overall matching, a big deviation exists in movement distances, the deviation of directions even exists for some images. Obviously, the precision of the overall matching is lower than that of local matching when using the same method for registration. Figure 7 shows the effect image of the overall cross-correlation registration for A (1) of Figure 1. Figure 8 illustrates the images of local registration of each part after its spatial segmentation .

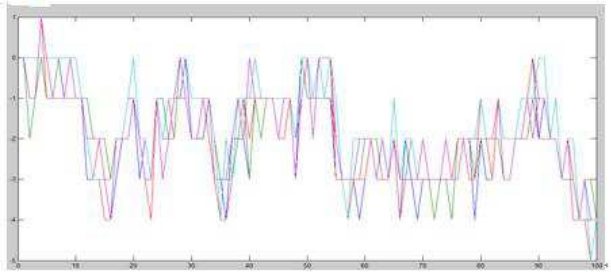

Figure 5 The displacement of *x*-axis direction

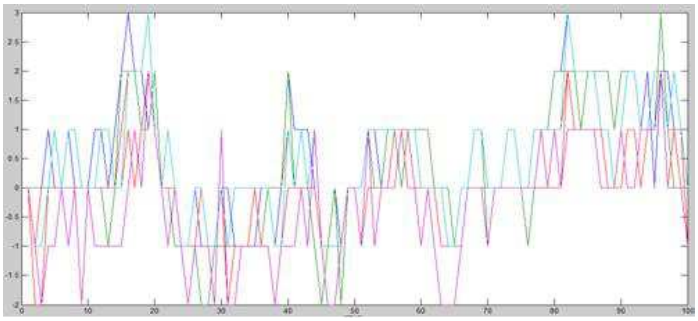

Figure 6 The displacement of *y*-axis direction

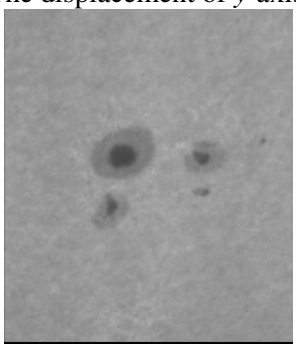

Figure 7 The effect image of the overall matching

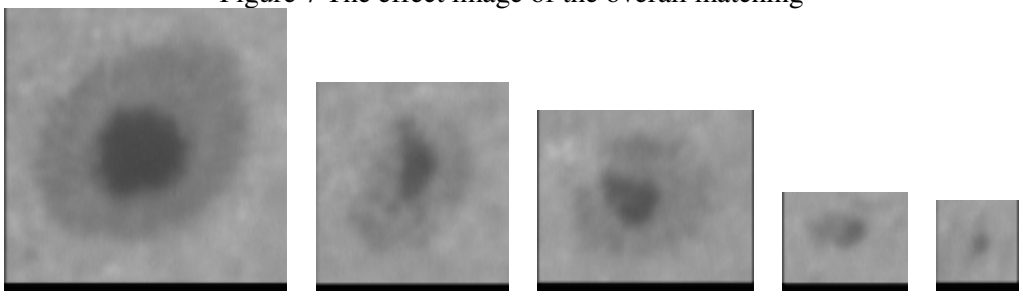

Figure 8 The local cross-correlation registration

4.2 Full-reference image quality assessment

Taking A1 as the standard image, the results in table 1 can be obtained. It can be seen from Table 1 that: the effect of peak signal-to-noise ratio, fuzzy coefficient and quality index of local registration is generally better than that of the overall registration.

Table 1 Results of full-reference image quality assessment

	Peak signal-to-noise ratio (PSNR)	Fuzzy coefficient	quality index
The overall registration	35.1575	0.6377	0.2068
The registration of Part a	38.4992	1.5424	0.6685
The registration of Part b	37.6040	1.5605	0.7760
The registration of Part c	39.2306	1.4929	0.7672
The registration of Part d	37.7845	1.4725	0.8693
The registration of Part e	39.0084	1.2685	0.9047

4.3 No-reference image quality assessment

Due to the inconveniences for selecting full-reference standard image, lots of experiments on quality assessment are performed according to the relevant methods of no-reference images in this paper.

Table 2 Results of no-reference image quality assessment

	Variance	Mean gradient	Fuzzy entropy	Information entropy
The overall registration	226.0073	1.3817	0.3074	4.7918
The registration of Part a	1087.1	2.9801	0.4963	6.1886
The registration of Part b	1001	3.1318	0.3010	5.9087
The registration of Part c	1303.6	4.7608	0.4911	6.1115
The registration of Part d	1975.1	6.7954	0.2488	5.6642
The registration of Part e	2643.7	10.865	0.1941	5.3816

5. Conclusion

Image registration is a hot topic in recent years, and various kinds of algorithms spring up constantly. In this paper astronomical image matching based on the cross-correlation algorithm is proposed and we focuses on adopting the registration form using the cross-correlation method after segmenting the astronomical images. The method can effectively solve the difficulties of the overall matching, represent the salient regions of features and implement local matching.

Although astronomical image matching based on the cross-correlation algorithm has strong flexibility, it has itself advantages, disadvantages and applicable scope. Therefore, besides the innovation, researchers should consider the integration of existing algorithms. The applicable scope of the algorithms can be expanded by collecting the advantages of existing algorithms. In addition, efficiency and robustness of registration need to be focused besides pursuit high quality registration. Some replacement through the registration process can be appropriately used to increase efficiency and enhance simultaneity of registration.

Keywords: VFD Filter; Dynamic Simulation; TT&C signal; High Dynamic

Abstract. A processing method based on VFD Filter is proposed in this paper for implementing the high dynamic simulation of TT&C signal. The method adopts the store-delay way which could implement integer delay for static data and adopts the VFD filter to implement high accuracy fractional delay for the integer delay signal. The simulation and analysis results show that the proposed method not only can accurately and commendably implement high dynamic simulation for TT&C signal, but also suits for different form signal. It provides a good way for dynamic simulation in the compatible test of TT&C equipment.

Introduction

Before the application of new type spacecraft or TT&C(telemetry track and command) equipment, the dynamic compatible test is necessary. Besides, the dynamic performance is an important norm in the test. One traditional test method is based on the flight experiment, however, the speed of airplane is always lower than the speed of missile or spacecraft, which makes the high dynamic performance of new equipment could not be tested. Another traditional test method is based on the dynamic signal simulation through the hardware platform, but this method can only realize integer delay dynamic simulation, which leads to the low precision.

In the application of dynamic compatible test, it is necessary to realize dynamic simulation of TT&C signal which based on the static digital data, frequency up-converter, down-converter and storage device. For this application, a dynamic simulation method for TT&C siganl based on VFD filter is proposed. Some numerical simulations are made to verify the proposed method could be used in the dynamic simulation of differrent form TT&C signal with high accurcy.

Design of dynamic simulation scheme

In the ideal case, the receipt signal $S_r(t)$ can be described by original signal $S_s(t)$ and delay τ as

$$S_r(t) = kS_s(t-\tau) \tag{1}$$

where k is the amplitude fading. It is obvious that the dymaic simulation conlude power and delay simulation by Eq.1. The power of singal is mainly depend on electromagnetic wave propagation distance and channel characteristics, which can be simulated easily by power attenuator. Therefore, the dynamic delay simulation is mainly researched in this paper.

Generally speaking, the signal would has group delay when it passes through the filter, and the group delay of digital filter is linear and controllable in the pass band. Therefore, the signal delay simulation could be realized by controlling the group delay of digital filter. If one want to realize the dynamic simulation of TT&C signal, the problem of fractional and continuous variable delay are necessary to be solved.

In order to solve the problem mentioned above, C.W.Farrow had put forward VFD(Variable Fractional Delay)filter[1], whose frequency response is related to delay. However, the filter coefficient is not related to delay, and the coefficient need be caculated and stored only one time in practice. All this advantages lead the filter was widely used in various signal processing applications, such as sampling rate conversion, time delay estimation and timing adjustment in digital receivers etc.[2-3].

Consider the characteristic of VFD filter, designing the scheme of dynamic simulation, which is shown in Fig. 1.

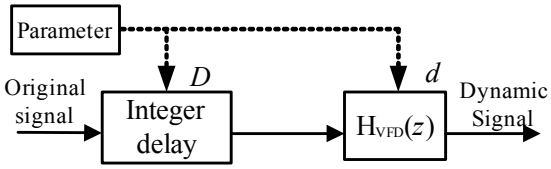

Fig.1. Dynamic simulation scheme based on VFD filter

The integer delay D and fractional delay d are given by parameter calculation module, where D is a positive real integer number and d is a fractional number. If the sampling interval is T_s, we can obtain

$$D = \left\lfloor \frac{\tau}{T_S} \right\rfloor \tag{2}$$

$$d = \tau - D, \quad 0 \le d < 1 \tag{3}$$

The integer delay module implements integer times of sampling interval delay for original siganl according to the parameter D. Besides, the VFD filter implements the fractional times of sampling interval delay for the integer delay signal according to the parameter d. Because of the integer delay is easy to be implemented, this paper is mainly introduces how to use VFD filter to realize accurate fractional delay.

According to the design method of VFD filter which is proposed by Deng T. B. in the Ref. [4]. The filter order N=65, the branch number M=8 and the weighting function $W(\omega, p)$ is assumed to be separable as

$$W(\omega, p) = W_1(\omega) * W_2(p) \tag{4}$$

where

$$W_1(\omega) = \begin{cases} 0.64 & \omega \in [0, 0.55\pi) \\ 4.9 & \omega \in [0.55\pi, 0.85\pi) \\ 37 & \omega \in [0.85\pi, 0.8996\pi) \\ 0 & \omega \in [0.8996\pi, \pi) \end{cases} \tag{5}$$

$$W_2(p) = \begin{cases} 53 & p \in [0, 0.1) \\ 0.2 & p \in [0.1, 0.9) \\ 8 & p \in [0.9, 1) \end{cases} \tag{6}$$

Fig.2 and Fig.3 depict the magnitude response of ideal VFD filter and the simulated VFD filter, respectively.

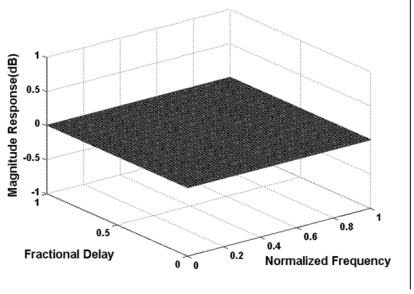

Fig.2. Magnitude response of ideal VFD filter

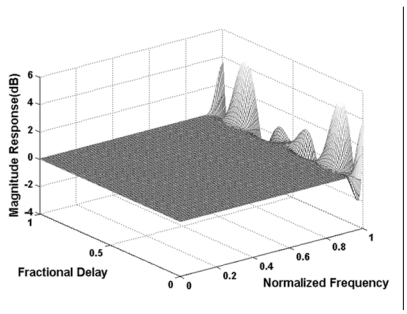

Fig.3. Magnitude response of simulated VFD filter

The results of Fig.2 indicate that the magnitude response of ideal VFD filter is fixed value in the whole frequency range, and no changes with the delay. In fact, it is impossible to achieve the ideal response in whole band, just as shown in Fig.3. Fig.4 depicts the absolute errors of the variable frequncy response that defined in Ref.[4] and Fig.5 illustrates the variable fractional delay response in the range $\omega \in [0, 0.9\pi]$ and $p \in [0,1)$. The results show that the absolute errors are less than -80dB, and the varible fractional delay response of the designed VFD filter is considerably flat in the pass band.

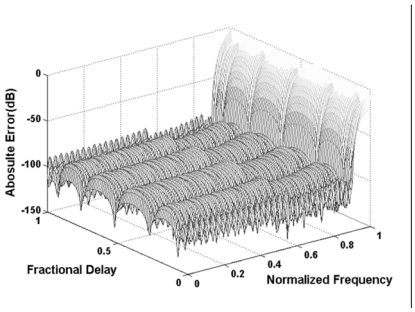

Fig.4. Absolute error of variable frequncy response

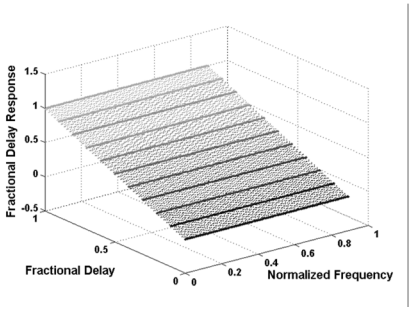

Fig.5. Variable fractional-delay response in passband

If combined with the use of the VFD filter and integer delay, it would be able to solve the problem of fractional and continuous variable delay and realize the dynamic simulation of TT&C signal.

Simulation and analysis

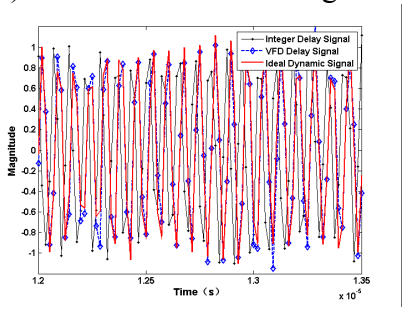
1) Fixed Doppler dynamic simulation

To verify the dynamic signal simulation scheme is correct and effective，the dynamic simulation of standard TT&C signal and PCM_FM signal are simulated. The simulation parameters are displayed in Table 1.

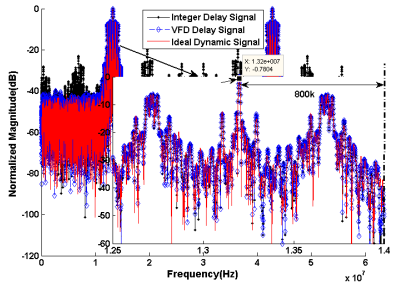
Table1 Simulation Parameters

Form of signal	Original signal parameters	Dynamic parameters	VFD filter parameters
Standard TT&C	Telemetry code rate =64kbps, Telemetry subcarrier frequency=512kHz High side tone frequency=100kHz Low side tone frequency=20kHz	Sampling frequency=56MHz Intermediate Frequency=70MHz Doppler=-800kHz SNR=20dB	Filter order=65 Branch number=8
PCM_FM	Code rate=2Mbps		

The simulation results show that integer delay signal which realized by the method of Ref.[5], the VFD filter delay signal and the ideal dynamic signal. The center frequency of the original signal(14MHz) is also marked in the figures.

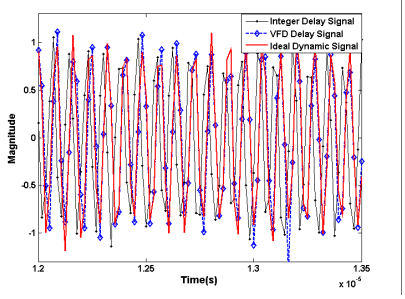


(a) Simulation results in time domain

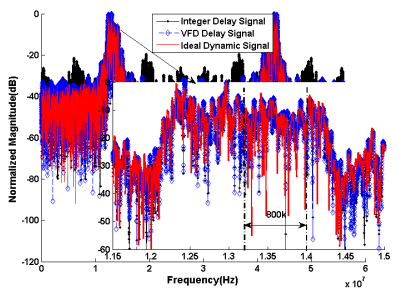


(b) Simulation results in frequncy domain

Fig.6. Fixed Doppler dynamic simulation of TT&C signal



(a) Simulation results in time domain



(b) Simulation results in frequncy domain

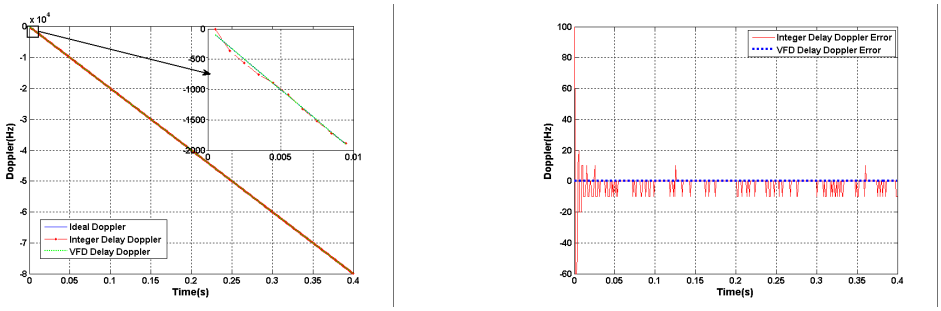
Fig.7. Fixed Doppler dynamic simulation of PCM_FM signal

As we can see from Fig.6 and Fig.7, there is a big error between integer delay signal and the ideal dynamic signal, but almost no error between VFD filter delay signal and the ideal dynamic signal. Moreover, the Doppler frequncy is in conformity with the preset information. Comparison shows that the dynamic simulation effect of the proposed scheme is obviously superior to the integer delay.

2) Varied Doppler dynamic simulation

For a comprehensive study of the dynamic simulation scheme, varied Doppler dynamic simulation of standard TT&C signal was used to verify the proposed scheme. The parameters are same as last simulation except the Doppler changed linearly with the first-order derivative is -200kHz/s.

Through the FFT(Fast Fourier Transformation) operation, we can achieve the Doppler frequency of dynamic signals, which were compared with the ideal Doppler, and the Fig.8 shows the comparison.



(a) Comparison of Doppler (b) Comparison of Doppler error

Fig.8. Varied Doppler dynamic simulation

As shown in Fig.8.(a), there is obviously difference between the integer delay signal's Doppler and the ideal Doppler, but almost no difference between VFD filter delay signal's Doppler and the ideal Doppler. By comparing the Doppler error as shown in Fig.8.(b), we can find that the Doppler simulation error of propose scheme is less than 10Hz and rather less than the error of integer delay.

In summary, all the results indicate that the proposed scheme could be used for dynamic simulation of TT&C singal and the performance of proposed scheme is superior to the traditional integer delay method.

Conclusion

A new scheme combinated with traditional integer delay and VFD filter has been deeply researched for dynamic simulation of TT&C signal in this paper. The simulation results show that the proposed scheme not only can realize high dynamic simulation with high precision, but also could be used in different form TT&C signal. Compared with the traditional demodulation dynamic simulation mode, it has better adaptability and provides an effective solution for the dynamic comptible test of new type spacecraft or TT&C equipment.

Abstract. To deal with the image contrast and color fidelity details problem in the traditional Center around the Retinex image enhancement algorithms, Enhancement Algorithm of Color Fog Image Based on the Adaptive Scale and Multi-parameter correction is proposed. First, the saturation component of the HSI color space is applied to the nonlinear correction. Then according to the brightness of the image pixel values, it can calculates the scale of the Gaussian kernel, and then proceeds to do the multi-parameter correction for the estimates of the reflection component, obtains the multi-scale image by the weighted average. At last, the obtained image is used to adjust the display correction, image sharpening and smoothing, and being superimposed reflection components, achieving the image enhancement. Through the subjective observation and objective evaluation, this algorithm is better than the traditional center around Retinex algorithm in treatment effect, and also saves a large amount of processing time.

Introduction

With misty weather conditions, the outdoor surveillance cameras and equipment with lots of interference [1], namely the contrast and color of recorded images are change and degradation; many features of image become blurred due to being covered with. Therefore, the fog image enhancement is more extra attention. Right now, the common fog image processing methods are mainly bilateral filtering, wavelet transform and Retinex algorithm. Bilateral filtering method can be widely noted due to maintaining the edge characteristic of image, but its treatment only has a significant effect on mist and has greater limitations. Wavelet transform have the characteristics of multi-resolution and the ability to the local signal in time-domain and frequency-domain, in which has been widely used in the image enhancement, but because of its two-dimensional image processing with isotropic, it means that it has limitation when representing the current characteristics and boundaries [2]. Retinex algorithm [3,4,5] is a new idea in image processing development, which is based on color constancy. The full name is the retina double cortex theory that the human eye perceiving an object depends on the color of light reflecting from the surface characteristics of the object and is irrelevant to the incident light. More common are the single-scale Retinex (SSR), multi-scale Retinex (MSR) and multi-scale Retinex with color restoration (MSRCR) algorithms. The MSRCR algorithm is better in these algorithms because of using color restoration, but not maintaining a constant tone, there is still a small color distortion.

In view of the above processing method, Enhancement Algorithm of Color Fog Image Based on the Adaptive Scale and Multi-parameter correction is proposed, which is depend on the nature of the hue, saturation and brightness from the perspective of machine vision in the HSI color space.

The MSRCR algorithm

According to the Retinex theory [6], the color of object is determined by the light reflection ability objects on long wave, medium wave and short wave, rather than by the reflection intensity, which is not affected by non-uniform illumination and is a consistency. The human eye perceiving the brightness depends on the ambient light and the irradiation light of surface reflection, its mathematical expression is:

$$I(x,y) = R(x,y) \times S(x,y) \ . \tag{1}$$

Taking the logarithm on both sides of equation (1), it is given such that:

$$\log I(x,y) = \log R(x,y) + \log S(x,y) \ . \tag{2}$$

where $I(x,y)$ is the image from observing or the camera receiving, $R(x,y)$ is the reflected component of the target object, $S(x,y)$ expresses the incident component of the ambient light.

Then using Gaussian filter to estimate the incidence of component $S(x,y)$ of the image, which is given such that:

$$R(x,y)^{'} = \log I(x,y) - \log[F(x,y) * S(x,y)] \ . \tag{3}$$

where $R(x,y)^{'}$ is the logarithmic of $R(x,y)$, and * denotes convolution, $F(x,y)$ expresses the surround function , here uses Gaussian function, which is defined as: $F(x,y) = K \times \exp(-\frac{x^2+y^2}{\sigma^2})$. σ represents the standard deviation, which is also the scale constant of Gaussian surround function.

According to the surround function, size of scale σ depends on the scope of the convolution kernel. the smaller a scale is, the greater the dynamic range compression is , the local details of the image is more prominent; the larger a scale is, the better the overall image is, the color is more natural and is close to the original color, but its local details is not clear [7]. K is a normalization factor and is now given by: $\iint F(x,y)dxdy = 1$. Single scale is difficult to achieve a large dynamic range compression and better color constancy at the same time. Therefore, it needs to adopt the MSR algorithm, which takes a plurality of single-scale to weight the processing results. The formula is given by:

$$R_{MSR}(x,y)^{'} = \sum_{i=1}^{n} \lambda_i \{\log I(x,y) - \log[F(x,y) * S(x,y)]\} \ . \tag{4}$$

Where n is a number of scales, the value is generally 3; λ_i represents a weight, and meets the equation, $\sum_{i=1}^{n} \lambda_i = 1$, the weight value is 1/3 under normal circumstances.

The multi-scale Retinex with color restitution is based on the results of color from consideration such that introduces a color restitution factor. Mathematically,

$$R_{MSRCR}(x,y)^{'} = \mathrm{C}_i(x,y) \times R_{MSR}(x,y)^{'} \ . \tag{5}$$

where $\mathrm{C}_i(x,y)$ is the color restitution factor , $\mathrm{C}_i(x,y) = \Gamma[\mathrm{I}_i(\mathrm{x,y})] = \Gamma[\frac{\mathrm{I}_i(\mathrm{x,y})}{\sum_{j=1}^{n} \mathrm{I}_j(\mathrm{x,y})}]$, and is used to adjust the proportion of three-channel color; $\Gamma[\mathrm{I}_i(\mathrm{x,y})]$ represents the i channel of the color mapping function, n value is 1,2,3.

Enhancement Algorithm of Color Fog Image Based on the Adaptive Scale and Multi-parameter

When traditional multi-scale Retinex algorithm processes a strong contrast edge region, it will appear the halo phenomenon. The scales are in a fixed number, it isn't free to determine the threshold value according to the features of fog image. After processing, there will be excessive contrast

enhancement. Given above situation, this paper studies the relationship between the image pixels and the scale in the MSR algorithm, and proposes the algorithm. The specific steps are as follows.

Original image conversion from RGB color space to HSI color space, the hue component remains unchanged, while the saturation component of Gamma Correction.

Due to the human visual sensitivity for brightness much stronger than the color shade, to facilitate processing and identification, it is often used the HSI color space, which is more consistent with the human visual characteristics than the RGB color space. Given the better visual processing effect while an appropriate increase in the saturation, the paper mainly uses Gamma correction [8] for the saturation component. Its formation is as follows:

$$S_1(x,y) = S_0(x,y).\hat{}\,\gamma. \tag{6}$$

where $S_0(x,y)$ is the saturation component of the original image; $S_1(x,y)$ is the processing saturation component; γ is the Gamma correction parameter, from lots of experiments, when the correction parameter is 1/1.3, it can accurately reflect the color image information.

The brightness component processing in the HSI color space

Given the flaw in the MSR algorithm, the paper introduces adaptive scale and a multi-parameter correction factor, which can better adjust a large halo phenomena and excessive enhancement phenomena.

With modern equipments diversification, people's choices have begun to tend to diversify, so the dimensions of the image pixel also begin to have more choices. To this end, it introduces the adaptive scale. The paper uses an algorithm which can be adaptive the size of the image pixel, and meet the details and overall requirements. The adaptive scales are chosen as follows:

(a) When the rows and columns of image pixel are even, it can directly obtain the Gaussian kernel from the above experiments: a small-scale is 2.5% of the product of rows and columns; a meso-scale is 12.5% of it, and a large-scale is 40 % of it;

(b) When the rows are even and the columns are odd, the value of rows does not change, and the value of column is decremented by one. The obtained is as a new Gaussian kernel: a small-scale is 2.5% of the product of rows and columns, a meso-scale is 12.5% of it, and a new large-scale is 40% of it;

(c) When the rows of image pixel are odd and the columns of image pixel are even, the value of rows is decremented by 1, the value of columns remains unchanged, The obtained is as a new Gaussian kernel: a small-scale is 2.5% of the product of rows and columns, a meso-scale is 12.5% of it, and a large-scale is 40% of it;

(d) When the rows and columns of image pixel are odd, the value of row and column minus one is as the new size of the image and obtains a new Gaussian kernel: a small-scale is 2.5% of the product of rows and columns, a meso-scale is 12.5% of it, and a large-scale is 40% of it.

Given the choice above the value of row and column, it is mainly based on the Gaussian kernel structure matching. When the selecting the Gaussian kernel is a size of a processed image pixel which is a fixed proportion value, the mismatch can be avoided.

In addition, when it estimates the reflection component of each luminance channel in a single-scale processing, it applies the multi-parameter correction factor [9], which enhances the proportion in the interest region of the entire image and improves the overall tone. The formula is following:

$$R(x,y)^{'} = \sum_{i=1}^{n} \lambda_i \left\{ \exp\left[\log I(x,y) - W(x,y) \times \log[F(x,y) * S(x,y)] \right] \right\} \tag{7}$$

where $W(x,y)$ is the pixel after the Butterworth filter processing. Each of the parameters is the same as the above.

After the MSR algorithm processing, the pixel will be negative and out of display range. Then it requires the pixel shift and compression to the display range. From lots of experiments, the gain/offset correction method is often mapped to display the grayscale range [10,11], the formulation is :

$$R_j(x,y) = G_1 \times R^{'}(\mathrm{x},y) + G_2 . \tag{8}$$

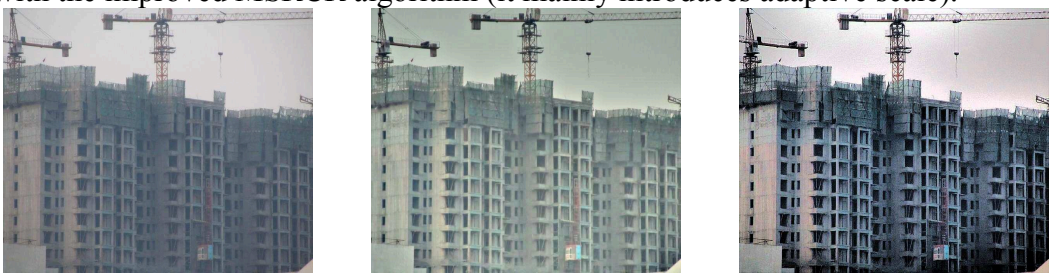
$$R_O(x,y) = 255 \times \frac{R_j(x,y) - R_{\min}}{R_{\max} - R_{\min}} . \quad (9)$$

where $R^{'}(\mathrm{x},y)$ is the input image; G_1 is the gain coefficient and G_2 is the offset, Thought lots of experiments, these two parameters may be a fixes value and does not affect the image processing effect, where the values are namely 3,50; $R_O(x,y)$ is the output image; $R_{\max}$ is the maximum value of the input image and $R_{\min}$ is the minimum value of it.

To make the details of images more prominent, this paper uses a Laplace operator custom filter to enhance edge profile details, after a Gaussian smoothing, and the overall integration of the image to achieve better processing effect. After the above processing, it is superimposed with the MSR algorithm processing image, and further uses the histogram equalization method in order to achieve the details more prominent and color more natural.

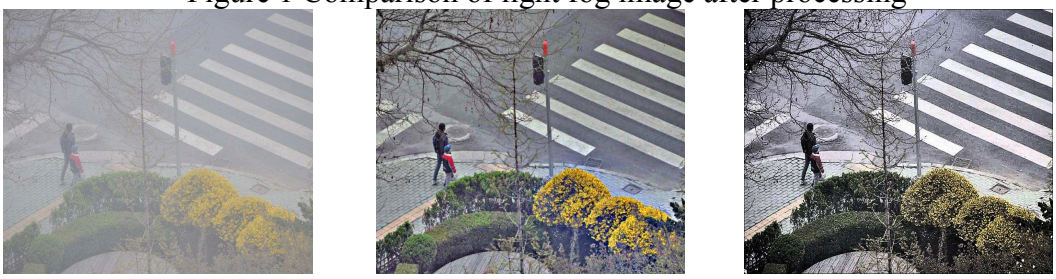
Experimental results and analysis

This experimental processing results shows in Fig. 1, Fig. 2, Fig. 3. In the experiment, the size of experimental image pixel are different, namely 669 × 1000, 900 × 651, 800 × 600, in which mainly contrast with the improved MSRCR algorithm (it mainly introduces adaptive scale).



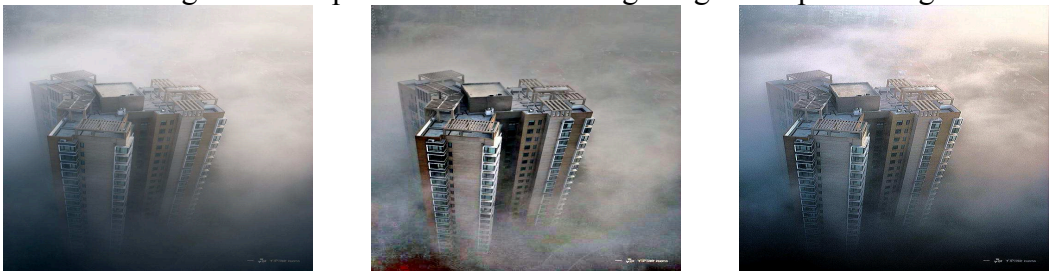
(a) An original image (b) An image after the improved MSRCR algorithm processing (c) An image after the new algorithm processing

Figure 1 Comparison of light fog image after processing



(a) An original image (b) An image after the improved MSRCR algorithm processing (c) An image after the new algorithm processing

Figure 2 Comparison of moderate fog image after processing



(a) An original image (b) An image after the improved MSRCR algorithm processing (c) An image after the new algorithm processing

Figure 3 Comparison of dense fog image after processing

From the results of the above, it can be seen that the algorithm can be adaptive adjustment in the different pixel and is better in details, brightness, contrasts and other aspects of processing. Although the improved MSRCR algorithm can meet with the change in the size of pixel, it introduces noise

after the Gaussian convolution processing. For the image processing effects, the paper will do comparison and evaluation from the contrasts (standard deviation), average gradient values and information entropy.

Table 1 The contrast of an image

The contrast of an image evaluation	The result of an original image	The result of the improved MSRCR algorithm processing	The result of the new algorithm processing
Figure 1	26.1528	43.2175	176.6955
Figure 2	32.3230	127.7746	373.7418
Figure 3	24.0906	71.5408	147.2442

The contrast of an image reflects the clarity. The greater the contrast is, the higher the sharpness of the image is, conversely, the lower [12] is. In Table 1, for the low-contrast image, the improved MSRCR algorithm improves the contrast 1.65-3.95 times, while the new algorithm improves 6.11-11.56 times.

Table 2 The average gradient of an image

The average gradient of an image evaluation	The result of an original image	The result of the improved MSRCR algorithm processing	The result of the new algorithm processing
Figure 1	0.7735	1.1939	3.4525
Figure 2	0.5835	2.3417	5.8337
Figure 3	0.6408	1.8165	2.3565

An important indicator is the average gradient in evaluation of image details. The average gradient can express the contrast of image details. In an image, when a gray level of an image has a large change rate, it is large [13]. From Table 2, after the improved MSRCR algorithm processing, the lowest increases 1.54 times, the highest increases 4.01 times; the image details have been greatly improved after the new algorithm processing, the lowest increases 3.68 times, the highest increases 10.00 times.

Table 3 The information entropy of an image

The information entropy of an image evaluation	The result of an original image	The result of the improved MSRCR algorithm processing	The result of the new algorithm processing
Figure 1	6.6930	6.9429	7.9873
Figure 2	5.9759	7.3924	7.9915
Figure 3	7.5855	7.1420	7.9805

For an image, the most important evaluation criterion is the information entropy, which reflects the average amount of information from the gray level of each pixel conveyed and can measure the importance of the target in the image. The higher the entropy is, the greater the amount of information containing is. From Table 3, the information entropy of the improved MSRCR algorithm can improve -5.8% -23.7% basically, which is mainly due to contain the color recovery coefficient and keeps the color of fog, also reduces the information entropy of an original image. But the information entropy of an image increases in the proportion of 5.2%-33.73% basically after the new algorithm processing.

Summary

In this paper, it proposes enhancement algorithm of color fog image based on the adaptive scale and multi-parameter correction. Combining with the characteristics of fog image, the saturation nonlinear Gamma correction can avoid the super saturation problem. In addition, multi-parameter correction for the tradition MSR algorithm, can reduce the noise from the Gaussian convolution, and avoids the halo phenomenon. Due to the algorithm processing only for the brightness, it saves much time. Through the subjective evaluation and objective evaluation, it is proved that the new algorithm

has a better effect on detail enhancement, color fidelity and clarity results comparing with the MSRCR algorithm processing.

Keyword: 3-D reconstruction; three-view; fundamental matrix; computer vision; photogrammetry; transformation parameters

Abstract. In order to realize efficient and stable 3-D reconstruction of image sequence, a novel 3-D reconstruction method is proposed based on independent three-view in this paper. Firstly, three-view is used as reconstruction unit. Consequently, robust fundamental matrix is calculated under the constraint of three-view. Then 3-D point cloud of 3-D scene corresponding to this three-view is rebuilt by triangulation. Because three-view point cloud is rigid body and local stable, 3-D point clouds of whole image sequence are unified to the same space coordinate system via calculating and using transformation parameters between adjacent three-view. Finally 3-D point cloud reconstruction of whole image sequence is achieved. As shown in experiment, method presented in this paper is simple, efficient and reliable.

Introduction

With the development of technology and the growth of demand about life quality, human have stronger and stronger desire to know and control the reality word. Obviously we are entering age of big data, which is thirsty for richer information about living environment extremely. As convenient is to realize objective digital description for real world, 3-D model has been getting widely attention, study and application in lots of fields. Consequently, acquiring of 3-D model, i.e. 3-D reconstruction, becomes an important fundamental task. 3-D reconstruction is a basic component both in computer vision and photogrammetry, and many methods have been proposed to achieved this goal. But, compared with classical reconstruction ways relying on modeling software or other expensive hardware equipment like 3-D scanner, method based on image sequence[1] has many advantages such as simple operation, Flexible application, and low cost. What's more, a vivid and objective result also can be obtained.

Key technologies related to 3-D reconstruction based on image sequence have been studied, summarized and realized in many articles[2,3]. And the whole process is mainly divided into four parts, they are feature points detecting and matching, robust calculation of fundamental matrix, camera calibration and 3-D reconstruction strategy. Striving to acquire improvement in fundamental matrix calculation and 3-D reconstruction strategy, a novel 3-D reconstruction method based on independent three-view is proposed in this article. Feature points detecting and matching is achieved using *sift*(Scale-invariant feature transform) algorithm[4] and Zhang Zhengyou method[5] is applied to get camera intrinsic parameters. Then the efficient and stable reconstruction of 3-D point cloud is achieved . Main innovations of this paper could be summarized as follows:

1 Fundamental matrix is computed robustly with high accuracy, using three-view as reconstruction unit and applying three-view constraint. What's more, there is no needs of calculating trifocal tensor any more.

2 3-D points cloud of each three-view is rebuilt and transformation parameters are obtained by common image between adjacent three-view. Finally, 3-D point clouds of whole image sequence are united into a completed point cloud model simply.

1 Introduction of 3-D Reconstruction Method Based on Independent Three-view

Calculation of fundamental matrix had been studied in lots of researches. *Ransac*（random sample consensus）algorithm is quite an useful robust approach, else some improved algorithms[6,7,8,9] based on it. However, most of those approaches are used under an assumption, that distribution of

matching point's residuals is changeless. So fundamental matrix could be computed robustly according to residuals' value. In fact, mismatch maybe also have little residual, and distributions of right matching points and mismatches are partially overlapping. Consequently, methods which use changeless residual distribution are not absolutely appropriate, because distribution of mismatches could not be adjusted based on actual situation. Advanced approaches[10] were proposed by researching distribution of matching points' residual. Methods [11,12]obtained improvement on accuracy and efficiency, selecting best matching point set via employing fuzzy clustering technology. Relying on constraint of epipolar geometry, those methods also have insufficient. When mismatches existing, those methods could not remove them absolutely, just getting a better matching point set as greater probability as possible. Trifocal tensor is a multiple view object in three-view, which could be described by geometry of "point-point-point" , owning stronger constraint ability than epipolar geometry. Fang Lei[3] excluded more mismatches between adjacent view in 3-D reconstruction process and achieved better results. As correctness of matching point has great influence in fundamental matrix calculation, the same way is employed to realize the robust correct computation of fundamental matrix by selecting more accurate matching point set.

In order to acquire 3-D point cloud of whole model correctly, 3-D point rebuilding form different three-view should be unified into the same coordinate system. Traditional iterative reconstruction method based on two-view is a common method. 3-D points' reconstruction of next image relies on accomplished points deeply. And matching point with next image and projection matrix must be computed for adding and reconstructing each image. It's not easy to get right matching points and projection matrix , so there are many disadvantages in such method. What's worse, there exists significant effect of error accumulation. A parallel iterative hierarchical reconstruction strategy[3] is presented, which is organized on the reconstruction unit of three-view. Compared with traditional iterative reconstruction method, it acquired improvement in accuracy and efficiency, with effective limit to error accumulation.

Regional network aerial triangulation algorithm[13] based on independent model is a classical strategy to realize 3-D reconstruction in photogrammetry. 3-D point cloud getting from independent image pair is a local and stable rigid body structure, so they could be unified by simple translation, rotation or scaling. Inspired by above two methods, a novel strategy based on independent three-view is presented. Considering local and stable point cloud structure could be obtained under three-view constraint, whole image sequence is divided into several three-views , also 3-D point clouds. Then transformation parameters are calculated by common image between adjacent three-view. Lastly, all of 3-D point clouds are unified into the final point cloud model. The whole process is shown as Fig. 1.

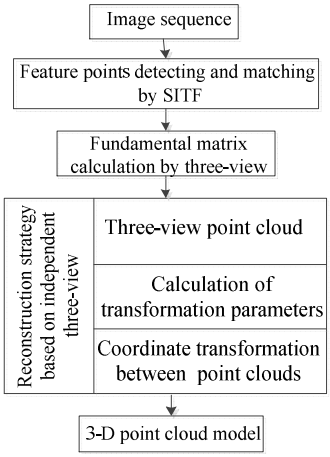

Fig. 1 Flow diagram of 3-D reconstruction

2 Calculation of Fundamental Matrix Based on Three-view

2.1 Three-view constraint

Three-view constraint - trifocal tensor, has analogous properties to the fundamental matrix of two-view geometry: it is independent of scene structure depending only on the relations between the views. The view matrices may be retrieved from the trifocal tensor up to a common projective transformation of 3-space, and the fundamental matrices for view-pairs may be retrieved uniquely.

The essence of the epipolar constraint over two views is that rays back-projected form corresponding matching points are coplanar, a weak geometric constraint, as left graph shown in Fig. 2.

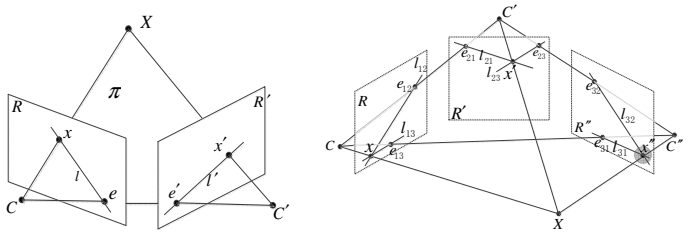

Fig. 2 Constraints of epipolar and three-view

C and *C'* are centers of the two cameras when getting images *R* and *R'*. Camera baseline *CC'* intersects each image plane at the epipoles *e* and *e'*, *x* and *x'* are image points which imaged by a 3-space point *X* in *R* and *R'*. Any plane π containing baseline *C C'* and point *X* is called epipolar plane, and interests image planes in corresponding epipolar lines *l'* and *l'*, *l'* is epiolar line of point *x*, and it passes through epipoles *e'* and point *x'*, corresponding point of *x* in another image. So, given a pair of images ,it was seen in Fig. 1, the epipolar geometry constraint can only guarantee that any point *x'* must lie on the epipolar line *l'*. But exact position where the point is could not be determined.

Compared with the epipolar geometry, three-view geometry owns ability to transfer from two views to a third: given a point corresponding over two views ,the position of the point in the third view is determined as the right graph shown in Fig. 2. e_{ij} represents epipole on the i^{th} image that is imaged from the j^{th} camera's center. Similarly, l_{ij} represents epipolar line on the i^{th} image of the projection point on the j^{th} image. *x*, *x'* and *x"* are the projection points of 3-space point *X* on the image *R*, *R'*, *R"*. they are corresponding points. So conclusion can be drawn from three-view constraint: any projection point on one image of three-view is the same with intersection of epipolar lines on the very image of its corresponding points.

2.2 Algorithm and experiment of the fundamental matrix calculation

To distinguish whether a pair of points are right matching points or not , distance(also called residual) form point to its matching point's epipolar line is always used as evaluation criterion in traditional robust algorithms. Guarantee that matching is right is not sure, even though the matching points have tiny residual. Suppose that there is a point *X* in 3-space, as shown in Fig. 3, *x* is its projection point in image *R* and *x'* should be another projection point in image *R'* . Because of detecting error, x_a' , x_b' and x_c' may be the undetermined points of *x'*. Distance of dotted line in Fig. 3 represents the magnitude of residual. Comparing residuals between x_a' and x_b' , it's easily to make sure that x_a' is the right one. Actually, x_c' has a smaller residual than x_a' ,and it's also possibly to be regarded as a correct matching point . But it is an error obviously.

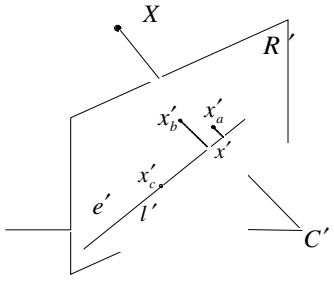

Fig. 3 Correctness judgment of matching points

Fig. 4 Three-view data for experiments

Three-view has stronger constraints between matching points. For an example as shown in Fig. 2 right, x and x' are the matching points, l_{31} and l_{32} are their epipolar lines on image R'', whose intersection should be the same point with point x'' in theory. Because of the noise produced during the extracting, shadow region as shown in Fig. 3, may be the area where real point x'' is. So distance between the intersection and real matching point should be limited to a certain threshold. In conclusion: distance between matching point and intersection of corresponding epipolar lines should be large, when matching points in three-view are not right. Based on that in this article, a more accurate matching point set is obtaining by getting rid of those mismatches .

Basic principle of this method could be described as follow. *Ransac* algorithm is frame of this approach, and matching point set is selected using constraint of three-view. Then fundamental matrix is acquired and used as initial value by M-Estimators method, to obtain higher accurate result. In order to verify the effectiveness of this algorithm, many experiments were conducted. 3 groups of experiment data are shown in Fig. 4, they were acquired using common fixed focus camera.

Because of the nonrepeatability of *ransac* method, result is averaged by 50 results for each experiment. What's more, the average distance between point to its epipolar line is used as evaluation criterion to describe algorithms' precision:

$$d = \frac{1}{N}\sum_{i=1}^{N} x_i' \boldsymbol{F} x_i \left(\frac{1}{\sqrt{(\boldsymbol{F}x_i)_1^2 + (\boldsymbol{F}x_i)_2^2}} + \frac{1}{\sqrt{(\boldsymbol{F}'x_i')_1^2 + (\boldsymbol{F}'x_i')_2^2}} \right) \tag{1}$$

N is number of right matching point. Experiments results are shown as Table. 1:

Table. 1 Results of the real images/pixel

Data	*ransac*		M-Estimators		Our Method	
	$\boldsymbol{F}_{12}$	$\boldsymbol{F}_{23}$	$\boldsymbol{F}_{12}$	$\boldsymbol{F}_{23}$	$\boldsymbol{F}_{12}$	$\boldsymbol{F}_{23}$
1st	0.3910	0.4070	0.3623	4.7255	0.2981	0.3253
2nd	0.4424	0.4159	1.8480	0.2714	0.2817	0.2590
3rd	0.3261	0.4338	0.2611	0.3133	0.2511	0.3124

Compared with *ransac* and M-estimators algorithm, method presented in this article gets obvious improvement in accuracy, being proved of an effective robust algorithm.

3 3-D Reconstruction of Image Sequence

For a image sequence containing n images, reconstruction strategy is mainly divided into 2 steps as shown in Fig. 5: (1) divide into several three-views and rebuild every point cloud;(2) calculate the transformation parameters between adjacent three-view.

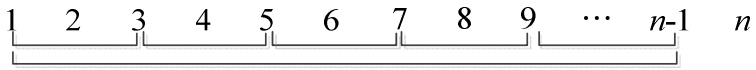

Fig. 5 Reconstruction strategy based on independent three-view

Firstly, image sequence is divided into several three-views(see Fig. 5), which have a common image with adjacent ones. (1,2,3)and (3,4,5) are adjacent three-views, image 3 is their common image. Fundamental matrix is acquired using method described in the 2nd section. Then 3-D point cloud is rebuilt by triangulation after getting projection matrix .Secondly, image point is selected on common image, whose 3-D coordinate should had been rebuilt in all the two three-views. Equations are formed according to selected points' transformation relationship. And then the transformation parameters are figured out simply. Now, the two key processes are going to be introduced in detail.

3.1 3-D point cloud reconstruction of three-view

Stable and accurate fundamental matrix has been obtained, then it can be upgraded to essential matrix with camera intrinsic parameters. We calculate and get the first two images' projection matrix by decomposing essential matrix[14]. Under the condition of central projection camera model, equation could be established without consideration of scale, for a image point $\boldsymbol{x}$ and its corresponding 3-D point $\boldsymbol{X}$, also its projection matrix $\boldsymbol{P}$:

$$\boldsymbol{x} = \boldsymbol{PX} \tag{2}$$

$\boldsymbol{x}$, $\boldsymbol{X}$ and $\boldsymbol{P}$ are expressed in homogeneous coordinates. One 3-D point has 3 elements, but only 2 equations can be established for one corresponding image point. So 3-D point must be computed when there exist at least a pair of corresponding points. For an example, there are a pair of corresponding points $\boldsymbol{x}=(x,y,1)$ and $\boldsymbol{x}'=(x',y',1)$ and projection matrices $\boldsymbol{P}$ and $\boldsymbol{P}'$, the 3-D point could be got by calculating following equations:

$$\begin{pmatrix} \boldsymbol{P}^1 - x_i\boldsymbol{P}^3 \\ \boldsymbol{P}^2 - y_i\boldsymbol{P}^3 \\ \boldsymbol{P}'^1 - x_i'\boldsymbol{P}'^3 \\ \boldsymbol{P}'^2 - y_i'\boldsymbol{P}'^3 \end{pmatrix} \boldsymbol{X}_i = 0 \tag{3}$$

i represents the i^{th} point, $\boldsymbol{P}^1$ is the 1st row of matrix $\boldsymbol{P}$. If corresponding points exist in every image of three-view, projection matrix $\boldsymbol{P}''$ of the 3rd image could be inversely calculated. Projection matrix has 11 elements and could be computed at the condition of points number no less than 6. Two equations could be established for each point.

$$\begin{bmatrix} X_i & Y_i & Z_i & 1 & 0 & 0 & 0 & 0 & x''X_i & x''Y_i & x''Z_i & x'' \\ 0 & 0 & 0 & 0 & X_i & Y_i & Z_i & 1 & y''X_i & y''Y_i & y''Z_i & y'' \end{bmatrix} \boldsymbol{p} = 0 \tag{4}$$

$(x'',y'',1)$ is the corresponding point on the 3rd image. $\boldsymbol{p}''$ is the vector representation for projection matrix, and $\boldsymbol{p}''$ could be calculated via SVD decomposition method.

3.2 Transformation parameters of 3-D point cloud

Coordinate transformation between different coordinate systems could be thoroughly described using 3 translation parameters, 3 rotation parameters and 1 scale parameter. Let's suppose that $\boldsymbol{X}=[X,Y,Z]^T$ and $\boldsymbol{X}'=[X',Y',Z']^T$ are the 3-D coordinates of a common image point in adjacent three-view structure, and the transformation relationship could be expressed as follow:

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = \lambda \begin{bmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{bmatrix} \begin{bmatrix} X' \\ Y' \\ Z' \end{bmatrix} + \begin{bmatrix} t_X \\ t_Y \\ t_Z \end{bmatrix} \tag{5}$$

λ is scale parameter. $\begin{bmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{bmatrix}$ is rotation matrix constructed by that 3 rotation parameters. $[t_X\ t_Y\ t_Z]^T$ is translation vector. Describing 3-D point in homogeneous coordinates, equation could be simplified and rewritten as follow:

$$\begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix} = \begin{bmatrix} a_1 & a_2 & a_3 & t_X \\ b_1 & b_2 & b_3 & t_Y \\ c_1 & c_2 & c_3 & t_Z \end{bmatrix} \begin{bmatrix} X' \\ Y' \\ Z' \\ 1 \end{bmatrix} \tag{6}$$

$\begin{bmatrix} a_1 & a_2 & a_3\ t_X \\ b_1 & b_2 & b_3\ t_Y \\ c_1 & c_2 & c_3\ t_Z \end{bmatrix}$ contains all parameters, spreading it and simpler expression is acquired: $\boldsymbol{W}=\boldsymbol{Ap}$.

$\boldsymbol{W}=[X,Y,Z]^T$, $\boldsymbol{A}=\begin{bmatrix} X' & Y' & Z' & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & X' & Y' & Z' & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & X' & Y' & Z' & 0 & 0 & 1 \end{bmatrix}$ is the vector and coefficient matrix constructed by 3-D point coordinates. Degree of freedom of $\boldsymbol{p}$ is 7, so it could be figured out when there exist 3 points at least. When number of points is more than 3, $\boldsymbol{p}$ also could be computed using SVD decomposition method ,or using following expression $\boldsymbol{p}=(\boldsymbol{A}^T\boldsymbol{A})^{-1}(\boldsymbol{A}^T\boldsymbol{W})$, relied on least square method principle.

4 Experiment and Summary

Image sequence shown in Fig. 6 is the input data used in our 3-D reconstruction experiment. 3 images in left of Fig. 6 are the enlarged display of three-view(1,2,3). Image sequence contains 35 images, whose size are 912×684, acquired using common fixed focus camera. Model of Camera is GR Digital III. Configuration of computer is *Intel* processor, with 2.00GHz clock speed and 2.00GB memory. All related algorithms are programmed by Matlab, using *matlab* vision 7.0.1. Whole process could be auto-completed by three steps after numbering for each image as shown in Fig. 6.

Fig. 6 Image sequence data and three-view (1,2,3)

Fundamental matrix of three-view (1,2,3) is calculated according to 2.2 section and 3-D point cloud is recovered according to method introduced in 3.1. 3-D point cloud is displayed form different angles as the 1st row shown in Fig. 7. Every 3-D point cloud of three-view is reconstructed with the same approach used in three-view (1,2,3). Transformation parameters between adjacent three-view are acquired using method described in 3.2. Regarding the 1st three-view coordinate system as datum, each three-view point cloud is transformed and unified. The 2nd row shown in Fig. 7 is the 3-D point cloud of whole image sequence.

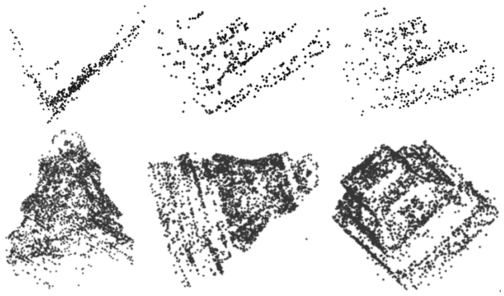

Fig. 7 3-D point cloud of three-view and whole image sequence

Actual image sequence data is experimented using method presented in this article and obtains ideal result. First step is feature points detecting and matching for 35 images, costs 11.7 minutes. The next step is recovering 3-D point cloud for each three-view, costs 2.5 minutes. The last step is computing transformation parameters between adjacent three-view, unifying point cloud and showing it. It costs 1.3 minutes. So the whole process costs 15.5 minutes altogether.

For each reconstructed 3-D point, its projective image coordinate could be calculated again by substituting itself into Eq. 2 with its corresponding projection matrix. Obviously, because of error, the reprojection image coordinate is generally not equal with its initial coordinate. So difference between them is commonly regarded as an evaluation criterion to prove method's performance, which also is called reprojection error. Average value of reprojection error for all 3-D points is computed on each image, and result is shown in Fig. 8. Most of the reprojection error is less than 1 pixel. What's more, the error accumulation is reduced effectively.

Image sequence used in our experiment is designed to be closed, that is to say, the 34th and 35th image are same with the 1st and 2nd image. If there is no error, 3-D point acquired from the 1st and 2nd images should has the same coordinate with that acquired form the 34th and 35th images. So difference between them also can be applied to describe method's performance. Because coordinate of 3-D point is relative, ratio of corresponding line segment is used as evaluation criteria instead of point's coordinate, whose value should be 1 in theory. 100 points are selected randomly existing on

image1, 2 and image 34, 35, accordingly C^2_{100} line segments are produced. Ratios of those corresponding line segments are computed and its statistics result is shown in Fig. 9.

Ratios between line segments mainly distribute around 1, and 96.4% of ratios locate between 0.94 and 1.03. However, there exist ratios bigger or smaller than1 obviously. Besides accuracy of algorithm should be improved further, distribution of points also is an important reason. If distance between points is little, tiny point error will produce huge influence on line segments ratio. But viewed as a whole, reconstruction realized by this method is reliable and ideal.

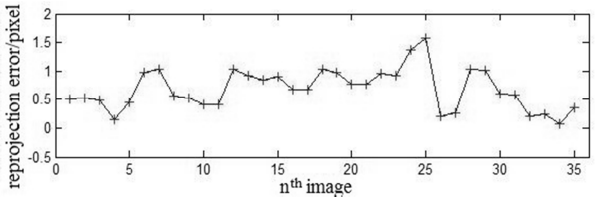

Fig. 8 Reprojection error of each image

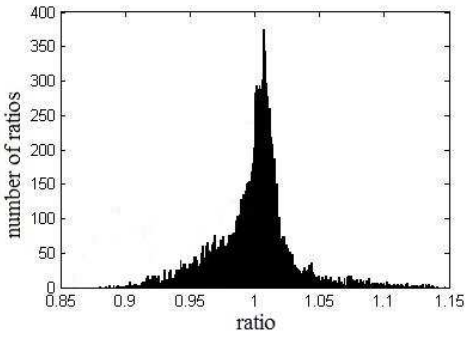

Fig. 9 Distribution diagram of line segments' radio

As reconstruction result and accuracy analyzing shown in Fig. 7,8,9, method proposed in this article acquires quite good 3-D point cloud reconstruction result, being proved to be a convenient, efficient, and reliable approach to realize 3-D reconstruction. Main advantages of this method can be concluded as follows:(1) three-view is used as reconstruction unit, acquiring accurate and robust fundamental matrix by three-view constraint , without calculation of trifocal tensor. what's more, stable and correct 3-D point cloud is obtained ;(2) reconstruction strategy based on independent three-view is proposed, which is simple and efficient. Of course, there also exist some insufficient need to be studied further, for example, the local optimization of independent three-view point cloud and the overall optimization of whole image sequence point cloud, also the implementation of parallel reconstruction strategy.

Study on Enhancing Terminal Identification in Track and Field Using Digital X-ray Photography Image

Guangjin Lai

Department of Fundamental Courses, Jiangxi Institute of Economic Administrators, 330038, Nanchang, China

Keywords: Digital; X-ray photography image; Terminal of track and field; Image processing; Cluster algorithm; MATLAB software

Abstract. Digital X-ray photography technology is under the control of the computer, to use one-dimensional or 2D X-ray detector to convert the captured image into digital signals directly to using image processing technology. It can realize the function of image analysis. We introduce X-ray photography technology into the terminal identification in track and field, and use the clustering algorithm to improve computer image clustering algorithm. Through capturing the digital signal of human head, arms and legs, it enhances the terminal recognition method in track and field. Finally we use MATLAB to calculate the captured image value of X-ray photography. Through calculation, motion capture and recognition of X-ray image are enhanced obviously. It provides a theoretical basis for researching on motion capture technology in track and field.

Introduction

Digital X-ray photography is also called the DR system, the system is mainly composed of three parts: including control module, electronic magazine, scanning module and image processing module. This system can use electronic magazine to convert X photon into digital image, which realizes the X-ray photography. In this paper we introduce the technology into the terminal detecting in sports. As the sprint speed of athletes is very high, the general photography instruments are difficult to achieve high precision capture, but X-ray detection technology can enhance the image effect, namely realizing the transient capture function and improving the quality of the image [1, 2]. It provides technical reference for image capture and image processing technology in track and field.

Overview of Digital X-ray Photography Image Processing

Digital X-ray photography image technology is a new type of computer photography image processing technology. It uses computer digital automatic control mode, and uses of X-ray photography method to convert the captured image into mathematical information, directly displaying the effective information [3, 4]. In this paper, we introduce this method into the capture and recognition in track and field, which improves the quality of images and enhances terminal recognition for staff in track and field competition. The specific process is shown in Figure 1.

Figure 1 shows the flow chart of X-ray image processing. It includes image preprocessing of X-ray, pre-processing of track and field, image digital conversion [5]. After taking image of athletes sprint at the terminal, the computer can analyze the error in a very short period and discriminate the ranking finally.

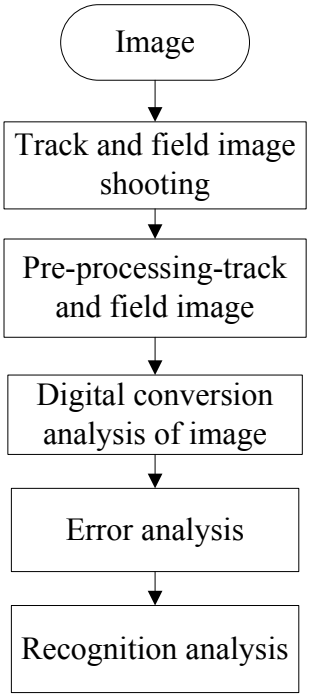

Fig. 1 Flow chart of X-ray image processing

Mathematical Model and Algorithms Design of Digital X-ray Image Processing

X-ray photography is mainly to capture the pixel; computer processing image mainly depends on the calculation of distribution and recognition error of pixel 6, 7]. The cluster algorithm is used to process the image, according to the distribution of pixels; the cluster formula is as shown in formula (1).

$$D=\frac{\sum_{j=1}^{m}\sum_{a_i\in b_i}K(a_i,b_i)}{\sum_{j=1}^{m}|B_i|}. \tag{1}$$

D is the clustering center function; m is the number of calculated pixel point; K is the distance of clustering center.

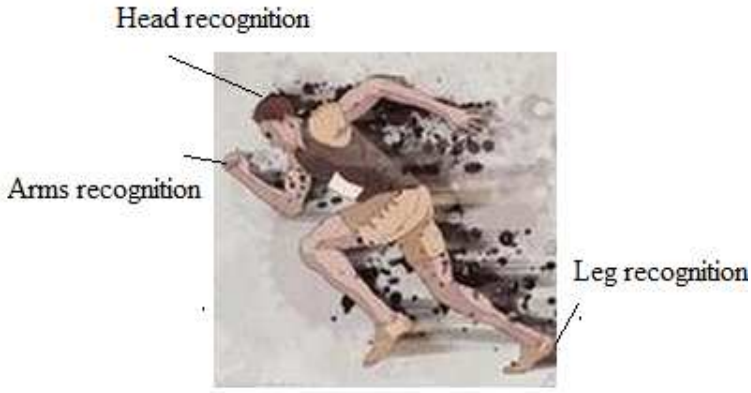

Fig. 2 Schematic diagram of gesture recognition in track and field sprint

Figure 2 shows the schematic diagram of 3D motion in the athletes' sprint. It uses X-ray photography to capture the motion of athletes, then uses computer to process image. In this paper, we establish digital output function of continuous two frames [8, 9]. Assume that continuous function of three parts of body is u,v. Then the similarity is as shown in formula (2).

$$W(u,v)=\begin{cases}s(u,v), & if \quad s(u,v)>2\\ 0\end{cases}. \tag{2}$$

$$s(u,v)=\sum_{p=1}^{5}s_p(u,v). \tag{3}$$

$$s_p(u,v)=\begin{cases}1 & if \quad u_p=s_p \\ & 0\end{cases}. \tag{4}$$

Among them, u_p and s_p are corresponding values of P item in u and s; $s(u,v)$ is the capture of successive frames. The specific process is as shown below:

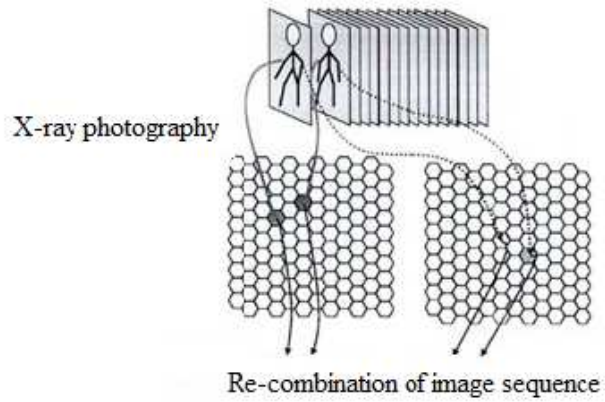

Fig. 3 Schematic diagram of motion decomposition data

Merging the frame, so the formula is as shown below:

$$U^p(t)=\bigcup_{r=1}^{K}Y_r^{\ p}(t), p=1,2...5, 1\le t\le l. \tag{5}$$

Among them, T is motion recognition function; l is the error range. In order to enhance the motion recognition at the terminal, we use MATLAB program to control the image recognition function. The main MATLAB programming is as follows:

```
unction f=myfun12(x)
f(1)=3*x(1)-2*x(2);
f(2)=-4*x(1)-3*x(2);
x0=[1;1];A=[2,3;2,1];
b=[18;10];lb=zeros(2,1);
[x,fval]=fminimax('myfun12',x0,A,b,[],[],lb,[])
goal=[18,10]; weight=[18,10]; x0=[1,1];
A=[2,3;2,1]; b=[18,10]; lb=zeros(2,1);
[x,fval]=fgoalattain('myfun3',x0,goal,weight,A,b,[],[],lb,[])
.....
```

Research on Application of MATLAB Image Processing in Image Enhancement at the Terminal of Track and Field

In order to verify the effectiveness and reliability of image processing cluster mathematical model and track pixel enhancement program designed in the second part, we use MATLABR2013a software to verify the effect of image processing, and design the computer system platform of X-ray photography image.

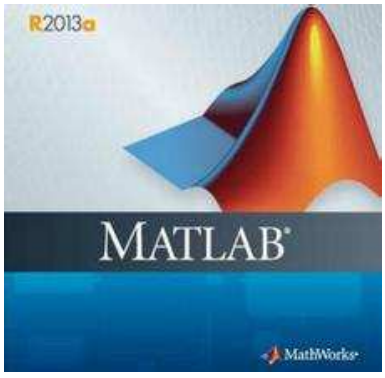

Fig. 4 Diagram of MATLAB starting window

Figure 4 shows schematic diagram of MATLAB starting window. In this paper we use the new version R2013a of MATLAB to capture the image shooting effect, and process the image effect of track and field terminal according to the distribution of pixels. The calculation process is as shown in Figure 5.

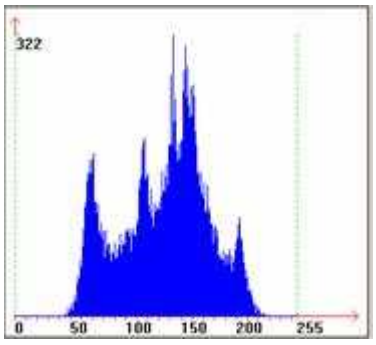

Fig. 5 Enhancement curve of pixel

Figure 5 shows the enhanced curve of pixel effect using MATLAB software. From it we can see, when the pixel is sparse, MATLAB will do enhanced curve encryption, and obtain the high pixel spectrum [10]. According to the position of spectrum we design the computer system platform of X-ray photography image, as shown in Figure 6.

Fig. 6 Computer processing image of X-ray photography image at the terminal of track and field

Figure 6 shows the computer processing image of X-ray photography image at the terminal of track and field. It use X-ray to capture the motion of the athletes at the terminal, and optimizes the system according to the shooting times and image processing time, which reduces the recognition error of the system.

Table 1. Calculation table of terminal error recognition using X-ray

Shooting times	Image processing time (s)	Error recognition rate (%)
1	0.128	99.28
2	0.179	99.35
3	0.098	99.47
4	0.146	99.59

Table 1 shows the calculation table of terminal error recognition using X-ray [11]. From the table we can see, the digital information processing speed of X-ray photography is more quickly, with only

0.098s; error recognition rate is up to 99.59%, . It is a efficient method of track and field terminal recognition.

Summary

In this paper we establish the cluster algorithm mathematical model of image processing, and introduce it into motion capture of consecutive frame, and use MATLAB programming to realize the function. In this paper, we introduce the X-ray photography technology into motion capture in track and field sports, and use the cluster algorithm to capture the motion continuously, and design using the clustering algorithm of image capture and image processing. We use the MATLAB to test the image effect captured by X-ray photography. Through calculation we find that image enhancement effect is obvious, and it reduces the error of motion capture. It provides a new method for computer image processing in track and field.

Track and Field Image Segmentation Technology of Automatic Multi-threshold Block Sampling Based on Matlab

Ali Yu

College of Physical Education, Jiangxi science and technology Normal University, Nanchang, 330013, China

Keywords: Block sampling; Genetic algorithm; Multi threshold; Image segmentation; Cross compiler; MATLAB programming

Abstract. Based on block sampling and genetic algorithm we improve the image segmentation technology, and obtain the new image processing method based on image pixel block cross reconstruction, and apply this algorithm to the block and the reconstruction calculation of track and field image. In order to verify the effectiveness and reliability of block sampling and genetic algorithm, we use MATLAB to test the algorithm. Through calculation, the number of 2D block is 20, the minimum number of 3D pixel array is 1259, and the calculation residual reaches the highest, with 0.0122. When the number of 2D block is 40, the maximum number of 3D pixel array is 3875, and the calculation residual reaches the lowest, with 0.0013. Therefore, according to the needs of computer hardware conditions, we can increase the 2D block number, improve the segmentation number of 3D pixel array for track and field image, which can reduce the residual and improve the precision of calculation.

Introduction

Multi threshold image segmentation has important applications in many fields in image compression, image analysis and pattern recognition, but the automatic selection of threshold has not been solved. In this paper, we use the block sampling technique to do image segmentation, and use copy and crossover of genetic algorithm to reconstruct the image, finally get the high resolution image. In this paper, we use MATLAB software to debug the algorithm, and through the image processing on the track and field running, get the residual curve changing with time [1, 2]. Finally, we do different 2D block processing on the image, get different 3D image array distribution point. It provides the theoretical reference for the study of sports image processing technology.

Application of Block Sampling Genetic Algorithm in the Image Segmentation of Track and Field

Image segmentation is split the image into a number of unique region, and extract the interested objects from the region. In order to analyze and identify the target, they need to be segmented and extracted [3, 4]. In this paper, we use the block sampling technique to do image segmentation, and reconstruct the image using the genetic algorithm. The specific process is as shown in Figure 1.

As shown in Figure 1, we use block sampling and genetic algorithm to calculate the image segmentation reconstruction algorithm, and use MATLAB to realize the genetic algorithm [5]. Finally we realize the optimization processing on the track and field sports image, and obtain high resolution images.

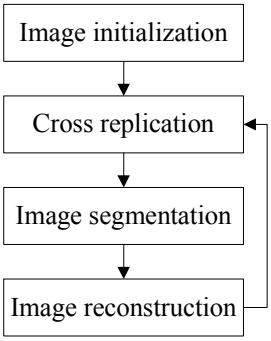

Fig. 1 The flow chart of image segmentation reconstruction

Block Sampling Genetic Algorithm Design of Track and Field Image Segmentation Reconstruction

Track and field image is mainly composed a series of pixels. Using block sampling technology can realize quick image division. Using the crossover and mutation feature of genetic algorithm can reconstruct image [6, 7]. First determining the image pixels set, pixel can be statistics to set boundaries. Pixel matrix can be written in formula (1) using the block principle.

$$\begin{matrix} 1 & a_{12} & \cdots & a_{1i} \\ a_{21} & 1 & \cdots & a_{2i} \\ \vdots & \vdots & \ddots & \vdots \\ a_{j1} & a_{j2} & \cdots & 1 \end{matrix} . \tag{1}$$

a_{ji} is block operation, the value of a_{ji} is greater, the higher accuracy of division. Based on genetic algorithm it can generate random sequence of image point, as shown in formula (2).

$$\{a_{t-1}, v_{t-1}^1, v_{t-1}^2, \cdots, v_{t-1}^n\}, a_{t-1} \in R . \tag{2}$$

Through the adaptive genetic algorithm we can do probability cumulative on the random sequence of pixel, finally get the cumulative formula as shown in formula (3).

$$b_c = \sum_{m=1}^{c} eval(\psi_m)(c = 1,2,\cdots,z) . \tag{3}$$

Doing cross operation on the random sequence of pixel. The cross process is as shown in formula (4).

$$\begin{aligned} \overline{a}_e^j &= xa_e^j + (1-x)a_e^j \\ \overline{a}_f^j &= (1-x)a_f^j + xa_f^j, j = 1,2,...,n \end{aligned} . \tag{5}$$

x is the cross coefficient, the coefficient is a random number, and $x \in [0,1]$.

Using genetic variation principle, we can do mutate operation on the pixel, as shown in the formula (5).

$$\{\overline{a}_e^1, \overline{a}_e^2, \cdots, \overline{a}_e^n\} = \{a_e^1, a_e^2, \cdots, a_e^n\} + N \bullet s . \tag{6}$$

N is a big positive number. S is random direction of n dimension space. In order to realize the genetic algorithm and block sampling of track and field image segmentation, this paper uses MATLAB to design the programming as below:

```
function [newpop]=crossover(pop,pc)
[px,py]=size(pop);
newpop=ones(size(pop));
for i=1:2:px-1
```

```
    if(rand<pc)
        cpoint=round(rand*py);
        newpop(i,:)=[pop(i,1:cpoint),pop(i+1,cpoint+1:py)];
        newpop(i+1,:)=[pop(i+1,1:cpoint),pop(i,cpoint+1:py)];
    else
        newpop(i,:)=pop(i);
        newpop(i+1,:)=pop(i+1);
end
end
Variation process MATLAB program
function
[newpop]=mutation(pop,pm)
[px,py]=size(pop);
newpop=ones(size(pop));
for i=1:px
    if(rand<pm)
        mpoint=round(rand*py);
        if mpoint<=0
            mpoint=1;
        end
.....
```

Application of Computer Image Processing Technology in Track and Field Image Segmentation

In order to verify the effectiveness and reliability of track and field image genetic algorithm designed in second part, we use genetic algorithm toolbox of MATLAB software to debug the program, and establish genetic algorithm system of track and field image processing [8]. The toolbox interface is as shown in Figure 2.

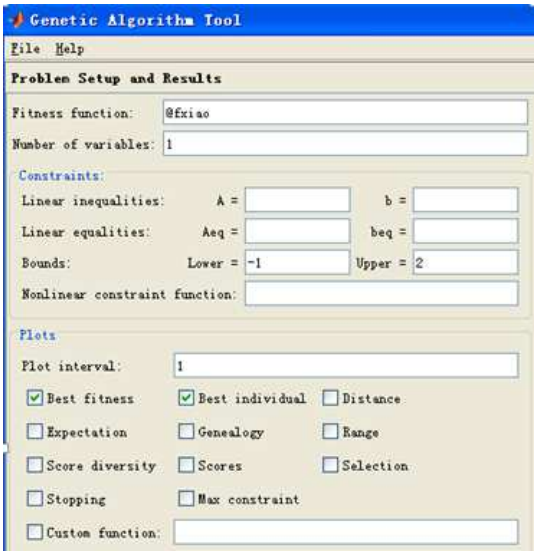

Fig. 2 Genetic algorithm toolbox of MATLAB

Figure 2 shows the genetic algorithm toolbox of MATLAB. It is in the MATLAB software. The module can achieve the genetic algorithm debugging function, where File can import the image processing program [8]. This paper uses the block sampling genetic algorithm to do segmentation reconstruction operation on the image. The residual convergence curve is as shown in Figure 3.

Figure 3 is the residual convergence curve computed by MATLAB. From the chart we can see, with the increase number of iterative, calculation gradually tends to be converge [9]. After 600 iteration, reconstruction iteration and segmentation iteration have reached a stable convergence

condition, the minimum residual is only 0.00016, which meets the requirements of design and calculation.

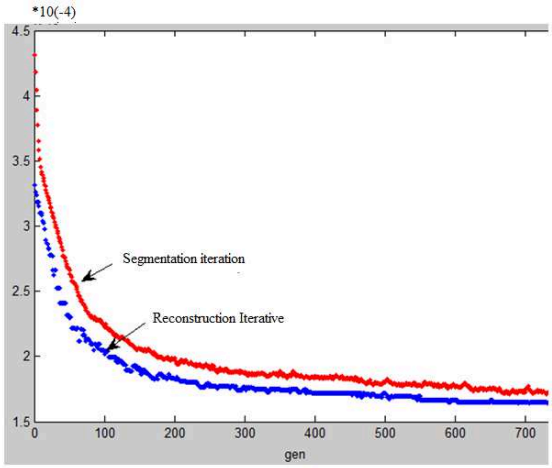

Fig. 3 The residual convergence curve

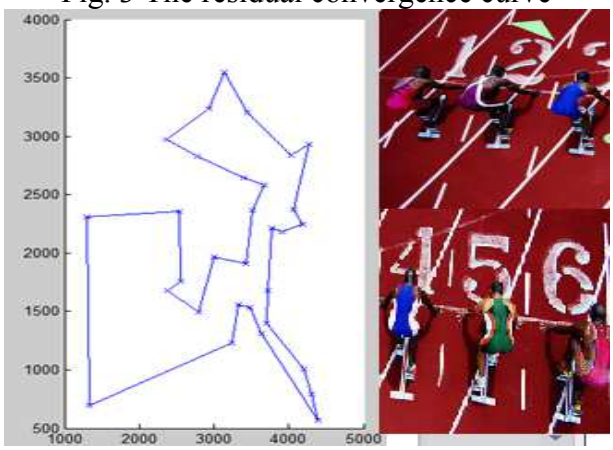

Fig. 4 The result of 2D image block

Figure 4 shows the 2D image block, MATLAB can achieve image block function. As shown in Figure 4, we do block segmentation on track and field image, use reconfiguration algorithm to synthetic images, and obtain 3D image point distribution as shown in Figure 5.

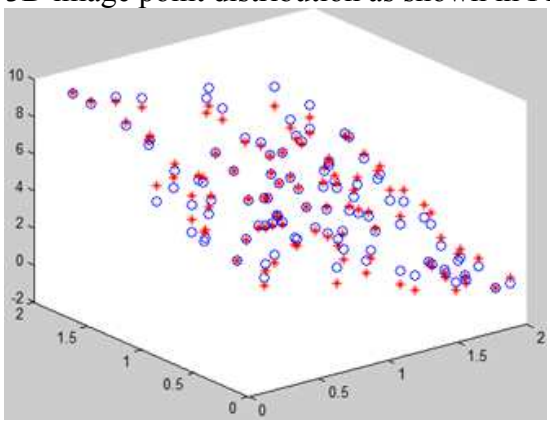

Fig. 5 The result of 3D image block

Figure 5 shows 3D image block sampling. It uses image segmentation theory to capture image sequences in 3D space, and maps pixel in 3D space. It uses crossover and mutation of genetic algorithm to reconstruct the pixel. The main data is as shown in Table 1.

Table 1. Result of image block segmentation

Number of 2D block	Number of 3D pixels	Residual
20	1259	0.0122
30	2456	0.0082
40	3875	0.0013

Table 1 shows the result of image block segmentation. From the table we can see, along with the increase number of blocks, the number of pixels increases gradually, but the residual is reduced. Through calculating we get the result of image segmentation reconstruction, as shown in Figure 6.

Fig.6 Diagram of track and field image diagram reconstruction

Figure 6 shows the effect of track and field image segmentation reconstruction using MATLAB genetic algorithm toolbox. From the chart we can see, the resolution of reconstructed image segmentation is improved, which is conducive to analyze the image details, and it improves the precision of image information processing.

Summary

In this paper we establish block sampling algorithm of image segmentation, and design the mathematical model of image reconstruction by using genetic algorithm, and obtain a new the block crossover reconstruction image processing of pixels. This method can realize the reconstruction calculation of the track and field image. We use MATLAB software to debug image segmentation reconstruction algorithm, obtain the residual curves changing with time. Combined with 2D block processing, we get the 3D pixel array distribution. Finally, we use the image block processing to optimize image, and get the high resolution images of track and field. It provides a new computer method for studying image processing technology.

Abstract. The system selected OmniVisiON company's CMOS chip OV7620, it is an integrated color camera chip, a 640 × 480 (300,000 pixels) image matrix. Considered that the CPLD control system is similar to the DMA mode of data transmission; Cypress's USB 2.0 chip is used by CY7C68013 chip. Finally, it is become the microcontroller firmware and device driver. The paper presents the design of Image acquisition system based on CMOS image sensor USB interface. Design an image acquisition and transmission system, and describes its firmware as well as the development of USB device drivers and PC-side application.

1. Introduction

Introduction of CMOS image acquisition system is the core of the CPLD con-trol, the system selects a colour image sensor OV7620 and fast image transmission through the USB interface which is similar to the DMA mode. Many applications of pattern recognition, computer vision, and multimedia ap-plications are increasingly have a high demands on the acquisition and transmis-sion of image data [1].

2. Image acquisition system

2.1 Image system acquisition

The system selected OminiVisiON company's CMOS chip OV7620, it is an integrated color camera chip, a 640 × 480 (300,000 pixels) image matrix in the interlaced mode, the operating frequency up to 60Hz progressive scan at 30/ s. Image plane size 1/3 inches to 8 or 16-bit digital signal from a single or dual channel output, the output signal type can be selected between YCrCb and RGB image matrix to support VGA or CIF regulations, the digital output format follow the the CCIR601 ZVPorts, CCIR656 or other standards [2].

The CPLD selection using ALTERA chip EPM7128S which is the core of the system that should not only be responsible for the OV7620 output video data are stored in SRAM, but also in conjunction with the MCU to complete the transmission of video data USB, as is shown by equation1.

$$M_{f,1} = \sum_{i=1}^{L} \sum_{j=1}^{L} h_{f,1}(i,j) \cdot \log_2 \frac{h_{f,1}(i,j)}{h_f(i) + h_1(j)} \tag{1}$$

MCU is the CIGNA company's high-performance microcontroller C8051F020, work and status of the CMOS chip via the I2C bus control, C8051F020 comes from SMBUS bus interface, I2C clock line SCL and the data line SDA can be assigned to the port pin through the crossbar [3]. MCU as the host of the I2C bus communication, using the OV7620 42H (Write), 43H (Read) as a slave address with the MCU communication.

$$f_c = \sqrt{\frac{1}{MN} \sum_{j=0}^{N-1} \sum_{i=1}^{M-1} [I(i,j) - I(i-1,j)]^2} \tag{2}$$

CMOS image sensors are larger due to the CMOS process technology which is not high, so that the sensor noise is in the application since the invention of the 1980s and the commercialization process has been slow. SRAM chip IS61LV5128AL, the chip for high-speed static RAM, storage time of about 10ns, and is enough speed to meet the requirements of OV7620, its 512KB of storage space is sufficient to store 30 million pixel video data (Bayer2pattern: each pixel consists of one word section of the RGB information) [4].The USB interface chip using the PHILIPS PDIUSBD12 chip, the chip supports USB 1.1 standard protocols and DMA transfer mode.

$$H_e = -\sum_{l=0}^{L-1} P(l)\log_2 p(l) \tag{3}$$

When the OV7620 set the stability for the work, it will output video data, as well as three important reference signals: frame synchronization signal SYNC, the HREF of the horizontal sync signal, and pixel clock signal PCLK. As is shown by equation4.

$$\begin{cases} C_{j+1} = HC_j H' \\ D^h_{j+1} = GC_j H' \\ D^v_{j+1} = HC_j G' \\ D^D_{j+1} = GC_j G' \end{cases} \quad (j = 0,1,2,\cdots,J-1) \tag{4}$$

In the low-end products, the quality of its picture is close to the low-grade CCD resolution, and related businesses hope to replace the CMOS device CCD so that efforts are being gradually become clear. CMOS sensor can be subdivided into: Passive Pixel Sensor CMOS and Active Pixel Sensor the CMOS.

2.2 The storage of the image

640 × 480 pixel output characteristics, 512KB of RAM is divided into 512 lines, each line 1KB space selected by the 10 address lines A0 ~ A9 passage within the address remember low-order address: the ADDR-L; high A18 ~ A10 a total of nineaddress lines strobe lines are recorded as high address: ADDR-H. Synchronized to ensure the OV7620 collection of data is written to the SRAM, CPLD macrocell design two address counters: ADDR-L low counters and high counters the ADDR-H.

$$\begin{cases} D^{\xi}_{j,F}(m,n) = w^{\xi}_{j,\max}(m,n)D^{\xi}_{j,A}(m,n) \\ \quad + w^{\xi}_{j,\min}(m,n)D^{\xi}_{j,B}(m,n) \quad E^{\xi}_{j,A}(m,n) \geq E^{\xi}_{j,B}(m,n) \\ D^{\xi}_{j,F}(m,n) = w^{\xi}_{j,\min}(m,n)D^{\xi}_{j,A}(m,n) \\ \quad + w^{\xi}_{j,\max}(m,n)D^{\xi}_{j,B}(m,n) \quad E^{\xi}_{j,A}(m,n) < E^{\xi}_{j,B}(m,n) \end{cases} \tag{5}$$

The high and the counter is cleared to 0, so that completion of an image data cache, detailed images acquisition signal timing shown in Figure 2. 512KB of SRAM chip is actually used and it has only 640 × 480 over 300 KB of storage space. Way the device works set to update the data on the falling edge of the PCLK signal: on the rising edge, the data is a period of stability, the falling edge of the PCLK signal to update the SRAM address signal ADDR; / WR signal at the rising edge of PCLK signal. CCD sensors combined with the analog signal generated by the component and then output to the third sensor followed by on, until the combination of the last sensor signal to form a unified output.

$$\begin{cases} D^{\xi}_{j,F}(m,n) = -(\left|w^{\xi}_{j,\max}(m,n)D^{\xi}_{j,A}(m,n)\right| \\ \quad + \left|w^{\xi}_{j,\min}(m,n)D^{\xi}_{j,B}(m,n)\right|) \quad D^{\xi}_{j,A}(m,n) < 0 \\ D^{\xi}_{j,F}(m,n) = \left|w^{\xi}_{j,\max}(m,n)D^{\xi}_{j,A}(m,n)\right| \\ \quad + \left|w^{\xi}_{j,\min}(m,n)D^{\xi}_{j,B}(m,n)\right| \quad D^{\xi}_{j,A}(m,n) \geq 0 \end{cases} \tag{6}$$

Then write data to the SRAM effectively. The CPLD control the SRAM write data logic using VHDL language, and finally achieve a continuous image data acquisition using MAX PLUS II tools for simulation design.

2.3 The storage of the image

The traditional USB transfer mode is the MCU start with SRAM data being sent to the PDIUBD12; by PDIUBD12 sent to the host. Regardless of the MCU to fetch data from the SRAM or to write data to the PDIUBD12 of the peripheral, the speed is slower. Therefore, we consider the CPLD control system is similar to the DMA mode of data transmission. In the working process, SCM is responsible for the interpretation of the USB control transfer.

$$\begin{cases} D_{j,F}^{\xi}(m,n) = \left| w_{j,\max}^{\xi}(m,n) D_{j,B}^{\xi}(m,n) \right| \\ + \left| w_{j,\min}^{\xi}(m,n) D_{j,A}^{\xi}(m,n) \right|) \quad D_{j,A}^{\xi}(m,n) < 0 \\ D_{j,F}^{\xi}(m,n) = -(\left| w_{j,\max}^{\xi}(m,n) D_{j,B}^{\xi}(m,n) \right| \\ + \left| w_{j,\min}^{\xi}(m,n) D_{j,A}^{\xi}(m,n) \right|) \quad D_{j,A}^{\xi}(m,n) \geq 0 \end{cases} \tag{7}$$

To be carried out from outside access number, the PDIUBD12 microcontroller allows the bus to complete the work by the CPLD. The CPLD generate external memory read signal and address to produce PDIUBD12 write signal and address, and the external memory data transmit to PDIUBD12 interface chip automatically.

2.4 The specific implementation of the data transmission

When a host needs to transmit data through the control pipe to send the request, the MCU receiving the order immediately after the OV7620 so that SRAM data bus, and to notify PDIUBD12 ready for the primary endpoint of the bulk data transfer, then the send TXCOM command signal to the CPLD,notify the CPLD to start transferring data; 64B of the data transfer is completed, the CPLD to the microcontroller send TXEND signal to show 64B transferred, and wait for next TXCOM signal, the next 64B transmission. MCU and CPLD through these two signals are in order to complete the handshake.

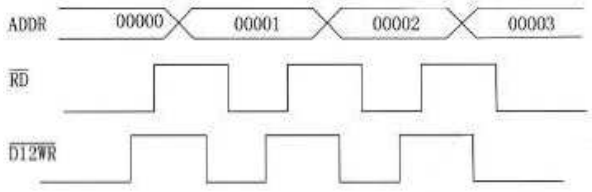

Fig. 1 Image transmission signal timing diagram

3.System software design

The system software includes a USB device firmware, device drivers and applications.

Device firmware is the core of the device when it is running, its main function is to control the interface chip PDIUBD12 and complete USB 1.1 protocol (including standard equipment request, vendor request processing, set the device interface, etc.).

What worth mentioning in the paper is that the microcontroller program of this system has an additional USB device firmware. The system also has single-chip OV7620 I2C control software and CPLD handshake procedure. All of the procedures is used the Keil C software to prepare for the programming, after the programming, we download it to the MCU in it.

$$\begin{cases} W_{\psi}^{H}(j,x_1,y_1) & \left| W_{\psi}^{H}(j,x_1,y_1) \right| \geq \left| W_{\psi}^{H}(j,x_2,y_2) \right| \\ W_{\psi}^{H}(j,x_2,y_2) & \left| W_{\psi}^{H}(j,x_1,y_1) \right| < \left| W_{\psi}^{H}(j,x_2,y_2) \right| \end{cases} \tag{8}$$

Second, we designed the device drivers in the Windows operating system within the running kernel level driver used to control the hardware, the USB device driver using standard WDM device driver while the WDM using the IRP as its drive mechanism.

In the development of this system, the driver DR IVERSTUD IO tools package provides a complete source code generation tool (DR IVER WIZARD) and the corresponding library.

$$w = \begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix} * \frac{1}{16} \tag{9}$$

For the application of Win2 system, in each device abstraction for files, the data is transmitted through a few simple file operations AP function to communicate with a device driver.

$$\begin{cases} w^{\xi}_{j,\min}(m,n) = \frac{1}{2} - \frac{1}{2}\left[\frac{1 - M^{\xi}_{j,AB}(m,n)}{1 - T}\right] \\ w^{\xi}_{j,\max}(m,n) = 1 - w^{\xi}_{j,\min}(m,n) \end{cases} \tag{10}$$

4. Conclusion

Optimal adjustment of the 2G/3G switching to a longer include an analysis of the adjustment, observation, and then repeat the process of analysis cycle also to go through step by step in order to gradually adjust and optimize the place. The refined optimization analysis of 2G/3G Mode Switching provides an efficient and practical way for users for reference.

Keywords: DPM 2D barcode; Homomorphic filtering; Binarization; Convex hull algorithm

Abstract: This paper studies the positioning method of DPM 2D barcode image. Because of the reflective problems of metal surface, the barcode image gotten will have uneven illumination, high light issues. In this paper, the homomorphic filtering method is used to enhance the image. Then the gradient projection is used to positioning the barcode region preliminary. We use an adaptive threshold method composed of Otsu method and neighborhood threshold method to solve the error segmentation problem. Finally the convex hull algorithm is applied to locate barcode region. Experiment results show that this method can effectively locate the barcode region quickly.

Introduction

Direct Part Marking[1] is a permanent identification technique that will mark permanent words or symbols on the products. DPM 2D barcode is kind of the two-dimensional barcode which mark symbols on products by using DPM technique. Traditional Data Matrix 2D barcode positioning method cannot recognize the barcode effectively. This paper studies the barcode image enhancement and binarization method. A method to positioning the barcode image dotted Data Matrix 2D barcode marked on metal surface by laser is proposed in this paper.

Enhancement method of DPM 2D barcode image

Because of ambient light and surface quality of the metal, the barcode images gotten always are affected by uneven illumination and high light. So the barcode image need to be enhanced in order to be recognized. There are many uneven illumination image processing algorithms such as histogram equalization, homomorphic filtering and enhancement method based on Retinex theory. Classic homomorphic filtering is processed in the frequency domain. It will take a long computing time and need a large memory space. In this paper, we propose an improved spatial homomorphic filtering algorithm combined with the Kronecker product[2]. The algorithm procedure is shown in Fig. 1.

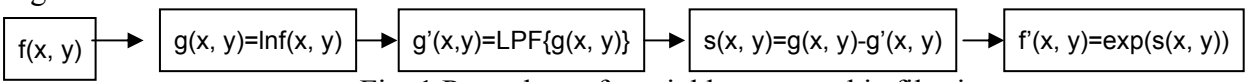

Fig. 1 Procedure of spatial homomorphic filtering

In order to approximate the low-pass filter using neighborhood average method, a larger range of neighborhood will be needed. This will definitely increase the computational complexity. Using Kronecker product principle, the two-dimensional array of neighborhood templates will be divided into two one-dimensional arrays. It will greatly improve computing speed. Fig. 2 is the result of this method.

(a) Original image (b) Enhanced image

Fig. 2 Image enhance by homomorphic filtering

Binarization method of barcode image

In order to get the binary barcode image, we use an adaptive binarization method composed of Otsu method and nearest neighbor pixels contributing threshold method[3]. In this way, all pixels of the image are divided into two groups by a sliding window firstly. Then we can move the sliding window from pixel to pixel. If the change of grayscale is great within the sliding window, the current pixel is divided to A group. Otherwise the pixel is divided to B group. The divide procedure is shown in Eq. 1.

$$\begin{cases} \frac{1}{\mathrm{N}}\sum_{i=-r}^{r}\sum_{j=-r}^{r}\left|g(x+i,y+j)-\overline{g}\right| \geq k*g' & g(x,y)\in A \\ \frac{1}{\mathrm{N}}\sum_{i=-r}^{r}\sum_{j=-r}^{r}\left|g(x+i,y+j)-\overline{g}\right| < k*g' & g(x,y)\in B \end{cases} . \tag{1}$$

Where r denotes the size of sliding window, g(x, y) denotes the grayscale value of each pixel and g' denotes the mean grayscale value in the sliding window, k is a ration of the average value and standard deviation of all pixels in the sliding window.

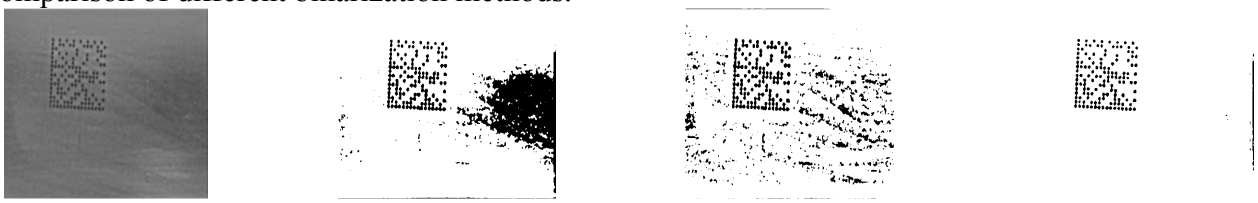
The result of segment is related to the size of sliding window. Table 1 shows the result of classification with different size of sliding window. Experiment results show that size of 7*7 is the best size of the sliding window.

Table 1 Classification result with different size of sliding window

Size of window	3*3	5*5	7*7	9*9
Result of classification				
For the pixels in A group, the OSTU method is used to find the threshold T. If the grayscale value of the pixel is greater than T, the pixel can be marked as background pixel. Otherwise it will be marked as target pixel. For the pixels in B group, we use nearest neighbor pixels contributing threshold method. For one pixel in B group, search the 8-Neighbor pixels first. If the target pixels and the background pixels can not be found in the eight neighborhood, the scope of the search will be expanded. The search area will be enlarged to 16-Neighbor pixels, 24-Neidhbor pixels. The segmentation method is given in Eq. 2.

$$f(x,y)=\begin{cases} 255 & \left|f(x,y)-g'_b\right| > \left|f(x,y)-g'_w\right| \\ 0 & \left|f(x,y)-g'_b\right| \leq \left|f(x,y)-g'_w\right| \end{cases} . \tag{2}$$

Where g'_b denotes the average gray value of all pixels belong to background and g'_w denotes the average gray value of all pixels belong to target. According to the feature of dotted Data Matrix 2D barcode, we determine a threshold There. When search area is larger than the threshold T, searching process will be stopped. The current pixel will be marked as background pixel. Fig. 3 shows the comparison of different binarization methods.



(a) Original image (b) One-dimensional Ostu (c) Two-dimensional Ostu (d) Method in this paper

Fig. 3 Comparison of different binarization methods

DPM 2D barcode localization

The Data Matrix barcode is composed of two solid adjacent borders in an "L" shape (called the "finder pattern"). In this paper, we locate the Data Matrix 2D barcode with convex hull algorithm[4].

Firstly, we use mathematical morphology to fit the “L” shape of the Data Matrix 2D barcode[5]. Fig. 4 is the result of closing operation.

(a)Original image

(b)Closing operation

Fig. 4 The result of closing operation

n this paper, we use Sobel operator to get the border of polygon. Then the convex hull points of polygon are calculated by using Graham scan method. In the standard Data Matrix 2D barcode, there will be 5 convex hull points. Because there are interference points around the areas of the image barcode, the amount final convex hull points detected may be much more than the expected points. It will reduce the locating accuracy. So these noise points should be removed. Finally, we can get the polygon which consisted of convex hull points. If “L” shape exists in the current convex hull polygon, stop calculating. Otherwise, the next polygon will be detected. The result is shown in Fig. 5.

(a) Original image

(b) Locating result

Fig. 5 Locating result by using Convex hull algorithm

Conclusions

In this paper, we use homomorphic filtering method to solve the issues of low contrast, uneven illumination in the DPM barcode image. Then we use an adaptive binarization method which combined the gray contribution information and space contribution of pixels. Finally, we use convex hull algorithm to locate DPM 2D barcode. The experimental results show the locating accuracy of this method is pretty high.

Keywords: DS, UWB, Multipath channel, RAKE receiver

Abstract. Ultra-Wideband (UWB) wireless communication is a new potential communication technology currently in its field. It becomes very popular in the world since it's high performance, low radicalization and low cost. Currently UWB wireless system, we can call it Impulse Radio technology too, be invented in 20 century 1960s. But it was only used in military affairs field, bailout searching, radar location and so on. After civil using, it usually is used in indoor wireless LAN .In this paper, the development and application of UWB are introduced, the characteristic and limitation of UWB are simply analyzed. According to the simulating depending on Multipath channel, it shows increasing SNR about 1.5dB to the base of primary power district or increasing SNR about 1dB to primary power district and minor power district, we can get whole performance of RAKE receiver in perfect channel.

Introduction

UWB communication is also called the very narrow Pulse communication (Ultra Short Pulse), Impulse Radio (Impulse moisturizer Radio), etc. Tens of megabytes per second rate is used to transmit and receive no carrier frequency narrow pulse signal, the pulse width for less than 1 ns. Information communication is modulated to the precise time interval, including a Modulation method called Pulse Position Modulation (Pulse Position Modulation), due to cover many communication frequencies, it uses the random sequence jump time extension signal spectrum, makes the spectrum characteristics similar to white noise and has a very low power spectral density. Signal has low interference, low probability of intercept and time domain secret communication. As a kind of ultra wideband spread spectrum communication, it has more user capacity than now. Due to the use of less than 1 ns for narrow pulse signal of the carrier, it has the very good time resolution, almost not affected by multipath interference, and very suitable for indoor multipath environment complex applications of high-speed wireless local area network (LAN). From the existing technical indicators, in UWB wireless communication it has the most attractive index: high speed and low power consumption, so the research of UWB communication is of great significance [1].

UWB wireless communication can be divided into two kinds: carrierless UWB and carrier modulation UWB. Carrier modulation UWB has a variety of implementation scheme, the main two are based on DS - CDMA (Direct Sequence Code Division Multiple Access) and MB - based OFDM (Multi - Band Orthogonal Division Multiple). Different solution strengths and different applications may choose different scheme, other factors such as performance; complexity, price, etc will greatly affect the various solutions. There is still other UWB system scheme, especially in specific areas, such as military field. Research of UWB technology in our country and international standards, began almost at the same time, and get the support of national 863 plan, but compared with international advanced level, there are still a certain gap. In the set of standards/specifications, the United States, Europe, Japan and Singapore has carried on the related work, especially the United States, since releasing the preliminary rules of UWB communication, UWB technology research and development work has entered a new stage, many colleges and institutes are going on, and the UWB communications standardization of our country has not officially began to work. This work should be started as early as possible, so as to prompt the strength of research institutions and enterprises to participate in, to speed up the research and development work, to have more our own independent intellectual property rights related technologies and standards, to avoid more backward and huge losses in the international competition. In applications, according to the technical level of our country,

we can grasp the time to develop some low rate of product to seize the market first of all, we should constantly improve product performance, extend the range of products under the premise of stepping in technology research and development at the same time. In order to compete with the international advanced products [2,3].

In this paper we briefly introduce the development history of the concept of UWB content, the theory of ultra-wideband very narrow pulse signal is described and analyzed, through the computer simulation research of DS - UWB Rake receiver in multipath channel performance, finally draw the conclusion.

UWB system

An overview of the UWB system. According to the Shannon (c. E.Shannon) channel capacity

$$C = B\log_2(1+\frac{S}{N}) \tag{1}$$

We can increase the system transmission bandwidth B to keep the channel capacity C unchanged when the signal to noise ratio of S transmitted in Gaussian channel system falls, in order to achieve error-free communication channel. Step by step, it is from frequency hopping to spread spectrum communication, then to the ultra wideband (UWB) communication in the perspective of the development of communication technology. The bandwidth of the spread spectrum communication system is hundreds or even thousands of times greater than conventional communication system. Compared with the ultra wideband (UWB) communication, spread spectrum communication is a kind of narrow-band communication system, so the ultra wideband communications is bigger than the channel capacity of spread spectrum communication. Shannon also points out that under Gaussian noise interference, limited on the average power of the channel, to achieve effective and reliable communication signal is white noise statistical characteristics of signal, because Gaussian white noise signal has ideal autocorrelation properties. Gaussian white noise signal power spectrum is

$$s(\omega) = \frac{N_0}{2},\ -\infty < \omega < \infty \tag{2}$$

The autocorrelation function of it is

$$R(\tau) = \frac{1}{2\pi}\int_{-\infty}^{\infty} S(\omega)e^{j\omega\tau}d\omega = \frac{N_0}{2}\delta(\tau) \tag{3}$$

Ultra-wideband namely in the process of communication signal spectrum width is more than usually occupied bandwidth occupied the information system. According to the federal communications commission (FCC) definition of signal bandwidth is greater than 1.5 GHz, or the ratio of the signal bandwidth and center frequency is more than 20% for ultra broadband; The ratio of the signal bandwidth and center frequency between 1% ~ 20% for broadband, less than 1% for narrow band. The FCC then rule more than 500 MHZ bandwidth can be called ultra broadband [4].

The characteristics of the UWB wireless communication system. Modern UWB wireless communication technology has the excellent properties inherent resistance to multipath fading, it has a strong ability of market competition compared with the traditional wireless communication technology by the channel capacity of UWB, wide space, high Capacity (Spatial Capacity), low noise level of the power spectral density, strong anti-interference ability, dynamic adjustment data rate, power consumption and adaptive ability, almost all digital communication of simple structure, and thus can provide cost-effective wireless electric equipment. UWB pulse technology can be widely used in personal communication, high-speed LAN, cordless telephone, security detection, close to the high precision positioning etc.[5].

DS-BPSK modulated pulse ultra broadband simulation system.

Relative to the carrier system, pulse ultra wideband system is relatively simple and more. It realizes the most important is to solve the problem of precise timing and multi-user access, based on the timing of better, the system can provide multiple access good, better reflect pulse communication

advantage. The following part is to study the multi-user access timing good condition and receiving problems. Need to distinguish between different users in wireless communication.

The pulse waveform in Fig. 1 by the CM1-CM4 channel, because of the dense multipath channel, pulse waveform can no longer maintain visual shape, Fig. 2 shows in direct sequence spread spectrum pulse waveform of an chip by the corresponding waveform channel [6,7].

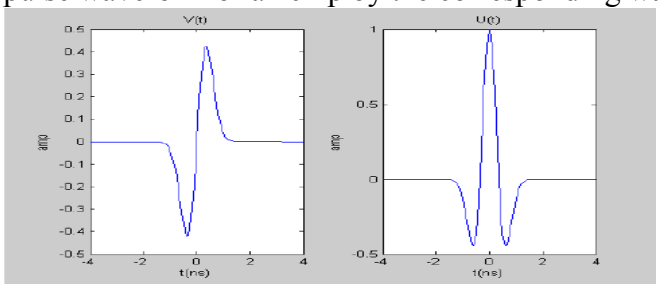

Fig.1 Gaussian pulse waveform and differential form Monocycle

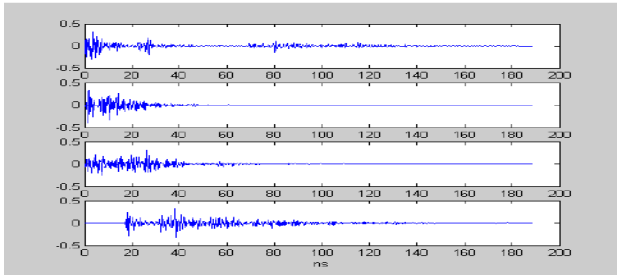

Fig.2 The direct sequence spread spectrum the differential form of Gauss is a channel impulse response chip

Now use that type, according to the selected Gold codes random equal probability binary sequence and baseband data rate, the ideal channel , Intel CM1-CM4 channel, statistics of a number of Monte Carlo simulation results on the same interval: $SIR \in (0,0.05)$

The results indicate that the actual chips interference is not serious, although the response waveform of CM1-CM4 channel is more complex and larger differences, but the performance under ideal received similar. The whole system simulation results also confirm that, in the ideal channel estimation for receiving, CM1-CM4 channel with similar performance, as a contrast, compare performance 63 bit Gold sequence and random binary sequence are three users, see Fig. 3 and Fig. 4

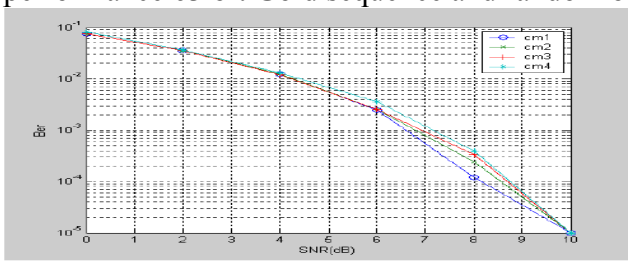

Fig.3 Gold sequence in CM1 - CM4 channel simulation results

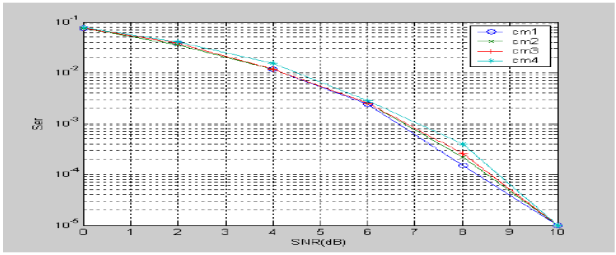

Fig.4 Random equal probability sequence in CM1-CM4 channel simulation results

In Fig.5, four curves were 63 bit Gold code as the user code, the simulation results in CM1-CM4 channel. Simulation results and theoretical analysis results are similar, namely, although four kinds of channel models in ultra wideband communication difference is bigger, but due to the interference between the chip produced by the multipath effect is small, the resulting four curve pretty close.

In Fig.6, the four curves are 63 bit equal probability random binary sequence as the user code, under CM1-CM4 channel simulation results, analysis as Fig.8.

At the same time, using the Gold code and the equal probability of random binary sequence as the user code, the curve is very similar. This shows that, in the channel condition and parameter selection, as long as the user code with pseudo random (random) characteristics and basic equal to the number of 0 and 1 in the code element, the bit error rate is very similar.

For comparison, Fig.6 shows the 63 bit Gold codes and equal probability random binary sequences of CM1 and CM4 bit error rate curve. Fig.9 can be seen, in the same channel, with two yards in the performance difference is small, only in different channels to different.

Research of Rake receiver performance. System simulation using low pulse transmission cycle, receiving the multipath energy .Although you can take small duty cycle to reduce chips interference, but in UWB communication, the channel response is more complex and the multipath

effect is relatively long, so it is necessary to study the Rank receiver receives the path number. This is a compromise between the receiving performance and receiving complexity [8, 9].

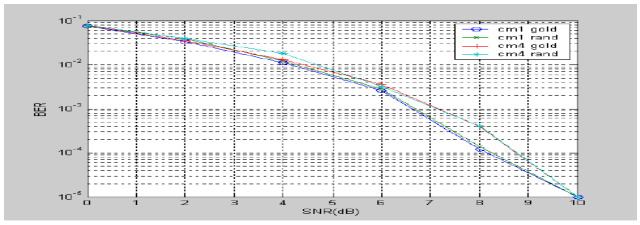

Fig.5 Gold codes and almost random binary code comparison

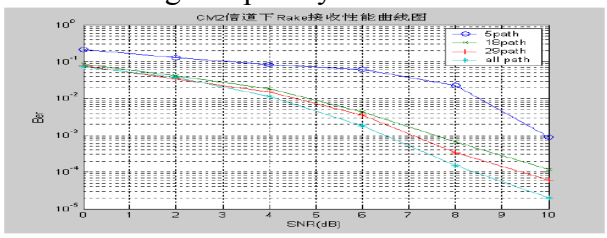

Fig.6 Rake receiver performances in CM2 channel

The simulation results in Fig.6. It can be drawn from the performance curve, as long as the receiving major path energy can achieve good effect. This is very useful for design of the receiver. From the curve in the graph can be seen, with a very small paths (5paths in figure) received, performance is not guaranteed, but the primary energy region receives (18paths in figure) can achieve better performance when receiving, the primary energy region and the secondary energy region receiving (29paths in figure) compared with the all Rake receiving (all paths in figure) has similar performance. As can be seen from the figure, on the basis of receives in the primary energy region increases 1.5dB, or on the basis of primary energy region increases in 1dB SIR, which can reach the performance of all Rake received under the ideal channel estimation.

Conclusions

The channel characteristics of UWB wireless communication system is dense multipath. Select the user code in UWB wireless communication system for system improvement is not obvious, the research results show that in choosing a random (pseudo random) characteristics of orthogonal user code, basically similar in performance .In our proposed MBOK (M-ary bi-orthogonal keying) scheme design in the future, by Walsh codes as multi user code. In the condition of big Duty ratio, direct selection of orthogonal code can get the best performance. In the chips interference can be used when the pseudo random sequence, such as Gold code, a little performance loss. At the receiving end, don't need to receive all the diameter of the energy, according to the statistical properties of the channel using appropriate tap number receiving multipath signal, can obtain a better signal-to-noise ratio, and simplify the design of the receiver.

Keywords: Foreground enhancement, Hidden Markov Model

Abstract. Foreground detection is an important part in video surveillance system. The detection results will significantly affect the performance of tracking, abnormal behavior analysis and other following procedures. Many algorithms have been proposed to improve the detection performance. However, these algorithms simply focus on one single frame, ignoring the relationship among the detection results of one target in successive frames. This paper presents a novel foreground enhancement algorithm using Hidden Markov Model (HMM). In a video sequence, one target in successive frames usually has similar shape, size, et al. With this property, the target can be modeled by HMM and enhanced using the result of its prior frame. The observation of HMM is obtained by ViBe. The enhancement result is then estimated by using Maximum A Posteriori (MAP). Experimental results show that compared with the state-of-art algorithm, the proposed method can enhance foreground detection effectively.

Introduction

Foreground detection is an important technique in computer vision and have been widely used in different applications [1-5]. The simple methods [6-7] are basically based on subtraction of a fixed background image or certain simple background model. The complex methods build sophisticated models for every pixel or region in the frame, using parametric models[7-10] and non-parametric ones[11-13]. There are also other foreground detection techniques, such as using color and gradient information [14], Eigen-backgrounds [9] and recently proposed ViBe [15, 16].

The foreground detection techniques mentioned above have a common weakness: they all perform foreground detection procedure on a single frame and ignore the relationship between two successive frames of the sequence. In this paper, the relationship between two successive frames is considered and the Hidden Markov Model (HMM) is used to model the relationship. A foreground enhancement algorithm is proposed based on this model. After obtaining the foreground detection result, the HMM is used to update the detection result.

HMM in Video Sequence

Framework. The Hidden Markov Model (HMM) is a doubly stochastic model which consists of states and observations. The state X_k in time k only depends on the state X_{k-1} in time k-1. The observation Y_k in time k is depending on the state X_k. In a video surveillance system, each target has its own shape, and this state is related to the state that belongs to the same target in the prior frame. The foreground detection result of each frame is related to the shapes of the targets in the frame. So the detection result of one target in prior frame can be used to update the result of the corresponding one in the current frame. The detection procedure of each target can be modeled as a HMM which is shown in Fig. 1.

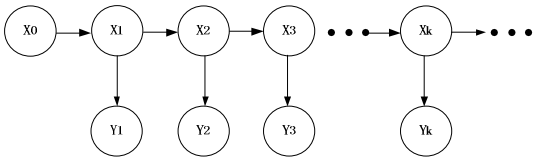

Fig.1 The HMM model of one target. X_k is the state and Y_k is detection result.

In practice, the enhancement of the whole target can be split into the updates of its pixels. Suppose x_k is the state of one pixel in time k, x_k is binary: 1 represents the pixel is foreground and 0 represents background; y_k is the observation result of the pixel in time k and is also binary.

To determine whether a pixel of one target in time k is foreground or not, the posterior probability $\Pr(x_k \mid y_{1:k})$ of the pixel must be calculated:

$$\Pr(x_k \mid y_{1:k}) = \frac{\Pr(y_k \mid x_k, y_{1:k-1}) \Pr(x_k \mid y_{1:k-1})}{\Pr(y_k \mid y_{1:k-1})} \tag{1}$$

In (1), the prediction probability $\Pr(x_k \mid y_{1:k-1})$ is sum of the production of posterior probability and transition probability in time k-1; the state x_k and the observations $y_{1:k-1}$ are independent given the state x_{k-1}, thus the posterior probability $\Pr(x_k \mid y_{1:k})$ can be rewritten as:

$$\Pr(x_k \mid y_{1:k}) = \frac{\Pr(y_k \mid x_k) \sum_{x_{k-1}=0,1} \Pr(x_k \mid x_{k-1}) \Pr(x_{k-1} \mid y_{1:k-1})}{\Pr(y_k \mid y_{1:k-1})} \tag{2}$$

Observation: Foreground Detection. The observation of the proposed HMM is obtained using the Visual Background Extractor (ViBe). It initializes the background model of one pixel from a single frame and randomly picks pixels from the pixel and its neighbors to build the model. When updating the model, it randomly updates one sample from the model and one from the model of its neighbors.

Enhancement: Using HMM. After detection and shadow elimination, the posterior probability $\Pr(x_k \mid y_{1:k})$ of one pixel can then be calculated by (2).The Maximum A Posteriori (MAP) estimation is used to determine the state of a pixel with $\Pr(y_k \mid y_{1:k-1})$ the same to both states (i.e. 0 or 1) of x_k in time k:

$$x_{\text{kmax}} = \arg\max_{x_k \in [0,1]} \Pr(y_k \mid x_k) \sum_{x_{k-1}=0,1} \Pr(x_k \mid x_{k-1}) \Pr(x_{k-1} \mid y_{1:k-1}) \tag{3}$$

The posterior probability is calculated after the corresponding blobs are found in two successive frames. The overlap region R of the bounding boxes of two corresponding blobs can be acquired after they are found using template matching. The enhancement procedure proposed here is processed in the overlap region. R can be divided into four parts:

$$\begin{cases} R_1 & y_k = y_{k-1} = 0 \\ R_2 & y_k = y_{k-1} = 1 \\ R_3 & y_k \neq y_{k-1}, \text{ surrounded by } R_1 \text{ or } R_2 \\ R_4 & y_k \neq y_{k-1}, \text{ surrounded by } R_1 \text{ and } R_2 \end{cases} \tag{4}$$

In these four parts, R_1 and R_2 represent confirmed background and foreground respectively; R_3 often represents holes in blob and noise in background; R_4 represents the region caused by shape difference between two frames.

In (2), the transition probability $\Pr(x_k \mid x_{k-1})$ of one pixel p is determined according to the region R. Pixels belong to R_1 or R_2 are definitely from background or foreground, the transition probabilities $\Pr(x_k = 0 \mid x_{k-1} = i)$ and $\Pr(x_k = 1 \mid x_{k-1} = i)$ are undoubtedly very high; pixels belong to R_3 are in a noise blob, the states will be changed or remained according to the surrounding region in a high

probability since the noise must be eliminated; pixels belong to R_4 are the shape difference between two frames, the states will be changed in a high probability.

The likelihood $\Pr(y_k \mid x_k)$ of one pixel p is determined according to the region R and "how deep" p is in the region. The observation of p in R_1 or R_2 is more likely to be the same with the state. The state of R_3 is determined by its surrounding region. The observation and state of p in R_4 will change simultaneously in a high probability. We assume the likelihood obeys the normal distribution of the distance from p to its nearest skeleton branch in the region.

Thus after the foreground detection, a foreground enhancement algorithm is proposed as follows:

Step1. Find the corresponding targets in two frames and acquire the overlap region R;

Step2. Enhance the pixels in R by calculating the posterior possibilities and use MAP to determine the state of the pixel.

For the first frame, the detection result is simply considered as the initial state. The foreground enhancement algorithm mentioned above can increase the quality of foreground detection and make the silhouettes of the targets more intact.

Experimental Results.

In this section, we compare three state-of-art algorithms (GMM [8], SOBS[13] and ViBe [15, 16]) with our algorithm in two difference video sequences (people in a shopping mall and pedestrians in a building). The two video sequences represent two typical circumstances respectively: a few people in scene and large amount of people. Some frames of the two video sequences and the foreground detection results using four algorithms are shown in Table 1 and Table 2, respectively.

Table 1 Foreground detection results (People in a shopping mall)

Original frame	
GMM	
SOBS	
ViBe	
Our algorithm	

Table 2 Foreground detection results (Pedestrians in a building)

Original frame	
GMM	
SOBS	
ViBe	
Our algorithm	

The frames in each table are chosen randomly. Compared with ViBe, SOBS and GMM, the proposed algorithm can describe foreground much more accurate since the HMM are used, however, since the observation of HMM is obtained by using ViBe, the results in illumination variation occasions are worse than those obtained by using GMM.

Conclusion and Discussion

In this paper a foreground enhancement algorithm based on HMM has been proposed. The corresponding targets in successive frames is modeled using HMM, the observation of HMM is acquired by ViBe (other effective algorithm can also be used), the detection results are then be enhanced by calculating the probability of being foreground or background of each pixel, then use MAP to determine the final state of the pixel. Experimental results have proved the effectiveness of proposed method.

Keywords: Image registration, dimensional wavelet transform, cross power spectrum.

Abstract. We put forward a fast and efficiently sub-pixel registration method for solving the classical methods' problems of low efficiency, and use efficiently sub-images instead of original image to sub-pixel registration based on the Fourier transform phase correlation and matrix Fourier transform method. Effective sub-images are selected from the total size of the high-frequency energy after two-dimensional wavelet decomposition, then we use the phase correlation to calculate the pixel displacement and matrix Fourier transform to calculate the sub-pixel displacement. Not only the improved method is inherited the advantage of matrix Fourier transform sub-pixel registration, but also the registration speed is greatly improved. This is more applicable to massive remote sensing data. Through simulation and engineering practice, composited registration accuracy and speed, proved that the improved method is more efficient compared with the classical methods, and it's more suitable for real remote sensing image registration.

Introduction

With the rapid development of remote sensing technology, the technology of access to remote sensing data gradually incline to three multiples and three highs age with multiple platforms, multiple sensors, multi-angle and high time resolution, high spatial resolution, high spectral resolution[1]. Therefore, the amount of information for aerospace remote sensing data obtained increases exponentially [2], the magnitude of the remote sensing data obtained from high spatial resolution and high-precision surface information need efficient combination of theory with the hardware technology. The development of theory is often restricted by hardware technology updates. From hardware, The unit pixel size of CCD sensor can be limited access to shrink and expensive, which restricts the spatial resolution remote sensing image. By using one or more of the same scene in recent years, the low resolution of remote sensing image can be become a high resolution remote sensing image by the super-resolution reconstruction, which has become a research hotspot, and the subpixel registration accuracy of low resolution image and efficiency in image reconstruction process is particularly important

Subpixel image registration algorithm mainly include interpolation[3], extension of phase correlation [4] and settlement optimization problem [5-7]. Interpolation performance is affected by interpolation algorithm. Although accuracy of solving optimization problem is high, but the amount of calculation in the practical application is very large [8]. And the phase correlation method can integrate the performance of above two methods, which includes phase correlation in airspace and phase correlation in the frequency domain. Frequency domain phase correlation method is put forward by Kuglin [9] in parameter to solve the image translation at the earliest, the registration accuracy can reach pixel level. Alliney [10] and others use Fourier-Mellin transform to extends image registration to different conditions, such as rotation, translation, scaling and involved are pixel registration; and then Soummer [11] put forward the matrix multiplication Fourier transform which is used to image the subpixel registration, the method is based on phase correlation matching pixel level, and sample to the discrete Fourier transform after obtained the integral displacement field of a certain

range, the registration accuracy is better by comparing with traditional subpixel registration method [12]. Because the method has a calculation process of the phase correlation pixel displacement, when amounts of data is large, the amount calculated is larger, so this method is not very practical for the vast amounts of remote sensing data. The translation of image is a whole process, the translation of the whole image can represent the translation of the local area of the whole image, and partial translation information can reflect changes of the whole image translation.

An improved sub-pixel registration method is proposed for remote-sensing image, which use wavelet transform to select local effective subgraph to replace the original image, and use Fourier transform to calculate the matrix multiplication subpixel level displacement, so that through effective subgraph alternative to reduce the amount of calculation and improve the efficiency of registration. Effect of some existing method[13] is better in solving to match images of transformation on time with rotation, distortion and so on, but the essence of which is not in order to improve the accuracy and efficiency of registration, this improved method only consider a translational transform image registration.

In order to improve the registration efficiency, using effective subgraph instead of the original image to subpixel registration can greatly shorten the amount of calculation of the registration process. Compared with the traditional method, this method can satisfy the requirement of subpixel registration accuracy which can exponentially improve registration efficiency at the same time, and is suitable for remote sensing image registration of huge amounts of data.

Simulation experiment

Computing platform is a notebook computer with 4 GB RAM, Intel Core-i3 and 1.8 GHz CPU, The calculation software is Matlab7.0. The selected image is a Lena image with size of 512 × 512(Figure 2a). The image with sub-pixel displacement of $\triangle_1$(10.4857, 10.4857) in the experiment is shown in Figure 2b, Subpixel displacement image is realized by the Fourier transform phase displacement.

(a) The reference image (b) The image registration

Fig.1 Experimental images

We segment the image into 16 uniform sub-images, The size of each sub-image is 128×128, We use two-dimensional wavelet to each sub-images decomposition, when the sum of three decomposed high frequency component is maximum, the sub-images are effective sub-images.

The selection results of effective sub-images are shown in Figure 2a and 2b, such as the highlighted sub-block, Figure 2c is a magnified image of the highlight in Figure 2a, Figure 2d is a magnified image of the highlight in Figure 2b.

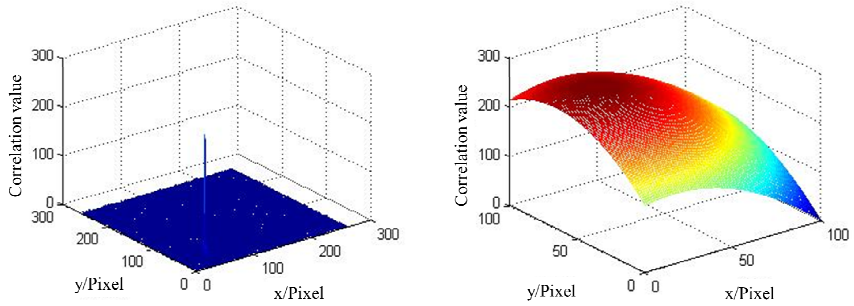
Fig.2 Effective sub-images

The up-sample ratio k is set 100, and then we respectively use the WPM algorithm, the methods of Reference [9] and [12] to registration of effective sub-images Figure 2 c and 2d, the registration results are shown in Table 1. Coarse registration of normalized phase correlation method at pixel level by the WPM algorithm in the process of registration and spectrogram of matrix multiplication DFT subpixel level registration are respectively shown in Figure 3a and 3b,

Tab.1 The comparison of accuracy and speed between different methods

Registration parameters / Registration method	The X direction displacement/pixel	The Y direction displacement/pixel	Registration time/second
The standard displacement Δ_1	10.4857	13.7384	
WPM algorithm	10.49	13.74	0.244
Algorithm of Reference[9]	10	14	0.014
Algorithm of Reference[12]	10.49	13.74	0.465



(a) Pixel registration (b) Subpixel level registration

Fig.3 The power spectrum of the image

Comparing with phase correlation method of the Reference [9], registration precision of WPM algorithm can reach 0.01 sub-pixel accuracy (from Table 1),which can well meet the requirements of sub-pixel registration, and comparing with the up-sample matrix multiplication DFT algorithm of the Reference [12]. When registration precision meet the requirements, computing time of WPM algorithm shorten half, and whole efficiency nearly doubled. The corresponding extreme value point of the coarse positioning and fine positioning has uniqueness by power spectrum diagram, which can be obtained corresponding image displacement accurately. Simulation experiments show that WPM algorithm can satisfy the sub-pixel registration precision and registration efficiency is very high, which can be well applied to engineering practice.

Summary

This paper puts forward a improvement registration method of effective subg-image instead of the original image, At the high-precision sub-pixel registration accuracy between images, the registration speed increases, the computational burden of the registration process reduce, which is suitable for remote sensing data processing. The innovation points are as follows in this paper: (1) We select effective subg-images instead of the original image in sub-pixel registration, the amount of calculation greatly reduce and the registration efficiency are greatly improved in the actual mass data of remote sensing image processing. (2) We use effective sub-images for registration phase correlation algorithm to obtain image pixel level displacement, and then use the up-sample matrix multiplication discrete Fourier transform to calculate displacement at pixel level for sub-pixel registration, the amount of calculation of improved algorithm combining the two steps is twice reduced. At improving efficiency, we ensure the sub-pixel registration accuracy,which can be widely used in remote sensing image processing.

The Study of Combination Filtering for Removing Mixed Noise of Remote Sensing Image

Cui Zhou[1,2,a], Jinghong Zhou[2] and Donghao Fan[2]

[1]College of Traffic Information, Hunan Communication Polytechnic, Changsha Hunan 410132, China

[2] School of Geosciences and Info-physics, Central South University, Changsha Hunan 410083, China

[a]cuizhou@163.com

Keywords: Remote sensing image denoising, Combination filter, BayesShrink threshold, Adaptive median filter, Wiener filter, Gaussian noise, Impulse noise.

Abstract. The traditional combination filter method in the practical process is often two layers of composite filtering de-noising for the image containing the gaussian mixture noise and pulse noise. This paper proposes a three filter combination algorithm based on the two layers filters, To the Gaussian and pulse mixed noise of the remote sensing image, we use wavelet threshold de-nosing and adaptive median filter de-nosing, and then using the third layer adaptive Wiener filtering de-noising to remove the residual noise. Through theoretical analysis and practical application, the de-nosing results of this method is obvious in processing mixed noise of remote sensing image, this is a practical method of combination filtering de-noising, it can be widely used in the field of image processing.

Introduction

Remote sensing images are affected by noise pollution in the process of acquisition, transmission, etc, which lead the quality of the images to drop and affect the visual effect of image and data quality. The median filtering, average filtering, wavelet denoising and so on are main image denoising methods. Wang L.[1] has different improved median filtering methods based on the basis of the traditional median filter. Xing Z. [2] proposed a more windows median filtering method to overcome the disadvantage of separation of conventional adaptive median filtering between the image noise and median filtering process. Comparing with the traditional median filtering, these methods have obvious advantage. The wavelet threshold denoising algorithm is firstly proposed by Donoho [3], that is common Wavelet-Shrinkage algorithm. At the same time, Donoho [4] puts forward a VisuShrink method to compute the threshold, removal effect is obvious for Gaussian noise. Gonglin Gao [5] denoise for different image based on stationary wavelet transform method, due to reduced sampling which reduces the image edge information of the process, it is better than the wavelet transform. The above methods are all single filter methods, the limitations will appear in the face of a single the mixed noise. Therefore Wencheng Yuan [6] put forward a combination method of median filtering and adaptive Wiener filtering method, comparing the single filter method, it is more practical in actual situation contains the mixed noise such as Gaussian, pulse image. Hui Yang [7] used combination filtering method of adaptive median filtering and adaptive Bayes Shrink wavelet domain threshold filtering for image noise mixed processing, but the filtering process cause a certain degree of edge data smoothing and the resolution of the image is reduced. YouFu Wu [8] use a combination method of stationary wavelet and median filtering combined filtering approach to remove mixing noise, and the filter process is all the pixels in noise image, the process of non-noise pixel is the filter and introduces excess noise pollution.

By summing up the above single filtering de-noising characteristics and combination filtering denoising method, most combination filtering methods are available to two layer containing mixed noise of image filtering de-noising, denoising effect is not complete. In order to solve this problem, this paper put forward a kind of the combination of the three layers filter of denoising filtering

method, the algorithm firstly remove gaussian noise of the image based on the two-dimensional adaptive stationary wavelet transform BayesShrink threshold, and use the Gauss-Laplace operator to extract image edge after denoising. Then we take adaptive median filtering process for the rest of the image edge after extraction based on the number of judgment of impulse noise, and eliminate the pulse noise of image. And then we will use adaptive Wiener filter to smooth the image; Finally we will blend smoothed image and extracted edge.

Simulation and experiments

In order to verify effectiveness and superiority of the improved three-layer filter of the image denoising method, Lenna grayscale image size is set as 256 × 256 in the simulation experiment, we compared the experiment according to common hybrid noise in remote sensing image with different combination filtering method. The common mixed noise of remote sensing image mainly contains four types: 0.01/0.0005, 0.02/0.001, 0.05/0.001, 0.02/0.001, The former of the two data of each type data represents variance of the Gaussian noise, and the latter represents the density of impulse noise. Compared with the combination filtering methodreferences of [6], [7], [8], [9], [10], the combination of improved filtering method was carried out. The image denoising effect was quantitatively analyzed and compared by the peak signal-to-noise ratio (PSNR) and mean square error (MSE). Formulas of PSNR [11] and MSE [12] respectively type such as Eq. (1) and Eq. (2). The bigger PSNR values represents the better denoising effect, and the smaller MSE value represents the better denoising effect.

$$PSNR = 10\lg\frac{(M \times N)}{(f - \hat{f})^2} \tag{1}$$

$$MSE = \frac{1}{M \times N}\sum_{i=1}^{M}\sum_{j=1}^{N}[f(i,j) - \hat{f}(i,j)]^2 \tag{2}$$

Taking the 0.01/0.0005 mixed noise type as an example, the image mixed by Gaussian and impulse noise and the denoising image improved by combination filtering method in this paper were obtained, respectively, these images are shown in Figure 1. The removal effect of the different types of mixed noise by various combination filtering methods is shown in Table 1. According to Table 1.

The improved combination filter method in removing image of gauss noise and pulse mixing has better denoising effect than the combination of the traditional filtering method. From Table 1, when the image contains hybrid noise is smaller in each method, the denoising effect is better than that of bigger one, so the denoising effects are still affected by the amount of noise. Comparison in Table 1 shows target of the PSNR, the improved method is higher than the method of Ref. [9] a small amount of value. As shown in Figure 1, The denoising results of the method of Ref. [9] and improve the filtering method for the 0.1/0.01 type shows noise amplification, denoising effect is superior to the method of Ref. [9] from the contrast method. Comprehensive comparing the indicators, peak signal to noise ratio of improved filtering method is maximum and mean square error is minimum, the denoising effect is superior to traditional methods, which has obvious advantages in the visual effect of qualitative and quantitative analysis of data, and particularly suitable for remote sensing image which contains mixed noise removal.

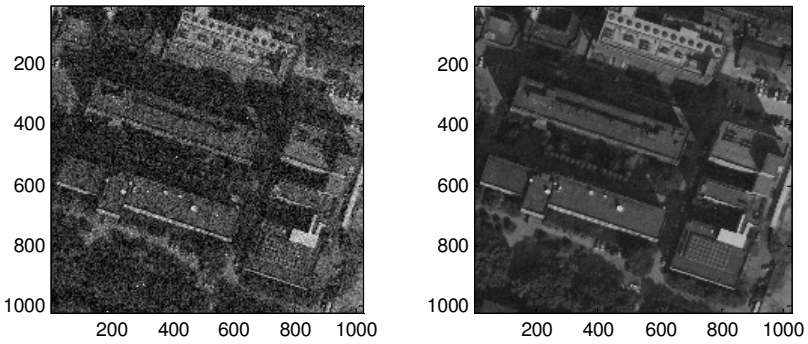
Engineering applications

In order to further illustrate the improved combination filtering method applied to the actual remote sensing image denoising effect, we conducted a set of experiments for the actual remote sensing image. The experimental images cut out from the skies over an area of remote sensing images, the image size is 1024 × 1024. Taking the 0.01/0.0005 mixed noise type as an example, the image after mixed with Gaussian and impulse noise is shown in Fig. 2a and the images after denoising with the improved composite filter method is shown in Fig. 2b, we respectively use four common types in remote sensing image mixed with pulsed Gaussian noise experiment. The mixed types of noise is as follows：0.01/0.0005, 0.02/0.001, 0.05/0.001, 0.1/0.01.



(a) The image mixed noise pollution (b) The denoising image by improved method

Fig.2 The effects of this method to remove mixed noise

Summary

Comparing with common filtering method, this method has obvious advantages in the human eye visual effect and the data quality of denoising: (1) The remote sensing image mixed noise removal is proposed by using the three layer filter method. The traditional methods are combination denoising of two layers for image with Gaussian and impulse noise denoising, although which has certain effect, but it is not sufficient because without taking into account the two layers of filter denoising. (2) This method is a new type of composite filtering denoising method. To greatest degree protection of useful information of the image, this new method can effectively remove common in remote sensing image with Gaussian mixture noise and pulse, and fully retained the image edge details, especially suitable for common types of mixed noise removing remote sensing images, which can be applied in practical applications.

Keywords: Hyperspectral image classification, Sparse Representation, Dictionary Learning, Local Binary Patterns.

Abstract. Hyperspectral images (HSI) have rich texture information, so combining texture information and image spectral information can improve the recognition accuracy. Sparse representation has significant success in image classification. In this paper, we propose a new discriminative sparse-based classification framework using spectral data and extended Local Binary Patterns (LBP) texture. Firstly, we propose an extended LBP coding for HSI classification. Then we formulate an optimization problem that combines the objective function of classification with the representation error by sparsity. Furthermore, we use a procedure similar to K-SVD algorithm to learn the discriminative dictionary. The experimental results show that the proposed discriminative spasity-based classification of image including the extended LBP texture outperforms the classical HSI classification algorithms.

Introduction

Hyperspectral imaging technique is a great leap in the remote sensing techniques. The remote sensors capture digital images in hundreds of narrow spectral bands spanning the visible to infrared spectrum [1]. HSI has been found many applications in various fields, and the base one is HSI classification. However, the traditional HSI classification algorithms for will result in low classification precision and data redundancy. It is necessary to find an effective HSI classification algorithm. The high resolution HSI has rich space structure information [7]. Thus, combining texture information and image spectral information in HSI classification can improve the recognition accuracy.

In recent years, sparse-based techniques have a lot of successful applications in compute vision and image processing fields [2-6]. These applications are mainly based on the observation that the images in the same class usually lie in a low-dimensional subspace.

Considering the characteristic of HSI and the limitation of traditional classification techniques, based on sparse representation and LBP texture, a new effective HSI classification framework is proposed. Firstly, an extended LBP coding for HSI is proposed, and the LBP image and the original HSI are fused to obtain the fused HSI for classification. Then an discriminative optimization problem is formulated. Furthermore, we use a procedure similar to K-SVD algorithm to learn the discriminative dictionary.

Classification based-on Discriminative Sparse Representation and Extended LBP

Local Binary Patterns and the Extended LBP for HSI

The original LBP operator [7] is a powerful illumination invariant texture primitive. The operator describes each pixels of an image by the relative graylevels of its neighboring pixels. Then the histogram of the binary patterns computed over a region can be used as a texture descriptor.

However, in HSI, each pixel forms a spectral vector, we should analyse the LBP of every band image. This would result in low efficiency and poor effects. So we extend LBP for HSI by measuring it with the relation among spectral vectors instead of graylevel. The extended LBP defined as Eq. 1,

$$LBP_{P,R}(x,y)=\sum_{p=0}^{P}s(v_c,v_p)2^p,\quad s(v_c,v_p)=\begin{cases}1, & corr(v_c,v_p)>K\\ 0, & otherwise\end{cases}. \tag{1}$$

Where, v_c and v_p denote the spectral vector of the center pixel and P equally spaced pixels on a circle of radius R respectively. K is the threshold, and $corr\left(v_c, v_p\right)$ is the correlation coefficient of v_c and v_p.

Finally, the obtained LBP image is added to the original HSI as an extra band image. Then, the new HSI is used for the sparsity-based classification.

Discriminative Sparse Representation

The SRC algorithm assumed that the training samples of a particular class approximately form a linear basis set for any test sample belonging to the same class. However, the reconstructive dictionary in SRC is not the best for the classification problem. The training samples selected manually may not span the reasonable underlying subspace. Then, K-SVD algorithm which learns an over-complete dictionary with a fixed number k of atoms is proposed by solving the following minimization problem,

$$\min_{\alpha, D} \sum_{i=1}^{n} \left\| a_i - D\alpha \right\|_2^2 \quad \text{s.t. } \left\| \alpha_i \right\|_0 \le L. \tag{2}$$

But these dictionaries without discriminative power may not be optimal for a classification task. The main goal of our method is to learn discriminative dictionaries and not only reconstructive ones.

Thus, we design a discrimination function by the classical linear discriminant analysis

$$f(\bullet) = \frac{trace(S_b)}{trace(S_w) + \mu}. \tag{3}$$

Where S_b and S_w are the standard between-class and within-class scatter matrices, and μ is a regularization parameter. Then, we obtain the final objective function Eq. 4 is obtained by incorporating the discrimination function Eq. 3 into the objective function Eq. 2.

$$\min_{D, \alpha} \left\{ \sum_{j=1}^{c} \sum_{i=1}^{n_j} \left\| a_i^j - D\alpha_i^j \right\|_2^2 - \lambda \cdot f\left(\left\{ \left\{ \alpha_i^j \right\}_{i=1}^{n_j} \right\}_{j=1}^{c} \right) \right\}. \tag{4}$$

Discriminative Sparsity-based Classification

In order to achieve the classification goal, we try to seek the internal structure within each class and at the same time global discrimination among the classes. Now we optimize the dictionary that is reconstructive and discriminative, we rewrite the Eq. 4 as Eq.5,

$$\max_{D, \alpha} \left\{ \lambda \cdot f\left(\left\{ \left\{ \alpha_i^j \right\}_{i=1}^{n_j} \right\}_{j=1}^{c} \right) - \sum_{j=1}^{c} \sum_{i=1}^{n_j} \left\| a_i^j - D\alpha_i^j \right\|_2^2 \right\} \tag{5}$$

To solve the optimization problem, we extend K-SVD by instead the classical OMP of another better one improved from SOMP in the sparse coding stage. The whole process is shown as follows.

Initialization: Initialize $J = 0$, and

- Initialize dictionary: $D_{(0)} \in R^{B \times n}$, hyperspectral pixels $\left\{ \left\{ a_i^j \right\}_{i=1}^{n_j} \right\}_{j=1}^{c}$, sparsity level L
- Normalization: Normalize the columns of $D_{(0)}$

Main Iteration: Increment J by 1, and apply

- Sparse coding stage: Use the following procedure to compute the sparse coefficients $\left\{ \left\{ \alpha_i^j \right\}_{i=1}^{n_j} \right\}_{j=1}^{c}$ for each hyperspectral data $\left\{ \left\{ a_i^j \right\}_{i=1}^{n_j} \right\}_{j=1}^{c}$.

  Step 1: Set the class counter $q = 1$ and $\Gamma_0 = \varnothing$

  Step 2: Selection of L vectors according to the structure of the class q

  2-1. Initialize the residuals $r_i^{j(0)} = a_i^j$, the index set $\Lambda_0^q = \varnothing$, iteration counter $t = 1$

  2-2. Find the index ϑ_t^q by solving $\vartheta_t^q = \arg\max_{p=1,\ldots,n} \left\{ \sum_{i=1}^{n_q} \left| \left\langle r_i^{q,(t-1)}, d_p \right\rangle \right| + \lambda \cdot f\left(\left\{ \left\{ \left\langle r_i^{j,(t-1)}, d_p \right\rangle \right\}_{i=1}^{n_j} \right\}_{j=1}^{c} \right) \right\}$

2-3. Set $\Lambda_t^q = \Lambda_{t-1}^q \cup \{\vartheta_t^q\}, \Phi_t^q = \left[\Phi_t^q, d_{\vartheta_t^q}\right]$.

2-4. Calculate new coefficients and residuals $\alpha_i^{j,(t)} = \left(\Phi_t^{q'}\Phi_t^q\right)^{-1}\Phi_t^{q'}a_i^j, r_i^{j,(t)} = a_i^j - \Phi_t^q \cdot \alpha_i^{j,(t)}$

2-5. Set $t = t+1$. If $t \le L$, go to 2-2, else go to step 3.

Step 3: Save the estimates $\tilde{a}_i^{q,(L)}$ for class q, and its coefficients $\alpha_i^{q,(L)}$

Step 4: $\Gamma_q = \Gamma_{q-1} \cup \Lambda_L^q, q = q+1$. If $q < c$ go to step 2, else return.

- Dictionary update stage: Use the following procedure to update the columns of the dictionary and obtain $D_{(J)}$: repeat for $j_0 = 1,2,...,n$
  - Define the group of examples that use the atom d_{j_0}, $\Omega_{j_0} = \{i \mid 1 \le i \le n, d_j^{j_0}(i) \ne 0\}$
  - Compute the residual matrix $\mathrm{E}_{j_0} = a - \sum_{j \ne j_0} d_j a'_j$.
  - Restrict E_{j_0} by choosing only the columns corresponding to Ω_{j_0}, and obtain $\mathrm{E}_{j_0}^R$.
  - Apply SVD decomposition $\mathrm{E}_{j_0}^R = \mathrm{U}\Delta\mathrm{V}'$. Update $d_{j_0} = \mathrm{u}_1$, and $\alpha_{j_0}^R = \Delta[1,1] \cdot \mathrm{v}_1$
- Repeat until convergence.

Finally, we design a method to determine the class. For the samples in class i, we design an indicator operator $\delta_i(\bullet)$, which can keep the coefficients corresponding to class i and set all others to be zero. Then the residuals by each class are compute, and the class of the test sample is determined by the minimal residual.

Experimental Results and Analysis

In this section, we performed extensive experiments on a well known hyperspectral dataset AVIRIS Indian Pines image to evaluate the effectiveness of the proposed approach. We use 6 classes which have sufficient training samples in our experiment. The pseudo color image from the Geographic Information System (GIS) image is shown in Fig. 1(a) and Fig. 1(b). We compared our results with classical methods i.e. parallelepiped classifier (PPC), spectral angle mapper (SAM), maximum likelihood classifier (MLC), BP neural network (BPNN) and SRC without LBP.

The visual classification results obtained by different classifiers are shown in Fig. 1(c)~(h). It's easy to see that, our proposed algorithm got better performance than other methods mentioned above.

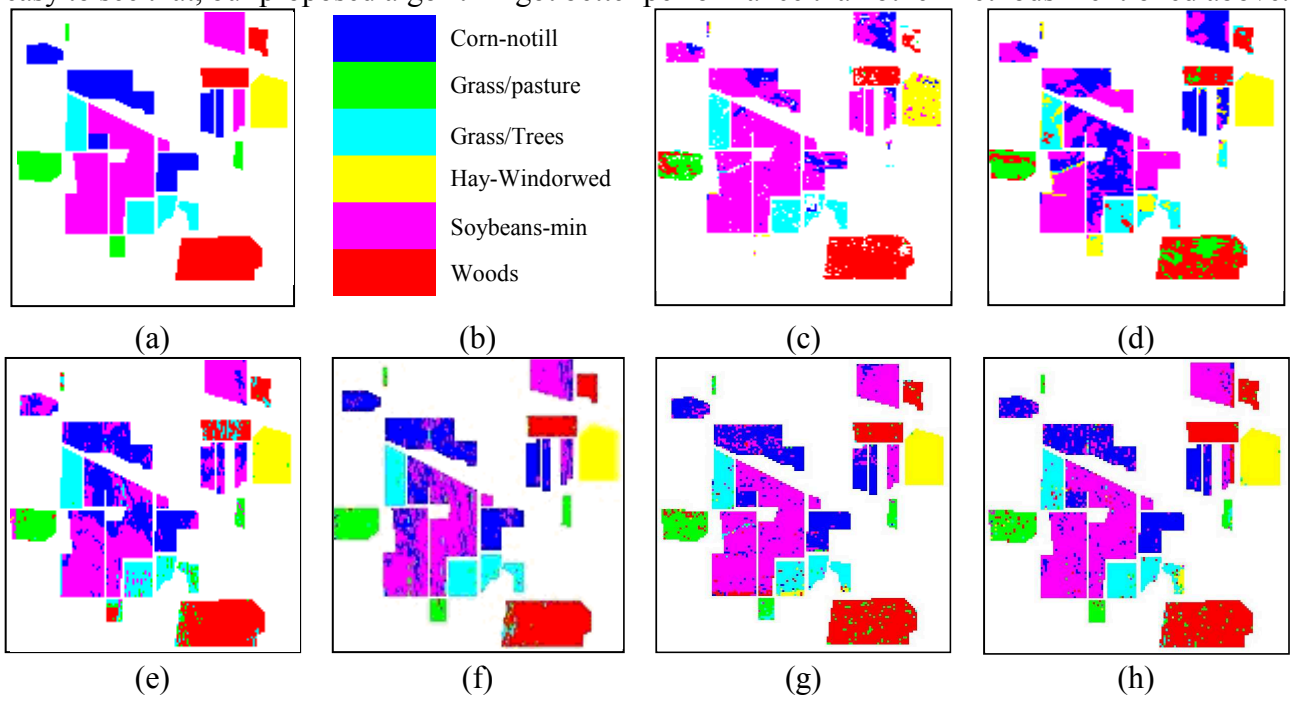

Fig. 1 The classification maps obtained by different classification methods. (a) The pseudo color image of the used 6 classes from the GIS image, (b) color map, (c) PPC, (d) SAM, (e) MLC, (f) BPNN, (g) SRC without LBP,(h) the proposed method

The classification accuracy for each class, the overall accuracy and the kappa coefficient are shown in Table 1. We can see that our proposed HSI classification algorithm competes against the others in either overall accuracy or kappa coefficient. That is because the proposed approach uses the rich texture information by the extended LBP image to improve the classification performance. Moreover, it uses the learned discriminative dictionary, not the reconstructive one.

Table 1. Classification accuracy (%) and kappa coefficient of these methods

Class	PPC	SAM	MLA	BPNN	SRC without LBP	Proposed method

Conclusions

In this paper, we have proposed an extended LBP coding for Hyperspectral images and added it to the original HSI as an extra band image. Furthermore, we proposed a new effective and discriminative sparse representation classification algorithm for HSI. In the proposed algorithm, we formulate an optimization problem that combines the objective function of classification with the representation error by sparsity, and use an improved K-SVD algorithm to learn the dictionary. The experimental results show that the proposed approch outperforms the classical HSI classification algorithms and the sparsity-based method without LBP image.

Keywords: Cognitive radio networks; QoS; Markov chain; channel reservation.

Abstract. In cognitive radio networks (CRNs), improving the performance of SUs is the main aspect of present study. In this paper, we focus on the optimal access strategy to provide QoS guarantees for multi-services. The contribution of this paper is as follows. Firstly, we formulate and solve the optimal spectrum access problem with different channel reservation scheme. Secondly, we take account of buffer for handoff secondary users and propose a handoff scheme for multi-services. In addition, the computation complexity of solving the optimal channel reservation problem is simplified by a binary search. The system is analyzed using a continuous-time Markov chain model. The numerical results confirm the validity of the proposed scheme.

Introduction

In recent years, with the rapid development of wireless technology, spectrum resource is becoming more and more intense. One important reason is that the traditional static spectrum allocation has led to low utilization of the spectrum, as it is presented in [1]. In this case, the concept of Cognitive Radio Networks (CRNs) has been proposed to improve the spectrum efficiency. In spite of the fact that the cognitive radio technology can effectively address the scarce of spectrum [2] [3], however, due to the unpredictability of the dynamically changing network resources, it is a great challenge to guarantee the quality of service (QoS) of CRNs requirements.

To improve the performances, many models and algorithms have been proposed in CRNs these years (e.g. [4]-[9]). In [6], channel reservation has been proposed to reserve several channels only for handoff secondary users (SUs). In [7], the case of sub-channel reservation for high-priority SUs with buffer for handoff SUs has been investigated, nevertheless, the problem has not been solved. The authors in [8] proposed a framework to analyze call admission control for performance improvement. In order to reduce the dropping probability, [9] has proposed a channel reservation scheme for the primary system, it shows that how to compute the optimum number of reserved channels.

In this paper, we focus on the optimal access strategy to provide QoS guarantee for multi-services. Different from the existing models, the QoS guarantee for multiple services is considered in an overlay centralized cognitive radio network. We propose a channel reservation scheme for multi-services' QoS guarantee of SUs. We establish a multi-dimensional continuous-time Markov chain to calculate the steady-state probability. Then, we analyze the performance of the system. In addition, the computation complexity of solving the optimal channel reservation problem is simplified by a binary search. Numerical results show that our proposed channel reservation scheme can provide the QoS guarantees of multi-services.

System Model

The cognitive radio system is composed of N channels. Since the PUs enjoy absolute priority on using licensed channel, one ongoing SU using the channel reclaimed by a PU should be handed off. The SUs are classified into three priority classes： SU_1, SU_2 and SU_3, corresponding to voice, video and data. Each channel can only accommodate one PU or SU, and r_1, r_2, r_3 channels are reserved for

new SU_1, SU_2, SU_3 calls respectively. The handoff buffer is only available for handoff SU_2 and SU_3 calls. We assume that there are N buffers to accommodate handoff SUs being suspended.

Call arrivals occur independently as Poisson processes with mean arrival rates of λ_p, λ_1, λ_2 and λ_3 for PU, SU_1, SU_2 and SU_3, respectively. The service times independently follow exponential distributions with mean service rates of μ_p, μ_1, μ_2 and μ_3 for corresponding services, respectively.

A new SU call is blocked when the number of idle channels is less than that of reserved channels. Whenever the handoff buffer is unempty, new SUs will be rejected. The SU calls in the buffer will be reassigned to the resulting idle channel according to their priorities when an ongoing call completes service. These reassigned SUs resume transmissions for their remaining service times. When a new PU call arrives, the CR system works as Fig.1.

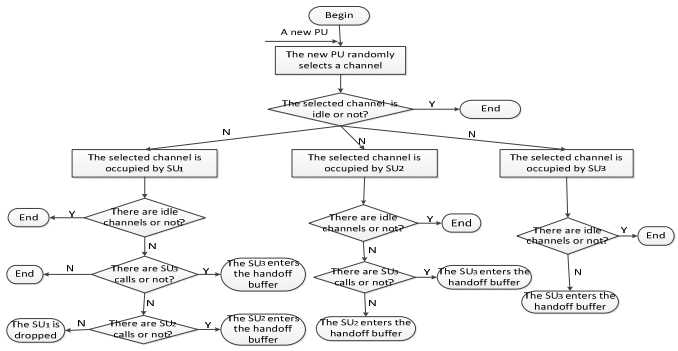

Fig.1. Flow chart of the system when a new PU arrives

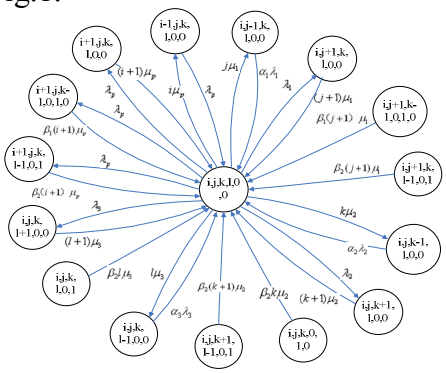

Fig.2. State transition graph when the buffer is empty

For this system, the state is denoted as $[i, j, k, l, k_q, l_q]$, where $i \in \{0,1,...,N\}$, $j \in \{0,1,...,N\text{-}r_1\}$, $k \in \{0,1,...,N\text{-}r_2\}$, $l \in \{0,1,...,N\text{-}r_3\}$ represents the number of ongoing PU, SU_1, SU_2 and SU_3 calls, respectively. And variables $k_q \in \{0,1,...,N\text{-}r_2\}$, $l_q \in \{0,1,...,N\text{-}r_3\}$ represent the number of SU_2 and SU_3 calls waiting in the buffer.

Fig.2 shows the state transitions graph when the buffer is empty. Specially, when $i+j=N$ and $j>0$ in current state, one of SU_1 calls will be dropped if a new PU arrives. Fig. 3 and Fig. 4 show the case that there are no ongoing SU_3 calls and there are ongoing SU_3 calls, respectively.

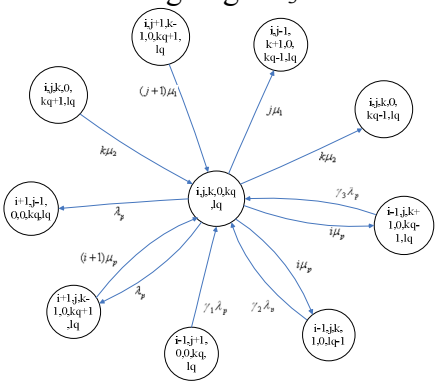

Fig.3. State transition graph when there are no SU3 calls

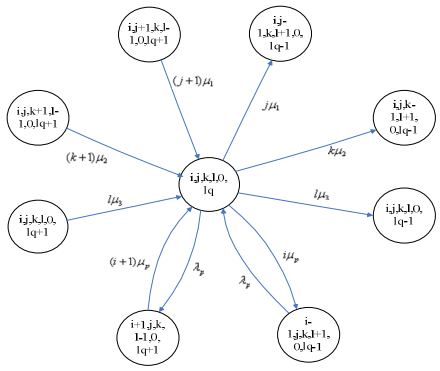

Fig.4. State transition graph when there are ongoing SU_3 calls

Performance Analysis

Let Y $(=i+j+k+l)$ denote the total number of busy channels at a given time instant. We can get the steady-state probability P_Z $(Z=[i, j, k, l, k_q, l_q])$according to the state transition graph. With the steady-state probability, we can derive the following performance measures.

1) The blocking probability.

$$p_{block(m)} = \sum_{\forall Z, Y \geq N - r_{(m)}} P_Z (m = 1,\ 2\ or\ 3). \tag{1}$$

2) The dropping probability.

$$p_{drop1} = \frac{\sum \lambda_p \cdot P_z}{\lambda_1 \cdot (1 - p_{block(1)})}. \quad (2)$$

3) Successful call completion rate. Successful call completion rate means without being blocked and dropped .The successful call completion rate of SU_1 , SU_2 and SU_3 is expressed as

$$R_1 = \lambda_1 \cdot (1 - p_{block1}) \cdot (1 - p_{drop1}). \quad (3)$$

$$R_{(s)} = \lambda_s \cdot (1 - p_{block(s)}) \ (s = 2 \ or \ 3). \quad (4)$$

The normalized successful call completion rate of SU calls denoted as R. ξ_1, ξ_2 and ξ_3 is the weight of the call completion rate of SU_1, SU_2 and SU_3, respectively. Then, R is expressed as

$$R = \xi_1 \cdot R_1 + \xi_2 \cdot R_{(2)} + \xi_3 \cdot R_{(3)}. \quad (5)$$

4) The mean handoff delay: the mean handoff delay for SU_2 (SU_3) calls is defined as the mean time taken by the SU_2 (SU_3) calls to perform successful handoff.

$$HD_2 = \frac{\sum_{\forall z, Y=N, l=0, k>0} P_z}{\sum_{\forall z, Y<N} \frac{k}{N-i} P_z + \sum_{\forall Z, Y=N, l=0, k>0} P_Z + \sum_{\forall z, Y=N, l>0} \frac{k}{N-i} P_z} \cdot \frac{\sum_{\forall z} k_q \cdot P_z}{\sum_{\forall z, Y=N, l=0, k>0} \lambda_p \cdot P_z}. \quad (6)$$

$$HD_3 = \frac{\sum_{\forall z, Y=N, l>0} P_z}{\sum_{\forall z, Y<N} \frac{l}{N-i} P_z + \sum_{\forall z, Y=N, l>0} P_z} \cdot \frac{\sum_{\forall z} l_q \cdot P_z}{\sum_{\forall z, Y=N, l>0} \lambda_p \cdot P_z}. \quad (7)$$

Results and Discussion

In this section, we evaluate the performance of this model. The accuracy of the analysis is verified through simulations. In our experiments, we use the following parameter settings: N=5, λ_1={0.6,0.8}, λ_2=0.8, λ_3=1, λ_p={0.1,0.2,...,1.1}, μ_1=0.6, μ_2=0.8, μ_3=0.8, μ_p=1.2, $r_1 \in$ {0,1,...,5}, $r_2 \in$ {0,1,...,5}, $r_3 \in$ {0,1,...,5}.

We assume the QoS threshold of dropping probability of SU_1, ς_1, is 0.01, and the QoS threshold of the mean handoff delay of SU_2, ς_2, is 0.025. Meanwhile, due to the priority, the weights of multi-services for normalized call completion rate of SU calls is reasonable to be set as ξ_1=0.45, ξ_2=0.4, ξ_3=0.15. For convenience, symbols<a>and<s>in the figures indicate analytical and simulation results, respectively.

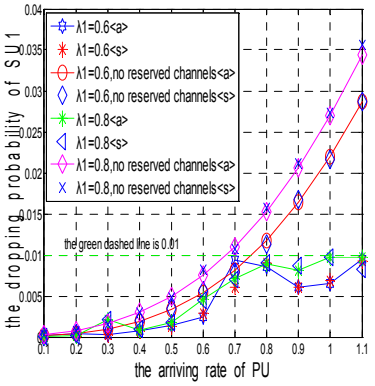

Fig.5.The arriving rate of PU vs. CDP of SU_1

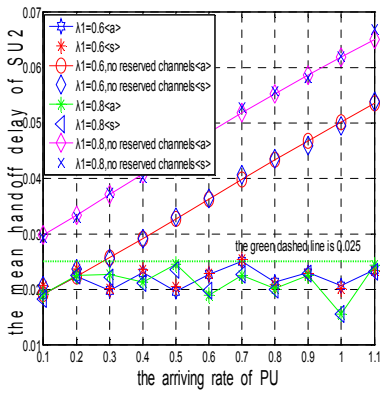

Fig.6.The arriving rate of PU vs. HD of SU_2

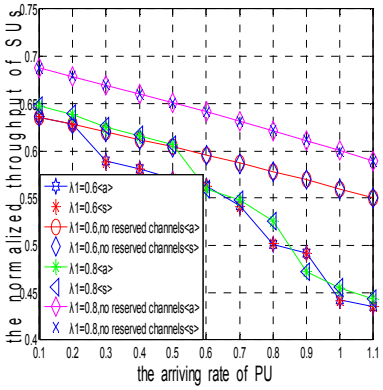

Fig.7.The arriving rate of PU vs. NT of Sus

Fig. 5 and Fig. 6 show the impact of the arriving rate of PU on the dropping probability of the SU_1 and the mean handoff delay of SU_2. By comparison, we present the results for the case that no channel reservation action is taken as well. As we know, when the traffic of PUs is low, the QoS of

SUs can be met, hence the traffic control is not necessary, as shown in Fig.5 and 6 when λ_1=0.6 and $\lambda_p \leq 0.2$, the dropping probability as well as handoff delay are the same for both cases with no traffic control. With the increasing of PUs traffic load, the dropping probability and handoff delay will increase due to less channels available for SUs, the dropping probability is higher than the threshold value (i.e., 0.01) if there is no reserved channel. Nevertheless, by using our optimal channel reservation scheme, no matter how high the PUs' traffic load is, the dropping probability and handoff delay can always be maintained below the predefined threshold value as shown in Fig.5 and 6. And in the case of λ_1=0.8, we can get the same conclusion.

In Fig.7, we give the relationship between normalized throughput and arrival rate of PU. As expected, no matter λ_1=0.6 or λ_1=0.8, the normalized throughput decreases with the arriving rate increasing. When there are reserved channels, the normalized throughput is lower than that of the case of no reserved channels, as the cost of guarantee the QoS of multi-services of SUs.

Summary

In this paper, a multi-dimensions stochastic model is proposed to analyze the performance of an overlay cognitive radio network. We have considered three levels of prioritization in the SU traffic, and the reserved channels for different types of new SU are different, which make us enable to not only provide the QoS guarantees of multi-services. As for performance analysis, we derived blocking probability, dropping probability, mean call completion rate and mean handoff delay for SUs. In addition, the computation complexity of solving the optimal channel reservation problem is simplified by a binary search. The analytical results have been verified through simulations. In the future, we will study the impact of the imperfect channel sensing on the optimal channel reservation and more accurate admission control.

Keywords: Infrared image, exponential transform, dual threshold, detail enhancement,grayscale transform.

Abstract. Since the thermal imaging system detection ability and spatial resolution is lower than visible light CCD array,the definition of the infrared image is lower than that of the visible light image, which needs enhancement to improve image quality and for human vision. This paper proposes an enhancement algorithm of infrared images based on dual threshold of the exponential transform, firstly the original image can be processed by median filter to reduce noise,next separate the detail information of the 14-bit infrared image after noise reduction; then deal the detail image with the double threshold method based on the exponential transform,retaining or enhancing the detail information;when it comes to the base image,deal it with the gray linear mapping method, compressing its dynamic range.Finally the detail image and the base image are composed together after processing,getting 8-bit infrared image which can display and be processed on an ordinary display.

Introduction

Along with the increasingly mature of uncooled infrared detector, the application of thermal imaging technology is more and more widely in military and civilian areas.Infrared thermal imaging technology[1] is a image information detection technology based on heat radiation,which performances the heat radiation of the target surface in the form of image.However the characteristics of infrared image, device processing technic and environmental factors result in infrared image with low contrast,low resolution and low signal-to-noise ratio. In order to accurately identify the target in a infrared image and improve the quality of the infrared image, the image should be enhanced appropriately,highlighting some interested parts selectively,such as the target in the infrared scene and the tiny structure on its surface. In addition,the noise often appears in the infrared thermal imaging system.When enhancing the infrared image,the noise which often is mistaken for details in the image,will be enhanced together,which eventually led to the decline in image quality.

At the same time,the infrared image has the characteristic of high dynamic range.In order to quantify the high dynamic range infrared image with sufficient accuracy, imaging system generally uses 14 bits or higher bits analog-to-digital(A/D) converter in the output signal of the detector for analog-to-digital conversion.While the conventional display device can only support 8-bit image, so it is necessary to compress the infrared image with high dynamic range properly. However, choosing irrelevant compression can easily cause the loss of detail information in the compression process and result in non-ideal effect in 8-bit image after compressing . Aimed at single frame infrared image,this paper proposes a new enhancement algorithm of infrared image. Firstly the original image can be processed by median filter[2] to reduce noise，next separate the detail information of the 14-bit infrared image after noise reduction by using high-pass filtering[3],obtaining the detail image;at the same time,the original infrared image after noise reduction subtracts the detail image to get the base image;then deal the detail image with the double threshold method based on the exponential transform processing,retaining or enhancing the detail information;when it comes to the base

image ,deal it with the gray linear mapping method[4],compressing its dynamic range . Finally the detail image and the base image are composed together after processing, getting 8-bit infrared image.

Algorithm description

Noise reduction on original image.

After non-uniformity correction, the noise mainly performancing as random disturbance is the high frequency information[5] in the original infrared image. On account of the goal of the system is detail enhancement, which inevitably will lead to noise enhancement and the decline in image quality. There are many effective solutions for reducing noise, but they are usually limited with a large amount of calculations and their feasibility. As is shown in figure 1, the 14-bit original infrared image is captured by the infrared thermal imaging system which is independently researched by our laboratory. In view of the single frame infrared image captured, it is proper to deal it with median filter, which can not only remove isolated noise, but also keep the edge feature of target and make the image not significantly fuzzy. So we select a median filter with window size w * w(w is an odd); then we scan the infrared image with w * w window,sort the datas contained in the window and get the median as the grey value of central point in the window,thereby reducing noise in the image. The advantages of this method is simple and fast computing speed,besides the simulation results show it has better effect on noise elimination and loss less useful detail information.

Fig. 1 The original infrared image

The separation of detail image and base image .

As is shown in figure 3(a),the infrared image after noise reduction contains rich detail information and has low contrast in detail part,having a gray scale range from 768 to 9788,about 9000 grayscale. Compressing and enhancing the whole image directly result in the loss of detail information and merging gray level of detail information to the adjacent grey level.As a result,the infrared image after noise reduction should be firstly separated to detail image and base image,the detail image and base image should be enhanced and compressed respectively.

Owing to the high frequency characteristic of the infrared target,it is proper to get detail information of high frequency by using high-pass filter.So the Butterworth high-pass filter is a good choice.Then the original infrared image after noise reduction subtracts the detail image to get the information of base image. Ideal high-pass filter and Butterworth high-pass filter can get better filtering effect in several high-pass filters. But because the images we need mostly contain complex background information,so the obvious "ringing" phenomenon of ideal high-pass filter is bad for target detection.The "ringing" phenomenon of Butterworth high-pass filter is usually smaller in comparison with that of ideal high-pass filter.In addition, Butterworth high-pass filter has a flexible filtering property.So it is necessary to transform the infrared image to frequency domain first by using fourier transformation,next Butterworth high-pass filter processes the infrared image in frequency domain.To get the detail information of the image,we must do Fourier inverse transformation.Then we decompose the detail image and the base image for subsequent processing.

The n order Butterworth high-pass filter transfer function is defined as follows:

$$H(u,v)=\frac{1}{1+[D_0/D(u,v)]^{2n}} \tag{1}$$

Where the bigger the cut-off frequency D0 is set, the more the low-frequency component is filtered out, the more the high-frequency component losses; The cut-off frequency D0 must be set a proper value,which can not only filter out low frequency component, but also can retain most detail information of the detail image.

The detail enhancement of detail image and the gray-scale compression of base image.

Since we can get the detail image by the above steps, the original infrared image after noise reduction subtracts the detail image to get the information of base image.Then we adopt different methods to process the detail image and base image respectively.

On the one hand the infrared image which doesn't contain color information records the temperature information,and on the other hand temperature corresponds with the brightness of pixels. As is shown in figure 3(a),the infrared image can be regarded as 14-bit gray-level information. The grayscale of the 14-bit detail image isolated from figure 3(a) ranges from 1197 to 2049,which is much smaller than that of base image. So in order to expand gray of target region, compress gray of background and transition region,while the whole gray mapped to the range 0 ~ 255,it is reasonable to choose double threshold method based on the exponential transform to map grayscale.The function $P\{f^{detail}(i,j)\}$ can be expressed as follows:

$$P\{f^{detail}(i,j)\}=\begin{cases}\dfrac{f^{detail}(i,j)-\min)\times(f^{detail}(i,j)+1)^{\gamma}}{f_{mid1}-\min} & f^{detail}(i,j)<f_{mid1}\\ \dfrac{(f^{detail}(i,j)-f_{mid1})\times(f^{detail}(i,j)+1)^{\alpha}}{f_{mid2}-f_{mid1}} & f_{mid1}<f^{detail}(i,j)<f_{mid2}\\ \dfrac{(f^{detail}(i,j)-f_{mid2})\times(f^{detail}(i,j)+1)^{\gamma}}{\max-f_{mid2}} & f^{detail}(i,j)>f_{mid2}\end{cases} \tag{2}$$

In eqution 2, min represents the minimum of grayscale in the image,max represents the maximum of grayscale in the image.In figure 3(b),max=2049,min=1197. The two proper threshold values f_{mid1} and f_{mid2} are choosen for splitting image,we choose f_{mid1}=min+(max-min)/5, f_{mid2}=min+3(max-min)/5. The values of f_{mid1} and f_{mid2} can be adjusted according to the image.

Generally speaking, the grayscale of infrared target is located in the high-level of gray histogram, we consider that gray values of the pixels greater than the threshold value belong to the target, other pixels belong to the background and transition region. Adopt different parameter functions to the target, background and the transition region separately , extending the gray of target region, compressing the gray of background and the transition region.With regard to target region ,the parameter of the exponential transform function α should be selected greater than 0.To expand the grayscale of target region,we take α=0.7.For the background and transition region, the parameter of the exponential transform function γ should be taken less than 0;To compress the grayscale of these regions,we take γ=-0.9. In other case, it is also available to choose any other suitable values.

The gray scale of the 14-bit base image isolated from figure 3(a) ranges from 2351 to 8475,which contains high dynamic range grayscale. In the premise of not affecting the imaging quality, we choose the simple linear mapping[4] to achieve the gray compression of non-detail information, reducing calculation and improving the processing speed. The gray linear mapping equation is defined as following:

$$Q\{f^{base}(i,j)\}=\begin{cases}0 & f^{base}(i,j)\le\min\\ \dfrac{f^{base}(i,j)-\min}{\max-\min} & \min<f^{base}(i,j)<\max\\ 255 & f^{base}(i,j)\ge\max\end{cases} \tag{3}$$

First count up the gray histogram of base image H(k),k=0,1,2,3...L-1;L stands for the gray-scale number of the base image. Then count pixels from the two ends of the gray histogram to middle individually, S_1=H(1)+ H(2) +…+H(min),S_2=H(L-1)+H(L-2) + …+H(max) , where 0 < min<max<L.

Estimate the values of S_1 and S_2, stop accumulating S_1 and save the value of min when S_1>T; stop accumulating S_2 and save the value of max when S_2>T,in which T is the preset threshold value.

After processing,we get max = 7695, min = 2562,thus we can combine the grayscale which contains less pixels at both ends together and map the concentrated region which contains great majority of pixels.

Linear compose the detail image and the base image after processing.

Compose the enhanced detail image and the compressed base image to obtain the composite image, which is our desired 8-bit enhanced output image.

To adjust the proportion of the two parts[2] in the result, multiply a factor of k to the base image, which called linear weighted composition method in the composite image:

$$f^{out}(i,j) = P\left\{f^{detail}(i,j)\right\} + kQ\left\{f^{base}(i,j)\right\} \quad (4)$$

Where the final 8-bit output composite image is $f^{out}(i,j)$, k is the weighting factor of base image in the output image,which can be adjusted according to actual situation. For example,a typical value of k is 0.8.

The result of experiment and analysis.

In the end，program the algorithm above-mentioned by using C++, and verify the processed image processing in Matlab simulation. As is shown in figure 1, the 14-bit original infrared image is captured by the infrared thermal imaging system which is independently researched by our laboratory. The infrared image after noise reduction, base image, detail image and enhanced detail image, which are processed from figure 1, are shown in figure 2. As is shown in Figure 3 (d), the detail information of the image has been preserved and enhanced obviously. In order to test the adaptability of the method further, we capture another group of infrared images with high dynamic range in different scenes by the infrared thermal imaging system which is independently researched by our laboratory. The group of infrared images shown in figure 3 contains abundant detail information, which has better enhancement effect after processed by the algorithm mentioned in this paper.

Summary

The new enhancement algorithm of infrared images based on dual threshold of the exponential transform mentioned in this paper, compresses scene information of the global large dynamic range reasonably ,on the basis of effective noise suppression;which not only compress the infrared image with large dynamic range,but also enhance the detail information of infrared image.Thereby the algorithm focus more on the extraction and enhancement of detail information, while improving the contrast of image,leading to the exaltation of the visual sense obviously.

Keywords: dehazing; dark channel prior; LP filter; guided image filter

Abstract. In order to improve the quality of haze degraded image, a novel method is proposed combining dark channel prior and the atmospheric degradation model. Firstly, adaptive block is performed to acquire the dark channel image; then, in HSV space, laplacian pyramid filter is required to obtain the low pass portion of V, further compensated by the single scale Retinex to achieve the final atmospheric light; moreover, for the smoothness trait of guided filter and its fast operation rate, it is suggested to gain the optimal transmission map. Experimental results show that this algorithm can effectively improve the visibility of the optical imaging system.

Introduction

Images of outdoor scenes are usually degraded by the turbid medium which greatly affects the normal operation of most automatic systems. Therefore, the technique Dehazing of Atmospheric Degradation Image (DADI) improves the visibility of degraded images by weakening the effect of haze, having vitally important research meanings [1].

The dehazing methods can be divided into two categories: image enhancement and image restoration. The former enhances the color and contrast of the degraded images based on the human visual system [2], but may lose some information. While the latter establishes the atmospheric scattering model to obtain sharp image [3]. He [4] proposes a simple but effective DCP to remove haze from a single input image, while the method of fixed threshold to estimate atmospheric light is not accurate enough, and the soft-matting has high complexity in time and space .

In this paper, based on DCP, LP-filter[5] and SSR (Single Scale Retinex) compensation algorithm[6] is introduced to estimate the atmospheric light instead of fixed threshold in He's algorithm, and the guided filter is utilized to refine the atmospheric transmission map.

Monochrome atmospheric scattering model

McCartney put forward the widely used monochrome atmospheric scattering model

$$I(x,y)=t(x,y)J(x,y)+(1-t(x,y))A \tag{1}$$

Where the first term is the direct attenuation, and the second term is airlight. And $I(x,y)$ is the observed intensity, $t(x,y)$ is the atmospheric transmission, A is the atmospheric light, and $J(x,y)$ is the scene radiance. The goal of haze removal is to recover $J(x,y)$.

Our algorithm

2.1 Getting dark channel image based on adaptive partition

The dark channel image $J_{dark}(x,y)$ can be expressed as following:

$$J_{dark}(x,y)=\min_{c\in\{r,g,b\}}(\min_{\Omega}(J_c(x,y))) \tag{2}$$

Where $J_c(x,y)$ is a color channel of $J(x,y)$ and Ω is a local patch centered at (x,y), whose size is extremely important for the estimation of transmission. To seek the balance between abundance and distortion, we regard the maximum of row and column of 3% as the size of Ω.

$$block = round(\max(M, N) \times 3\%) \tag{3}$$

The transmission map from our adaptive blocking is more natural and real.

2.2 Estimating atmospheric light

The algorithm is as follows：

(1)Transform the hazy image from RGB space to HSV space to get V component,

$$V = \max(\boldsymbol{I}_R, \boldsymbol{I}_G, \boldsymbol{I}_B) \tag{4}$$

(2)Decompose V component to get VL using LP filter[4],

$$c[n] = \sum_{k \in Z^d} V[k] h[Mn - k] = \langle V, \tilde{h}[-Mn] \rangle \quad VL[n] = \sum_{k \in Z^d} c[k] g[n - Mk] = \sum_{k \in Z^d} \langle V, \tilde{h}[-Mk] \rangle g[n - Mk] \tag{5}$$

Where $h[-n] = \tilde{h}[n]$ is the impulse response of LPF, M is a $d \times d$ scale integral sample matrix；

(3)Employ SSR algorithm to compensate the luminance of VL to get VLC as the estimation of atmospheric light A.

$$F(x,y) = \frac{1 - \varepsilon((x - x_0)^2 + (y - y_0)^2 - 2)}{8} \tag{6}$$

Where (x_0, y_o) is the center point of the function， $\varepsilon(\cdot)$ is a step function.

2.3 Atmospheric transmission refinement

The initial atmospheric transmission is acquired as following:

$$t_1(x,y) = 1 - \omega \min_c (\min_{\Omega} \frac{I_c(x,y)}{A}) \tag{7}$$

Where ω is introduced to acquire more real dehazed image, which is set to be 0.95.

Now we define the following functions: the initial atmospheric transmission map t_1, guided image I, refining transmission map $\hat{t}$, where t_1 acts as the input image while I represents the original hazy image. When guided image I is a color image of multichannel, the local linear model can show as follows:

$$\hat{t}_i = \mathbf{a}_k^T \mathbf{I}_i + b_k, \forall i \in \omega_k \tag{8}$$

Where $\mathbf{I_i}$ and $\mathbf{a_k}$ are 3-by-1 vectors denoting color and linear coefficient, respectively, while $\hat{t}_i$ and b_k are all scalar quantities, which all can be obtained using the algorithm in [7].

(a1)He's refined map (a2)our refined map (b1)He's refined map (b2)our refined map

Fig.1 Comparison of refined map

When a refined transmission map is gained through guided filter, we can further achieve the final dehazed image $J(x,y)$:

$$J(x,y) = \frac{I(x,y) - A(x,y)}{\max(t(x,y), t_0)} + A(x,y) \tag{9}$$

A typical value of t_0 is 0.1, avoiding too small transmission value.

3 Experimental results and analysis

All the experimental data is based on Matlab R2010a.By comparison experiment of two haze degraded images, we can further confirm the performance of our algorithm. Results are shown in Figure 2:

(c1)Original image (c2)He's result (c3)Our result (d1)Original image (d2)He's result (d3)Our result

Fig.2 Comparison with He's result

After the subjective assessment, we quote [8] to make objective evaluation. We observed that the S component information entropy of original non-degraded images is much larger than that of haze degraded ones. Based on our observation, the overall color quality index Q can be expressed as its S component information entropy.

$$Q = \frac{-\sum_{i=0}^{255} p(x_i)\lg(p(x_i))}{m} \tag{10}$$

Where $p(x_i)$ defines the proportion of i-gray-level pixels in a whole image; m is a normalization factor with a value of 10. The result is demonstrated in Table 2. For the fastness of the proposed method, we make a comparison in calculation time. As shown in Table 3, our algorithm is far more efficient than He's.

Table 2 Image color quality index Q

Q	Degraded image	He	Our method
c	5.2849	6.5508	7.8809
d	4.1147	6.7613	7.2492

Table 3 Comparison in calculation time

Image number	He's method	Our method
c	48.075672	2.07955
d	44.585169	1.889495

4 Conclusions

In this paper, we propose a novel DADI algorithm based on DCP and with the combination of atmospheric scattering model. Firstly, we get the dark channel by adaptively blocking, and then obtain atmospheric light through LP filter and SSR compensation algorithm, and use guided filer to refine the transmission to achieve the vivid image. Whatever in subjective and objective evaluation, our results perform better than He's both in operation speed and image quality.

Keywords: OFDM, Space-time Coding, channel estimation

Abstract. This research is conducted with the objective of improving the OFDM system in coal mines with regard to its defects and puts forward a structure diagram of STBC-OFDM transceiver for systems which require low complexity with a simulation of the system performance. Through the simulation, in which the STBC-OFDM communication system in coal mines is employed, the BER performance of the OFDM system is improved and the complexity and cost of the receiver is lowered with a significant reduction in daily maintenance.

1. Introduction

With added guard intervals in the OFDM system, the intersymbol interference in multipath transmission is eliminated with the spectrum efficiency enhanced, and the use of IFFT/FFT baseband reduces the complexity of the equipment. The OFDM system, however, is easily affected by frequency deviation and time-varying channels[1], yielding a high PAR and increased cost for equipments. Therefore, the combination of space-time coding[2] [3] [4] and OFDM technology[8] can promote the anti-fading ability of the system and lower the BER in transmission[5] [6].

2. Space-time Coding OFDM System

A space-time coding OFDM system with 4 emitting antennas and $p(p \geqslant 4)$ receiving antennas as is shown in Diagram 1.

In the moment n, either of the two data blocks $\{b_i[n,k]: k=0,1,\cdots\}$, $i=1,2$, when passing space-time coding, are converted into two different data sequences $\{t_{2(i-1)+j}[n,k]: k=0,1,\cdots, j=1,2\}, i=1,2$. After being space-time coded, the k[th] voice OFDM signal in the n[th] data block of the i[th] emitting antennas becomes $t_i[n,k]$.

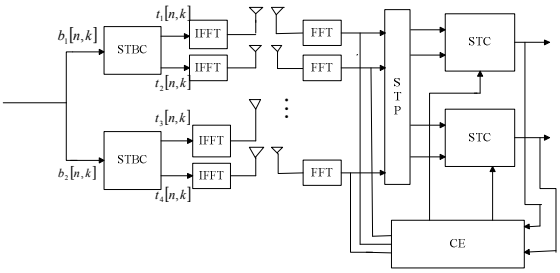

Diagram 1. Model of STBC-OFDM System

It can be seen from the diagram that the signal received by the receiving antenna is the superposition of 4 distorted signals from the transmitter, which can be expressed as

$$r_j[n,k] = \sum_{i=1}^{4} \mathbf{H}_{ij}[n,k] t_i[n,k] + w_j[n,k] \quad (j=1,\cdots,p) \qquad (1)$$

$w_j[n,k]$ represents that the mean of the is 0 with a variance of σ_n^2 and it also means the complex gauss noise which is additive and unrelated of different moments. $\mathbf{H}_{ij}[n,k]$ represents the frequency response of the k^{th} voice signal between the i^{th} emitting antenna and the j^{th} receiving antenna at the moment of n.

3. Statistical Features of MIMO Channel

The baseband signal in the impulse response of mobile wireless channels can be expressed as

$$h(t,\tau)=\sum_{k}\gamma_k(t)c(\tau-\tau_k) \quad (2)$$

τ_k is the delay of the k^{th} path, $\gamma_k(t)$ is the amplitude, and $c(t)$ is the shape of the impulse. With regard to the movement of the mine car in the tunnel, it can be assumed that $\gamma_k(t)'s$ is the complex gaussian process of the narrow band in Wide-sense stationary (WSS) and each path is independent. The average power of $\gamma_k(t)'s$ is determined by the distribution of channel delays, which is affected by the environment. For the convenience of research, it is assumed that the corresponding emitting and receiving antennas in the MIMO system have the same distribution of delays.

4. Enhanced Channel Estimation

$h_{ij}[n,l]$ is estimated in terms of time and frequency with the relevance of channel parameters. The channel frequency response of $\hat{h}_{ij}[n,l]$, the estimated $h_{ij}[n,l]$, is reconstructed as

$$\widehat{H}_{ij}[n,k]=\sum_{l=0}^{K_Q-1}\hat{h}_{ij}[n,l]W_K^{kl} \quad (3)$$

$\hat{h}_{ij}[n,l]$ contains the actual channel parameter $h_{ij}[n,l]$ and the estimated error $e_{ij}[n,l]$. That is

$$\hat{h}_{ij}[n,l]=h_{ij}[n,l]+e_{ij}[n,l] \quad (4)$$

The mean of $e_{ij}[n,l]$ is 0 and its variance is σ^2. $i's$, $j's, n's$, or $l's$ are independent gauss signals at different moments.

If the distribution of channel delays is given and when $l=0,\cdots,K_o-1\ \sigma_l^2$ are given and they are used to reconstruct the channel frequency response from $\hat{h}_{ij}[n,l]$, the Mean Square Error (MSE) of $\widehat{H}_{ij}[n,k]$ decreases rapidly. When α_l of the minimum NSME is selected at the moment

$$\widehat{H}_{ij}[n,k]\triangleq\sum_{l=0}^{K_Q-1}\alpha_l\hat{h}_{ij}[n,l]W_K^{kl} \quad (5)$$

Therefore, the optimal α_l after calculation is

$$\alpha_l=\frac{\frac{\sigma_l^2}{\sigma_l^2+\sigma^2}}{\sum_{m=0}^{K_o-1}\frac{\sigma_m^4}{\sigma_m^4+\sigma^2}} \quad (6)$$

And NMSE is

$$NMSE_O=\frac{\sigma^2\sum_{m=0}^{K_o-1}\frac{\sigma_m^2}{\sigma_m^2+\sigma^2}}{\sum_{m=0}^{K_o-1}\frac{\sigma_m^4}{\sigma_m^4+\sigma^2}} \quad (7)$$

The distribution of channel delays is partly dependent on the environment, so it is usually unknowable for users. For MIMO-OFDM system, however, different emitting and receiving antennas are considered to have the same delay distribution. Thus, $\sigma_l^2\triangleq E\left\|h_{ij}[n,l]\right\|^2$ can be estimated as

$$\hat{\sigma}_l^2=\frac{1}{4p}\sum_{i=1}^{4}\sum_{j=1}^{p}\left|\hat{h}_{ij}[n,l]\right|^2 \quad (8)$$

and σ_l^2 is further calculated.

Suppose the frequency of communicaton in the coal mine is 2GHz, it is considered that the noise in the system is additive white noise with a given variance so that the mechanical and electrical noises can be avoided. Enhanced channels are estimated to be not sensitive to noise variance, so this figure is considered to be σ^2 when the SNR (Signal to Noise Ration) is 10 dB.

5. Simulation Analysis

A simulation is conducted on the space-time coding of different numbers of antennas based on the simulated parameters in Diagram 1. It can be seen from Diagram 2 that the use of STBC-OFDM communication system in coal mines improves the BER performance of the OFDM system, and reduces the complexity and cost of the receiver with a significant reduction in the need for daily maintenance. See Table 1.

Table 1. Physical layer parameter of ofdm

Parameter	**Value**
Working frequency	2000MHz
System bandwidth	20MHz
Sub-carrier number	64
Sub-carrier interval	0.3215MHz(20MHz/64)
Valid symbol period	3.2us(1/0.3125)
Guard interval	8.0us
Symbol period	4us
Modulation mode	Qpsk
Maximum transmit speed	26Mbits/s □

Keywords: Gabor wavelet, GLCM, SVM classifiers.

Abstract. This paper presents a texture classification algorithm using Gabor wavelet and Gray Level Co-occurrence Matrix as feature extraction method and Support Vector Machine as classifier. Gabor transform and Gray Level Co-occurrence Matrix are used to get the features of the digital images, SVM classifiers are followed to build image and realize classification. The results of the experiments have shown that the methods described in this paper can improve the rate of correct classification effectively than traditional method of classification.

1. Introduction

Image feature is the foundation of image understanding, the main features of image include color, texture and shape. Texture is an important feature of the image, which is the nature of spatial distribution characterization of pixel neighborhood gray level. Texture is texture primitive regular permutation and combination, texture element is a repetitive, consistent intensity of simple shape regional and image pixel is the smallest texture primitive. Domestic and foreign experts have conducted a lot of research on the image texture such as wavelet transform, texture, co-occurrence matrix and Markov random field. These methods can be roughly divided into statistical analysis method, model method, frequency domain analysis method, and structure analysis method. The statistical analysis method is most widely used, and fruitful research achievements have been made in the field of computer vision and pattern recognition. Mineral picture itself also has these characteristics. However, mineral structure differs in thousands of ways and the difference in impurity content of the ore lead the mineral difficult to recognize. A simple combination of simple texture, color, hardness and the color of texture is not enough to identify the complex image effectively, so, new image feature extraction method is needed.

2. Texture features extraction based on Wavelet Transform

Gabor wavelet is an important method of image texture feature extraction, with the good robustness of illumination and pose, Gabor wavelet is widely applied to the field of image recognition.

Definition of two-dimensional Gabor wavelet :

$$\psi(\kappa, z)=\frac{\|k\|^2}{\sigma^2}\exp\left[-\frac{\|k\|^2\|z\|^2}{2\sigma^2}\right]\cdot\left[\exp(ikz)-\exp\left[-\frac{\sigma^2}{2}\right]\right]$$

σ is a constant associated with the wavelet frequency bandwidth. $z=(x,y)$ is position coordinate space. k determines the direction and scale of the Gabor kernel. In the sample with 8 directions and 5 scales, scale and direction of the k can be written as $k_{\mu,\nu}=k_\nu e^{i\phi_\mu}$. $k_\nu=k_{\max}/f^\nu$ is sampling scale, $\nu\in\{0,1,\cdots,4\}$ is scale label. $\Phi_\mu=\pi\mu/8$ is sampling direction, $\mu\in\{0,1,\cdots,7\}$ is direction label. $k_{\max}$ is the maximum frequency, f is kernel interval factor in the frequency domain. Assume that $k_{\max}=\pi/2$, $f=\sqrt{2}$, $\sigma=2\pi$, the wavelet representation and identify will be better.

Gabor transform and convolution kernel is : $J_k(z) = \mathrm{I}(z) * \Psi(k, z)$

Assume that the amplitude of $J_k(z)$ is A_k and the phase of $J_k(z)$ is ϕ_k , $J_k(z) = \mathrm{A}_k e^{i\phi_k}$, so Gabor feature vector images in z position can be get by grouping different scales and directions of $J_k(z)$ together.

3. Texture feature extraction based on the gray level co-occurrence matrix

As the computation loads of the gray level co-occurrence matrix are still very high, for simplicity, five most commonly used features are used to extract image texture feature:

(1) Angle of second moment (energy)

$$ASM = \sum_i \sum_j p(i, j)^2$$

Angle of second moment is square of all gray level co-occurrence matrix elements, it is also known as energy. It is a measurement of image texture gray change uniform, reflecting the image gray distribution uniformity and texture coarseness. If all the values are equal in co-occurrence matrix, the value of ASM is low; on the contrary, if some values are large and others are small, ASM is high. A image with same gray level has only one value in its image gray level co-occurrence matrix, which is equal to the total number of pixels, it is also the largest ASM value. Therefore, the ASM value indicates that the change is uniform and in regular texture pattern.

(2) Contrast (moment of inertia)

$$CON = \sum_i \sum_j (i - j)^2 p(i, j)$$

The contrast is the gray level co-occurrence matrix main diagonal of the moment of inertia of nearby, it is a measurement of values distribution in matrix and local change in the image, reflecting the image clarity and the groove depth of texture. The groove depth of texture is large, contrast is also large, the image is clear; on the contrary, contrast is low, groove depth becomes shallow, the image is fuzzy.

(3) Entropy

$$ENT = -\sum_i \sum_j p(i, j) \log(i, j)$$

Entropy is a measurement of image texture stochastic. When all values in the spatial co-occurrence matrix are equal, it gets the maximum value; on the contrary, if the co-occurrence matrix values are not uniform, the value becomes smaller. Therefore, the maximum entropy implies that the image gray level distribution is completely random.

(4) Inverse Difference Moment (local stationarity)

$$IDM = \sum_i \sum_j \frac{1}{1 + (i - j)^2} p(i, j)$$

It is used to measure how much the texture local changes. The value is large indicates image texture between different region is lack of change, local region is very uniform.

(5) Variance of sum $f_{10} = p_{x-y}$

Figure.1 is the extraction algorithm based on features of gray level co-occurrence matrix. In the feature extraction of the texture, the brightness of the image is divided into 256 gray level and form a gray co-occurrence matrix in 4 directions, $p_{(1,0)}, p_{(0,1)}, p_{(1,1)}, p_{(1,-1)}$, computation loads of the co-occurrence matrix is determined by the gray level and size of the image. Assume that the image G has L gray level, and its size is R row and C column, the computation loads approximate to $L^2 * R * C$. Then calculating five texture features vectors of the co-occurrence matrix in 4 directions, second moment, entropy, contrast, inverse difference moment and the variance of sum. Finally, texture characteristic vectors are constituted by the five features.

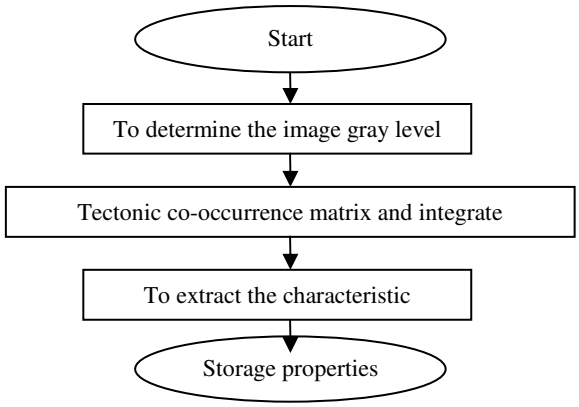

Fig. 1 Algorithm

4. Support vector machine (SVM)

Generally speaking, the support vector machine firstly transforms the input space into a high dimension space by a nonlinear transformation defined by the inner product function, then for (generalized) optimal classification level. SVM classification function is similar to a neural network, the output is a linear combination of several intermediate nodes, and each node in the middle layer of the input sample and a support vector inner product. Support vector machine is a process in which the image is divided into different classes, and makes the data objects in the same class with the higher similarity. Similar or dissimilar description is to determined by image description value. The classification of level is a nonlinear function, and in theory the input space should be mapped to a high dimensional feature space by a nonlinear mapping. There are linear categorization rules in this space, and you can construct a linear optimal classification hyperplane.

Firstly, the input vector x is mapped to a high-dimensional Hilbert space H by the mapping $\Psi : R^{\mathrm{n}} \to H$. A kernel function K satisfies: $K(x_i, x_j) = \Psi(x_i) \cdot \Psi(x_j)$.

The objective function of a quadratic programming problem into two: Maximize

$$W(\alpha) = \sum_{i=1}^{l} \alpha_i - \frac{1}{2} \sum_{i=1}^{l} \alpha_i \alpha_j \mathrm{y}_i \mathrm{y}_j \{\Psi(x_i) \cdot \Psi(x_j)\} = \sum_{i=1}^{l} \alpha_i - \frac{1}{2} \sum_{i=1}^{l} \alpha_i \alpha_j \mathrm{y}_i \mathrm{y}_j K(x_i, x_j)$$

$$s.t. \qquad \sum_{i=1}^{l} \alpha_i \mathrm{y}_i = 0 \quad C \geq \alpha_i \geq 0 \quad i = 1,2,\cdots,l$$

When the training is completed, the following function symbols are only needed to compute.

$$f(x) = \mathrm{sgn}\left[\sum_{\text{support vector}} \alpha_i \mathrm{y}_i K(x_i, x) - b \right]$$

In the formula, b is the offset value:

$$b = \frac{1}{2}\left[\sum_{i=1}^{l} \alpha_i \mathrm{y}_i \Psi(x_i) x^*(1) + \sum_{i=1}^{l} \alpha_i \mathrm{y}_i \Psi(x_i) x^*(-1) \right]$$

In the formula, $x^*(1)$ represents a support vector(everyone) belongs to the first class. $x^*(-1)$ represents a support vector belongs to the second class. Usually, it is no use to know Ψ and H directly. The support vector machine can be determined by selecting a appropriate kernel function K. The Mercer theorem points out the necessary and sufficient conditions that kernel function K must satisfy: for any function g (x) meets the condition: $\int g(x)^2 dx < \infty$, $\iint K(x, y) g(x) g(y) dx dy \geq 0$ is permanent establishment.

Different support vector machines can be made by selecting the kernel function K of different forms, common use are as follows:

(1) Polynomial SVM (when d=1, it is linear kernel): $K(x,y)=[(x\cdot y)+1]^d$.

(2) Radial basis function SVM: $K(x,y)=e^{-\|x-y\|^2/2\sigma^2}$.

(3) Sigmoid function SVM: $K(x,y)=\tanh(k(x\cdot y)+\delta)$.

As the RBF kernel has only two parameters, just C and G, which are needed to be defined with less computation loads. So this article uses the radial basis function.

4. Analysis of the experimental results

Selecting iron ore, copper ore and garnet images to test the image texture characteristics. Images of 10,5,3,1 were selected as the training samples, and according to the five characteristics of the calculated value, training in SVM classification machine based on kernel RBF. Then a test was applied according to other 30 obtained classification models. Test results are showed in Fig.2. This paper provides the method that based on Gabor wavelet and gray image co-occurrence matrix by training and classifying a support vector machine to realize the judging of image authenticity. The experimental results show that the classification effect of the five typical characteristics of the RBF kernel based on SVM is good. More samples will make the test accuracy be better. But the classified results also have some effects on the difference between typical and heterogeneous images samples. In this paper, the feature extraction is good. While processing different kinds of mineral image, it is clear to see that the extraction algorithm is general for ore image, the extraction algorithm has played a good role in understanding and classifying ore.

Samples	C	G	Accuracy
10	1.9	0.5	Three species are all 100%
5	7.8	0.5	Three species are all 100%
3	0.031	0.5	Iron ore：75%，Copper ore：80%，Garnet：87%
1	0.031	0.0077	Iron ore：70%，Copper ore：76%，Garnet：79%

Keywords: Lifting wavelet transform, image compression, wavelet transform.

Abstract. Because the operational speed of the traditional image compression based on Mallat algorithm is slow, and auxiliary Storage space is occupied, image compressed method based on lifting wavelet transform is proposed, in order to realize its versatility, flexibility and high efficient. Experiments show that the lifting wavelet transform, is easy to realize integer wavelet transform can be used for lossless compression, and has higher compression ratio.

Introduction

The theory's basis of image compression is that there exists many redundant data[1] in the image. First, we need to know taht data and information are two different concepts. Data is the carrier of information and expression. Content as existing in the data which has nothing to do with the information is redundancy. Image compression is to reduce the redundant data to reduce the amount of data transmission and storage. Generally considered static image data redundancy mainly concludes the followings: (1) spatial redundancy; (2) visual redundancy; (3) coding redundancy[2-3].

Image coding mainly includes entropy coding, predictive coding, transform coding[4] and vector four basic coding methods. For all kinds of coding method to formulate unified specification, international telecommunication union and the international organization for standardization on the basis of the original static image compression standard JPEG, in 2000 a new generation of still image compression standard JPEG2000[5]. The standard use wavelet transform to replace discrete cosine transform (DCT), and makes the JPEG2000 standard can be applied to upon, including medical, remote sensing and mobile communications and other fields, all kinds of image compression, have become the 21st century the main static image compression standard.

Wavelet transform theory

In the field of image compression and coding, wavelet transform's basis idea is to decompose the image into different space and frequency of sub images, we called it a multiresolution decomposition[6-8]. After transformation the energy mainly concentrated in low-frequency subband image parts, high frequency subband energy is less. After wavelet transform of the image, all the sum total of the amount of image data in the subspace and the original image is equal to the amount of data, transform itself has no compression.Compression function is mainly in the subsequent quantization and coding and other steps.

Set function $\psi(t) \in L^2(R)$, if meet the permitting conditions $C_\psi \int_{-\infty}^{+\infty} \frac{|\phi(\omega)|}{|\phi|} d\omega < \infty$ $\psi(t)$ as a basic wavelet, the $\varphi(t)$ as the bits of Fourier transform $\psi(t)$.

Continuous wavelet transform is defined as:

$$W_f(a,b) = \frac{1}{\sqrt{|a|}} \int_{-\infty}^{+\infty} f(t) \psi^*(\frac{t-b}{a}) dt \tag{1}$$

For the scale factor of a, b for translation factor, a≠0,b, t are continuous variables, $\psi_{(a,b)}(t)=\frac{1}{\sqrt{|a|}}\psi(\frac{t-b}{a})$ is the mother wavelet $\psi(t)$ generated the wavelet, said $\psi^*(t)$ is the conjugate complex of $\psi(t)$.

The energy formula shows after wavelet transform the integration of signal amplitude square is proportional to the signal energy before ransform. Wavelet transform redistributes the energy of original signal, while the coefficient after wavelet transform completely retains the original signal information.

Discrete Wavelet Transform. In order to be able to apply wavelet transform on the computer, you need to discrete continuous wavelet operations and convert it into a binary wavelet. Make $a=2^{-m}, b=n2^{-m}\ \ n,m\in Z$ (Z is the set of integers), then the discrete binary wavelet is

$$\psi_{m,n}(k)=2^{m/2}\psi(2^m k-n), k\in Z \tag{2}$$

The signal $f(t)$ take discrete value $f(k)$, $k\in Z$,and $f(t)\in L^2(Z)$, that is $\sum_{k\in Z}|f(k)|^2<+\infty$, then wavelet transform of the discrete binary of $f(k)$ is:

$$A^0 f(x,y)=D^1 f(x,y)+D^2 f(x,y)+...+D^n f(x,y)+A^n f(x,y) \tag{3}$$

Accordingly, the inverse transform is:

$$f(k)=\sum_{m\in Z}\sum_{m\in Z}W_f(m,n)\psi_{m,n}(k)\ \ m,n,k\in Z \tag{4}$$

When a=2 and b=1, the Discrete Wavelet form is described as below.

$$\psi_{j,k}(t)=2^{-j/2}\psi(2^{-j}t-k)\quad j,k\in Z \tag{5}$$

And it is called Dyadic wavelet.

The Mallat algorithm of One-dimensional discrete wavelet transform. In the year of 1987, Mallat put forward the concept of multi-resolution analysis, and gave the method of orthogonal wavelet and its fast algorithm, that is the Mallat algorithm.

According to the theory of multiresolution analysis, we can conclude the fast decomposition algorithm expression of one dimensional discrete wavelet transform:

$$c_{j,k}=\sum_m h(m-2k)c_{j-1,m} \tag{6}$$

$$d_{l,k}=\sum_m h(m-2k)g_{j-1,m} \tag{7}$$

Where h and g are the decompositions of low-end, high-pass filter respectively. Its fast reconstruction algorithm can be expressed as

$$c_{j-1,m}=\sum_k c_{j,k}h(m-2k)+\sum_k d_{j,k}g(m-2k) \tag{8}$$

The $\overline{h}$ and $\overline{g}$ are the low, high-pass filter of reconstruction respectively. Where $c_{j,k}$, $d_{j,k}$ are respectively scale coefficients and wavelet coefficient of the scale j, and $c_{j-1,m}$ is the scale coefficient of the scale $j-1$.

The decomposition and reconstruction of two-dimensional discrete wavelet transform. Images of two-dimensional discrete wavelet transform are based on the one-dimensional discrete wavelet transform of signal. And it is the 2d extension of one-dimensional discrete wavelet transform. Each level of the image wavelet transformation can be divided into two steps. To begin with, we should make one-dimensional wavelet transform for the rows or columns of the image and then transform data in columns or rows in a one-dimensional wavelet transform. In the field of engineering application, we use digital filter and the sampling to realize two-dimensional discrete wavelet transform of the image.After wavelet transform, the original image is decomposed into four sub images, which are corresponding to the four zones respectively:

a) LL sub-band: low-frequency sub-graph, which is the overview of the corresponding image in the next dimension.b) LH sub-band: vertical high-frequency sub-graph, which is detail information of images in the horizontal direction of the scales.c) HL sub-band: level high frequency sub-graph, which is detail information of images in the vertical direction of the scales.d) HH sub-band: diagonal high-frequency sub-graph, which is detail information of images in the diagonal direction of the scales. As is shown in figure 1:

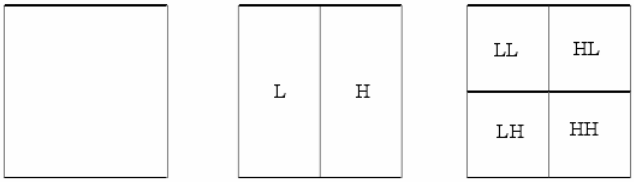

Fig.1, Schematic diagram of two-dimensional Wavelet transform

Fig.2, Decomposition example of two-dimensional Wavelet transform

Lifting wavelet algorithm

The basic idea of improving the algorithm is to break down finite lifting wavelet filters into some basic building blocks, and complete the wavelet transform step by step. Lifting algorithm is divided into three steps: division, forecast and update. Specific methods are as follows:

Division:

Set $x(n)\ (n=0,1,2\cdots,N)$ is the original sequence of discrete signals, which is divided into an odd sequence $x(2n+1)$ and an even-numbered sequence $x(2n)$ and they are two disjoint subsets mutually. As shown in this formula:

$$\{x(2n),x(2n+1)\}=Split(x(n)) \tag{9}$$

Forecast:

Because of the original data's dependencies, so you can take advantage of even-number $x(2n)$ to predict odd sequence $x(2n+1)$ .Set $p(\cdot)$ is predict operator, $p(x(2n))$ is the forecast value of even sequence, using the error between the value of $x(2n+1)$ and forecast value to represent detail information $d(n)$ .As shown in the formula (12):

$$d(n)=x(2n+1)-p(x(2n)) \tag{10}$$

In the lifting wavelet transformation, the prediction has the following two functions:It can represent the data in the form of a compact.Utilizing the local correlation of original signal sequence $x(n)$ during various elements, which can be used to predictive error $d(n)$ and predictive value of $p(x(2n))$ of even number sequence $x(2n)$ to predict the odd number sequence $x(2n+1)$.

It can isolate the high frequency component of signal $x(n)$ in the spatial domain:

We can predict that point by a smooth curve which goes through the near point of $x(2n+1)$ in the prediction, The smooth can be looked as the low frequency component of $x(n)$. The error of prediction $d(n)$ is the error after comparing a sequence $x(n)$ with their low frequency component in local area, so it can be viewed as the signal high frequency component of $x(n)$.

Update

For to maintain the overall of characteristics of the original sequence $x(n)$, $x(2n)$ must be updated. The purpose is to find out a subset of the data $c(n)$ which is able to maintain certain scale features of the original sequence $x(n)$ better. We can use the prediction error of d(n) to update even number

sequence $x(2n)$ to get data subset of $c(n)$. As shown in type (12), of which $U(\cdot)$ represents update operator.

$$c(n) = x(2n) + U(d(n)) \tag{11}$$

The reconstruction process of signal sequence $x(n)$ is the reversing process of above three steps, which are divided into three steps including anti update, anti prediction and merging.

1. Anti update

We can recover even number sequence by undo update formula (13) and sequence of $c(n)/d(n)$.

$$x(2n) = c(n) - U(d(n)) \tag{12}$$

2. Anti prediction

By the anti-prediction formula (14), sequence $x(2n)$ and $d(n)$ can restore the odd sequence.

$$x(2n+1) = d(n) - p(x(2n)) \tag{13}$$

3. Merger

We can restore the original signal sequence x(n) by the merger formula (14) and even.

$$x(n) = Merge\{x(2n), x(2n+1)\} \tag{14}$$

Lifting wavelet transform decomposition and reconstruction of the principle shown in Figure 3.

Fig.4, The image of using wavelet transform image compression

A. The original image B. The final image

Figure 5. The image of using traditional wavelet transform image compression

A is the original image, B is three layers of decomposition by the lifting wavelet transform, C is the image using the wavelet transform image compression in Figure 4.

In Figure 5, A is the original image and B is the final image by the traditional wavelet algorithm. The data are shown in Table I.

Compared with the wavelet transform, the lifting wavelet transform has the following main advantages:

A: The whole calculation process does not require auxiliary storage space, for this the lifting wavelet transform can operation in the situ. So compared with the additional Mallat algorithm, speed of wavelet transformation is significantly enhanced. And the lifting wavelet transform significantly enhance the computing speed is a repid and practical method of the wavelet transform.

B: Compared wavelet transform, the image reconstruction error by the lifting wavelet transformation is smaller, and the PSNR is larger than the traditional wavelet transformation to ensure integrity of image information.

Table 1 Arithmetic comparison of the image in to algorithms

Algorithm	The original size	Picture size after compression	Compression ratio	PSNR(db)	Time(s)
The traditional wavelet transformation	262144	154568	1.6959:1	25.78665	0.560248
This algorithm	262144	26208	10:1	33.168459	0.734843

Conclusion

As a key link in the process of information transmission, image compression and coding is a greatly key area of research in the field of communication. As one standard of image compression, The lifting wavelet transformation of JPEG2000 has more advantages than the traditional wavelet transformation in some aspects. Experiments show that, image compression of lifting wavelet transformation in this article is relatively improved than the traditional wavelet transform in both PSNR and the operation time.

Keywords: Signal optimization; Surrogate measures; objective optimizationl evolutionary algorithms

Abstract. One alternative mathod to improve safety of signalized arterials is to optimize signal timings. Historically, signal retiming tools were used to reduce traffic delay and stops and other measures of traffic efficiency such as closed-loop systems in California and United States. The concept of optimizing signal timings specifically to improve safety metrics, or their surrogate measures, is not common in current signal timing optimization practice. This study advocates a fresh approach to integrating VISSIM microsimulation software, Surrogate Safety Assessment Model, and VISSIM-based Genetic Algorithm for Optimization of Signal Timings to reduce surrogate measures of safety and thereby reduce risks of potential real-world crashes. In addition, a multiple-objective genetic algorithm is implemented to identify the optimal compromise between two competing objectives: surrogate safety and traffic efficiency.

1 Introduction

One way to improve safety of signalized arterials is to retime traffic signals. Well-coordinated traffic signals provide good progression for major vehicular streams previous to reducing the number of necessary stops and the potential for rear-end collisions. In addition, balanced splits provide more equitable green times for all traffic movements thus reducing potential for unsafe operations of 'unfairly treated' traffic movements. However, in spite of the common belief that proper signal timings promote safe traffic operations, evidence from the field to support this perception is lacking. The Highway Safety Manual states that several signal timing-related crash-reduction treatments (e.g. modifying cycle length and phase durations, and improving signal coordination) have unknown effects on crashes.

There are two major reasons for an inability to investigate impacts of signal timings on traffic safety at intersections on arterial streets. First, field evaluations of safety improvements obtained by tweaking signal timings are impractical and often inconclusive. Relationships between crash rates and potential causes are relatively low even when those causes (e.g. weather, geometrical design of the roads, and presence of work zones) have a much higher impact on traffic safety than signal controllers' timings. Second, unlike other traffic metrics which reflect efficiency of traffic operations, safety impacts have not been traditionally assessed by simulation tools.

An integrated simulation/signal optimization tool can generate, evaluate and fine tune signal timing plans in a cohesive manner. The advancement and deployment of telecommunication and ITS technologies make traffic and signal status data more readily available. These high-resolution data provide opportunities to allow closed-loop control systems to operate more adaptively and robustly to the changes in traffic demands and patterns. Recent research on the use of surrogate measures of safety to assess quality of various operational alternatives through micro-simulation has brought new perspectives to this field [1] . Several microscopic simulators are currently equipped to generate vehicular trajectory data that can be post-processed by the Surrogate Safety Assessment Model

(SSAM) to provide surrogate safety estimates [2]. Although the ability of micro-simulation tools to accuratly model safety aspects of traffic operations is still debated, the approach is gaining momentum and may result in further improvements to the fidelity of micro-simulation tools [3]. Also, estimating surrogate measures of safety is not necessarily equivalent to predicting accidents. Rather, it is a causal relationship similar to other conventional methods that estimate crashes [2].

The concept of optimizing signal timings to directly reduce safety metrics or their surrogate measures is not present in current signal timing optimization practice. Unlike metrics representing efficiency of traffic operations, commonly used signal timing optimization tools (such as Synchro, TRANSYT-7F, and PASSER) are not even equipped to evaluate impacts of signal timings on surrogate measures of safety. Although a recent study addressed impacts of signal timings on surrogate measures of safety, there are many related questions which remain unanswered [4].

This study essentially has two objectives, the first is to propose a novel approach to account for (surrogate) measures of safety when optimizing traffic signal timings on arterial intersections. This addresses a gap in the existing body of knowledge as no similar method has been documented in the literature. The second objective is to investigate the relationship between individual types of signal timings (cycle length, splits and offsets) and the total number of conflicts as estimated by SSAM. HSM (2010) clearly documents that such relationships are lacking.

2 Maximum and minimum green

Traffic demand at the intersection is critical in determining the number of timing plans needed and the actual timings of the phases. If the peak hour flows are significantly greater than off peak and weekend volumes, more than one timing plan should be considered and the maximum green times should be based on the volume splits.

The maximum green interval limits the time a phase can hold the green. When the signal is properly timed with appropriately short vehicle extensions, the maximum green interval will not consistently time out unless the intersection is significantly over capacity. The maximum green interval is typically determined based on a detailed capacity analysis of the intersection. With actuated operation, a maximum green interval of 1.25 to 1.5 times the maximum green time calculated by capacity analysis is generally desirable. This will allow the signal to better react to variations in traffic demand thereby maximizing the efficiency of signal operation. A maximum green interval that is set too low can significantly reduce the benefit of actuated operation. It should be noted that when a signal is running coordinated in a signal system, other considerations (cycle length) may take precedence in determining maximum green times.

The passage time or vehicle extension is the time required for a vehicle to travel from the detector to the stop bar or to the adjacent detector where multiple detection exists. The vehicle extension is also the time required to accommodate the gaps between vehicles. For maximum efficiency the vehicle extension should be set as short as practical to retain the green only as long as a real and consistent demand is present, but should not service vehicles straying behind. However, where detectors are located at some distance from the stop bar, the vehicle extension must be long enough to permit the vehicle to travel from the detector to the intersection without gapping out (See section on Vehicle Detection).

2 Traffic safety and traffic signal timings

When evaluating impacts of signal timings on road safety, the main focus is often on intergreen (yellow + all-red) times, while other signal timing parameters receive little attention.

The impact of intergreen on red-light running and dilemma zones is well documented [5]. However, very few studies have estimated the direct impact due to other signal timing parameters (such as cycle length, offsets, splits and phase sequence). One of the first such studies was conducted by Moore and Lowrie (1976), who investigated the impact of traffic signal coordination on number of traffic accidents in the field [6]. They compared the frequency of accidents from areas with and

without coordinated signals and estimated a 23% reduction in accidents following traffic signal coordination.

In practice, when signals are retimed, consultants usually apply a crash reduction factor to estimate the safety benefits of retiming. However, this approach is not very reliable because crash reduction rates may be based on a limited number of research studies[7]. Another study investigated, among other things, the impact of coordination of signalized intersections on the number of traffic crashes. The study was done for 170 signalized intersections in Florida. The results indicated that coordinated signals experience fewer crashes than isolated signals though the study did not address details of traffic progression between intersections [8]. Finally, the most recent research on safety evaluations of a traffic signal system represents an effort by Midenet et al. (2011) to investigate the exposure to lateral collisions at signalized intersections for two traffic control strategies [9]. The authors compared the timed exposure captured through video recordings from an intersection operating under both an adaptive real-time strategy called CRONOS and a time-plan strategy to vehicle-actuated ranges. The results showed that CRONOS reduced exposure to lateral collisions by roughly 5 min/h.

3 Surrogate measures of safety from microscopic simulations

One of the recent studies using a widely-available simulation model was conducted in 2002 by Drummond et al. when the authors found a high correlation between traffic efficiency performance measures (e.g. delays and stops) from simulation and field crash rates. A major breakthrough in research on surrogate measures of safety based on micro-simulation outputs was achieved when Gettman and Head (2003) developed functional requirements and algorithms for a software tool that analyzed surrogate measures of safety generated by a simulation model. This research led to development of publicly-available SSAM software a few years later [2].

Another recent study has furthermore investigated the impact of signal timings on surrogate safety measures using SSAM to evaluate simulated scenarios [4]. However, that study was performed within a framework limited by Synchro's inability to always find the best signal timings in VISSIM. Earlier studies have shown that when signal timings delivered by deterministic optimization tools are evaluated in stochastic environments their performances may not be optimal nor consistent. In addition, the goal of a Sabra et al. (2010) study was to conduct a sensitivity analysis and evaluate individual impacts of signal timings on surrogate safety measures rather than perform the optimization proposed in this study.

4 VISSIM–SSAM–VISGAOST framework

VISSIM is a microscopic, time step and behavior-based model developed to simulate urban traffic and public transport operations, while SSAM is a software application, sponsored by FHWA, that provides safety analysis for simulation-based comparative studies, and VISGAOST is an optimization program that optimizes signal timings of traffic controllers based on their performance in VISSIM microscopic simulation [2].

The program previously used for similar optimizations was modified to accommodate a new SSAM interface. The optimization process starts with VISGAOST generating an initial population of signal timings, which is seeded by the existing set of signal timings from the field. Each generated signal timing plan is evaluated in VISSIM, which generates both network-wide measures of effectiveness and trajectory data for each vehicle (where outputs are required for subsequent optimization steps).

The trajectory data file is processed by SSAM to identify the frequency, severity and types of conflicts [2]. In the next step the number of conflicts from SSAM is manipulated with some VISSIM performance measures to produce a meaningful objective function for ISGAOST optimization. This objective function is then minimized via the Genetic Algorithm iterative procedure by evaluating various combinations of signal timings from intersection controllers [10] . The whole process is then repeated until the predefined termination criterion is met (using a number of repetitions or convergence of solutions).

Keywords : Laser engraving, Image processing, Process parameters.

Abstract. In 1960 the first ruby laser came out , after 40 years' development, laser engraving technology has been widely used in various areas. This paper describes the characteristics of laser engraving, the advantages and applications in industries and study images of laser engraving key technologies in-depth from image processing, laser engraving process parameters and clean carbide processing , and JK-2030 CO_2 laser engraving machines on paulownia color photos as examples for authentication, making laser engraving images more easily and efficiently .

Preface

Laser engraving is a new engraving technology , following the development of laser technology.Computer-controlled laser is a comprehensive application of computer technology, control technology and laser technology, the laser beam is focused on being irradiated surface sculpture, light energy transfer into heat energy , melting or vaporization instantly processed materials, the formation of holes, with the beam moving along a specific path, the photon interaction with the material, the material surface to form the final desired result kerf.[1-2]

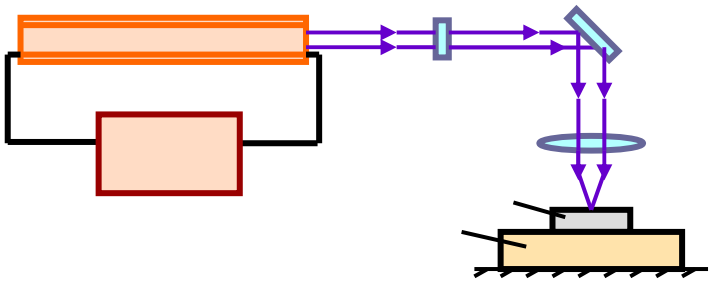

Fig. 1 The principle of laser engraving

Image processing is an important part of the laser engraving of the image, the image must be processed into that the laser engraving systems can identify the format. It's crucial in line with the characteristics of the laser engraving image processing methods, reasonable laser engraving process parameters.

Laser engraving characteristics and applications

Laser engraving characteristics

Laser has four major personalities : high brightness, high directivity, high pure, high coherence[2-5].Laser's personalities make laser engraving unique characteristics:

(1) non-contact processing, without special complex fixture, loss without tools, processing finished work without stress and deformation

(2) the minimum cut (CO_2 laser cutting slot < 0.5mm), improves the utilization rate of materials, material saving

(3) the accurate control, no inertia, high speed and in any position to start or stop processing

(4) the thermal deformation is small, the laser energy concentrated heat affected zone is very small, to prevent the heat diffusion of high speed machining.

Areas of laser engraving applications

In industry, lasers are used in four major processing areas:cutting,welding, marking and heat treatment. And laser carved of processing object also involves widely as organic board, cloth, paper, leather, rubber,various wood,intensive version, made bubble cotton, beauty resistance dish, glass, plastic, other non-metal,metal, ceramic, plastic,involves machinery industrial, steel industrial,ship industrial, car industrial, electronics,defense and people's life.

Study on the key technology of laser engraved image

Laser engraved image processing

An image is made up of red, green, and blue channels. According to the logarithmic relationship between white and black is divided into grades, image is divided into 256 levels of gray.Laser engraving is the density of points to reflect the outlines of pictures, a picture consistent with the characteristics of laser engraving gray image, higher resolution and clarity, better contrast ;

Fig.2 Raw image import software

(1)The original import Adobe Photo shop CS5 10.8MB pixel size, width 1456 pixels 2592 pixels high resolution 300 pixels/inch, click on the image-mode-gray(8 bits per channel) , initially gray, image pixels are calculated for 3.6MB at this time.

Fig. 3 Image gray preliminary processing

(2)Image bitmap output: 300 pixels/inch, halftone screen frequency 96 lines per inch, angle: 45 °, shape: round; output image pixel is important, characteristics of different materials is not set the parameters according to different materials and the results that you want to be, go through several tests, summarized the appropriate settings.

Fig. 4 Formation dotted gray bitmap processing

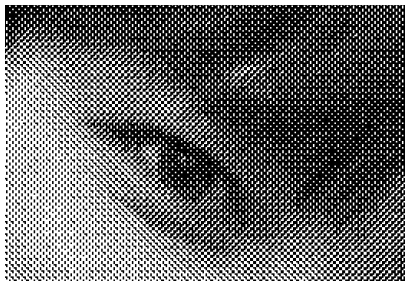

Fig.5 Local amplification effects

(3)Two times gray processing, according to the proportion of 1:1 output image, stored as *BMP format or JPEG format.

We can choose any bitmap as carved objects, but the laser itself condition is different, image processing parameter is different, finally carving effect will be very different[4]. Aiming at the character images, should pay attention to character outline clear process, characters and the background color and contrast, brightness.

Laser engraving technology

The performance of different materials, carving scheme adopted will be different. Engraving process parameters selection is the quality assurance of carving,there are many factors affect the quality of laser engraving, after repeated experiments, summarize the following points:

(1)Materials

Different materials absorb the energy different, lens together to the workpiece of laser energy can't all be absorbed.Thickness of carving, carving directions, materials, texture and other factors are taken into account.

(2)Laser ‘s output power

Laser’s output power and artifacts obtained by laser energy. When the focus is fixed on the workpiece surface, as the laser output power enhancement, carved by larger and deeper, carbonized black behavior occurs on the workpiece surface.

(3) The focal length focus on sculptured artifacts which form the shape of the pit depth has a major impact,.Engraving before experimenting prepare to determine the engraving effect, adjust the optimal focal distance to achieve the best engraving effect.

(4) Divergence angle of laser, engraving speed, exposure time, but due to the effect of carving power[2]

Professional engraving software Laser DRW will deal with image import, speed-carving speed: 180mm/s, carving the current: 14.2mA, carving area 90×90mm , engraving materials: 90mm paulownia in diameter wafers.

Fig. 6 Final carved effect

Cleaning the carbide processing

After engraving , use a damp cloth to clean the surface, charred parts available carbide surface oxidation and reduction of chemical materials and ultimately achieve bleaching effect, moderate concentrations of hydrogen peroxide.

Conclusion

Adoption of CO_2 laser carving on the paulownia color photo examples, discusses the key technologies of laser engraving the image. Expounded the principles and application of image processing technology, analysis of factors affecting the engraving effect, laser engraving and paulownia to find reasonable process parameter settings, provide technical support to ensure the quality of engraving is of great practical significance.

Study of PCM/FM Telemetry Sequence Soft Demodulation

Zhu Dongxu[1,a] , Fu Gang [1, a], and Feng Yue[1,a]

[1]China Satellite Maritime Tracking and Control Department, China
[a]348237548@sina.com

Keywords: synchronous, PCM/FM, MSD

Abstract. In order to improve the performance of PCM/FM signal demodulation system, this paper studies a kind of Symbol Detection more (Multi-Symbol Detection, MSD) technology. First for PCM/FM in hardware demodulation, a series of problems in the introduction of MSD software demodulation method; Then the MSD demodulation under low SNR synchronous implementation; The algorithm simulation, the results show that the bit error rate of 10^{-4}, detection performance than traditional non-coherent frequency discrimination algorithm can improve the nearly 3 dB, the performance is very ideal.

Introduction

With the rapid development of space technology, PCM/FM system get extensive application in the field of space remote sensing. In reference [1] proposed a method of using digital frequency demodulation realization of PCM/FM intermediate frequency signal demodulation, this demodulation method is helpful to reduce the error rate of signal demodulation, suitable for multi-stage assembly line's handling of the hardware, software radio processing platform is the most familiar demodulation method. And the use of software to realize signal processing has become the development trend of signal processing in the future.

The traditional discriminator is demodulation and detection for each symbol. For software demodulation, [2-3] and mentioned in the literature [4] using the short-time Fourier transform and instantaneous frequency measurement method for FM frequency estimation, thus the demodulating baseband signal. By further testing, short time Fourier transform method to the detection threshold improvement of bit error rate of 10^{-5} less than 3 dB, the instantaneous frequency measurement method when the signal-to-noise ratio is lower than 20 dB cannot achieve normal demodulation. This article in view of the traditional PCM/FM signal at low SNR is difficult to realize effective demodulation, symbol between before and after the combination of PCM/FM signal phase, the characteristics of the memory research a kind of method of demodulation and synchronization based on MSD.

1 The maximum likelihood algorithm of MSD

X for sending signals from the corresponding vector, r (t) for receiving signals, y for the receiver to receive signals of the verdict. Because of the symbol and noise are independent of each other, so are:

$$\begin{aligned} p(x/r(t)) &= p((x_1,x_2,\cdots,x_n)sent/(r_1,r_2,\cdots,r_n),n_r(t)) \\ &= \frac{p((x_1,x_2,\cdots,x_n)sent,(r_1,r_2,\cdots,r_n),n_r(t))}{p((r_1,r_2,\cdots,r_n),n_r(t))} \\ &= \frac{p((x_1,x_2,\cdots,x_n)sent,(r_1,r_2,\cdots,r_n))p(n_r(t))}{p((r_1,r_2,\cdots,r_n))p(n_r(t))} \\ &= p((x_1,x_2,\cdots,x_n)sent/(r_1,r_2,\cdots,r_n)) \\ &= p(x/r) \end{aligned} \quad (1)$$

Based on maximum a posteriori probability (MAP) criterion, observations of N symbols received conditional probability of r(t) are as follows:

$$p(r(t)/s(t),\theta)=\frac{1}{\sqrt{2\pi N_0}}\exp\{-\frac{1}{N_0}\int_{(n-N+1)T}^{(n+1)T}\left|r(t)-s(t)e^{j\theta}\right|^2 dt\} \quad (2)$$

To further simplify the above formula is:

$$p(r(t)/s(t),\theta)=Fe^{-NA^2T/N_0}\exp\{-\frac{1}{N_0}\int_{(n-N+1)T}^{(n+1)T}\left|r(t)\right|^2 dt\}\exp\{-\frac{2A}{N_0}\left|\beta\right|\cos(\xi-\arg\beta)\} \quad (3)$$

$$\beta=\int_{(n-N+1)T}^{(n-N+2)T}(r(t)e^{-j2\pi ha_{n-N+1}q(t-(n-N+1)T)})dt+e^{-j\pi ha_{n-N+1}}\times\int_{(n-N+2)T}^{(n-N+3)T}(r(t)e^{-j2\pi ha_{n-N+2}q(t-(n-N+2)T)})dt$$

$$+...+(\prod_{i=n-N+1}^{n-1}e^{-j\pi ha_i})\times\int_{nT}^{(n+1)T}(r(t)e^{-j2\pi ha_n q(t-nT)})dt \quad (4)$$

More symbol detection is to find the corresponding order, has absolute maximum likelihood. Detection algorithm is derived according to the many symbols, its implementation is shown in figure 1.

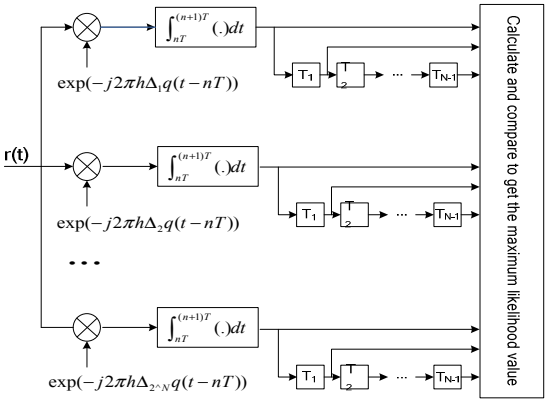

Fig1 Multiple symbol detection algorithm implementation block diagram

Further formula for computing the likelihood value is:

$$T_i=\sum_{n=1}^{N}\Gamma_{i_{n,N-n}}C_n \quad , \quad C_1=1 \quad , \quad C_k=\exp(-j\pi h\sum_{l=1}^{k-1}\Delta_{i_l})$$

2 Algorithm implementation process

Phase state transition diagram of PCM/FM signal can be expressed with grid, binary to the modulation index is equal to 0.5 PCM/FM signal, for example, the state grid as shown in figure 2, the abscissa for time, ordinate with phase.

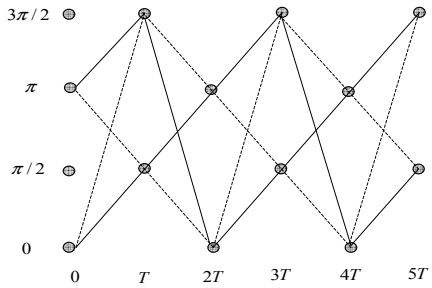

Fig2 h = 0.5 of PCM/FM signal phase grid figure

1, the t = 0 point set each state path metric is zero, the initial state is zero.

2, calculate all reach the measurement of the path. T = 3 t moment in figure 2, for example, a phase state of t = 3 t time for $s_3^{\pi/2}$, calculated from the time t = 0 to t = 3T time all reach the measurement of the path, a one-time completion of all of the metrics calculation, $s_1^{\pi/2}/s_0^0+s_2^0/s_1^{\pi/2}+s_3^{\pi/2}/s_2^0$, $s_1^{\pi/2}/s_0^0+s_2^{\pi}/s_1^{\pi/2}+s_3^{\pi/2}/s_2^{\pi}$, $s_1^{3\pi/2}/s_0^0+s_2^{\pi}/s_1^{3\pi/2}+s_3^{\pi/2}/s_2^{\pi}$, $s_1^{3\pi/2}/s_0^0+s_2^0/s_1^{3\pi/2}+s_3^{\pi/2}/s_2^0$.

3, screening and save the best path. Comparison in the previous step all reach the path measurement, the size of the selected measure minimum path, and save the path.
4, demodulation data obtained. To step on the best path to back the path through the element of $[x_{n-N},\cdots,x_{n-1},x_n]$, namely for the demodulation of the data.

3 Synchronization demodulation

Need to know the two symmetric points on either side of the maximum likelihood, can approximate a maximum likelihood to estimate the value of the frequency corresponding to the doppler frequency offset, and then to modify the signal carrier frequency, so as to eliminate the doppler frequency offset the impact on the decision. Figure 3 is a design using the curve fitting of the block diagram of corresponding frequency synchronization algorithm.

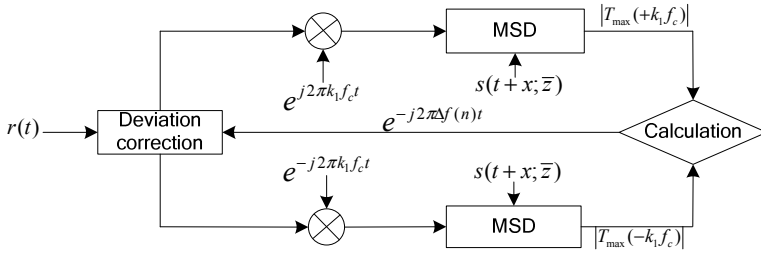

Fig3 Based on the MSD deviation compensation principle diagram

For after lifting the frequency of two-way signal to MSD after calculation, the two way likelihood value expressions for:

$$T_{\max}(\Delta f-\Delta f(n)+k_1f_c)=\max\{\int_0^{NT} r(t)e^{-j2\pi\Delta f(n)t}e^{j2\pi k_1f_ct}s(t+x;\bar{z})dt\}$$

$$T_{\max}(\Delta f-\Delta f(n)-k_1f_c)=\max\{\int_0^{NT} r(t)e^{-j2\pi\Delta f(n)t}e^{-j2\pi k_1f_ct}s(t+x;\bar{z})dt\}$$

The two likelihood value difference, is the measuring receiver frequency offset error metrics, and can feedback loop frequency deviation, the deviation correction to correct ring. Update deviation:

$$\Delta f(n+1)=\Delta f(n)-\frac{e(n)}{|e(n)|}\lambda$$

$$e(n)=T_{\max}(\Delta f-\Delta f(n)+k_1f_c)-T_{\max}(\Delta f-\Delta f(n)-k_1f_c)$$

4 Algorithm performance.

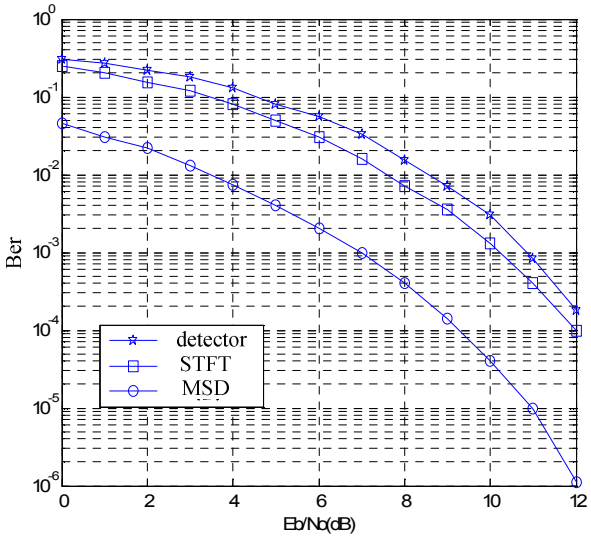

Fig4 Ber curve comparison diagram

Can be seen from the figure 4, the best method of MSD of demodulation, the bit error rate of 10^{-4}, compared to the noncoherent frequency demodulation can get about 3 db channel gain, performance is very ideal.

Summary

Study a relatively new FM signal demodulation technology, namely the MSD algorithm and the corresponding synchronization technology. Test results show that this method is illustrated in the aspect of improving channel gain performance advantages, make up for the low SNR telemetry signal demodulation error rate is higher, the shortcomings of traditional method of demodulation threshold and breakthrough. With the continuous development of software technology, PCM/FM software demodulation method based on MSD will have broad prospect of application.

Keywords: Reentry Telemetry, PCM/FM, Soft Demodulation

Abstract. PCM/FM system is one of the most widely used in the rocket telemetry system. Target spacecraft reentry telemetry telemetry signals in the process of low signal noise ratio (SNR), that the breakthrough tradition demodulation method of demodulation threshold problem, combined with the PCM/FM signal phase characteristic, the research based on a baseband complex rotating orthogonal symbol detection software (MSD) to solve method, and the corresponding synchronization algorithm is applied to ensure the smooth operation of the demodulation. The simulation and test results verified the soft demodulation algorithm can make the demodulation threshold effectively reduce.

Introduction

Remote sensing has a special channel is in the process of reentry telemetry channel, when the target aircraft on reentry telemetry channel, there are two main obstacles, namely again into the blackout and multipath effect. [1]Reentry black barrier is the main problem that bring on the aircraft surface to form certain thickness of the ionosphere, hinder the spread of the signal, the signal-to-noise ratio drops rapidly. And multipath effect, meaning that the channel is time-varying channel in the whole process of reentry telemetry from the sky to the ground, the channel parameters changed dramatically over time, the frequency spectrum of the received signal component will be subject to the influence of different gain level and nonlinear phase shift, that cause the receiving signal phase's serious distortion, bit error rate increased.

Above problem for PCM/FM telemetry signal demodulation method is selected to bring certain problems: in the low signal noise ratio (SNR), and complete normal demodulation signal distortion. This paper studies a demodulation method based on orthogonal complex baseband rotating MSD for PCM/FM telemetry signals under the environment of reentry telemetry demodulation. Similar to ordinary MSD, compared to the traditional non-coherent frequency demodulation method, to raise the channel gain nearly 3 dB[2], greatly reduces the threshold of PCM/FM telemetry signal demodulation. The simulation and test results verified the reentry telemetry channel environment effectiveness of the method.

1 Channel Model

In reentry telemetry channel, because the influence factors, such as multipath and platform of relative movement makes the mobile channel to transmit the signal in time, frequency and Angle caused the dispersion, so the multipath channel envelope statistical properties become the focus of our research. According to the statistical properties of different fading channel, the received signal envelope and several typical distributed generally, such as Rayleigh distribution, Rice distribution and the Nakagami -m distribution. In this paper, in accordance with Rayleigh distribution as a background for the multipath channel simulation.

Discrete multipath fading channel model is:[3]

$$R(t) = \sum_{k=1}^{N(t)} r_k(t) s_{FM}(t - \tau_k) \tag{1}$$

In order to show the multipath effect on telemetry signals, the Rayleigh channel characteristics, and through the Rayleigh channel of PCM/FM signal time-frequency characteristics of MATLAB

as shown in figure 1. Simulation conditions: the decline of path set to 6, intermediate frequency 70 MHz PCM/FM signal, code rate 2 Mbps, sampling rate and 56MSPS installed base, modulation index was 0.7.

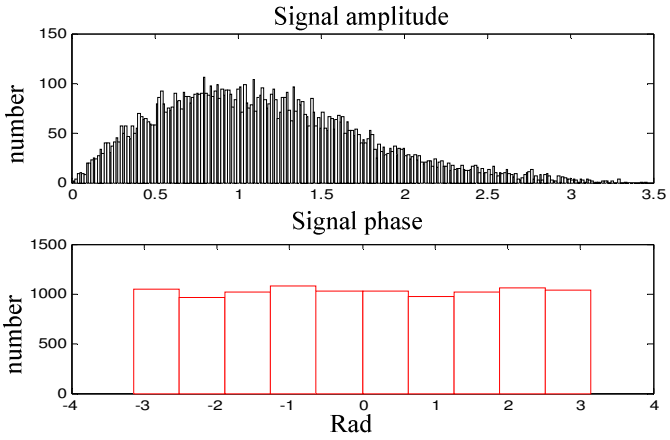

Fig1 Signal under the effect of Rayleigh channel amplitude and phase distribution

From figure 1, you can see, the received signal envelope obey Rayleigh distribution, phase in (0 ~ 2π) obey uniform distribution.Which conform to the Rayleigh distribution channel model.

2 Baseband complex rotating orthogonal MSD algorithm

Set the remote sensing observation period received can simplify the intermediate frequency signal is expressed as:

$$s(t)=\cos[w_c+f(t)+\theta_1] \tag{2}$$

Using the orthogonal digital frequency conversion technology to deal with $s(t)$, the received signal with local orthogonal carrier multiplication, respectively after the Hilbert transform of two orthogonal baseband signals (I/Q) :

$$I=\cos[f(t)+\theta_1] \tag{3}$$

$$Q=-\sin[f(t)+\theta_1] \tag{4}$$

When a local element combination and the received signal element phase at the same time, after two baseband signal resulting from the multiplication form of complex signals in the observation time remain the same. And when local other element combination of baseband after signal and the received after signal multiplication, the complex signals always changing.

According to the code rate and sampling rate can be observed within the length of the sampling points, set to N_C, the result of the product in integral operation, within the length of observation are:

$$M=N_C\cdot I_B+jN_C\cdot Q_B \tag{5}$$

Results modulus square, get:

$$S=N_C{}^2\cdot(I_B{}^2+Q_B{}^2) \tag{6}$$

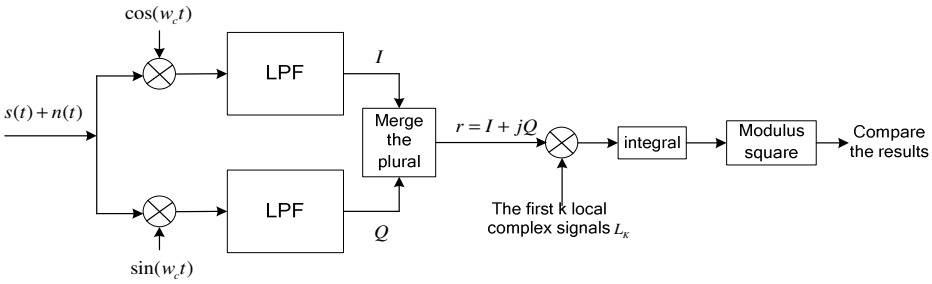

Fig2 Baseband orthogonal MSD principle block diagram

In figure 3 is only part of the local element corresponding to a group of complex signal and receiving orthogonal complex baseband signal block diagram of the baseband orthogonal MSD

decision, other local signal and received signal processing is similar, all is through relevant square to compare the result of the decision.

This more than symbols of orthogonal complex baseband signal detection, because of the baseband signal frequency is low, so the requirements of the processing speed is low, is advantageous to the computer software processing. But in terms of computational burden, there is still no fell, the intermediate frequency more casual and symbol detection algorithm is basically the same. So on this basis, the introduction of the complex spinning technology, namely the integral in a bit, then through after the way to realize the symbol detection, thus reduce the amount of calculation.

In a row in table 1 code sequences, on both sides of the two values are said to be on the current element before and after the disturbance of two element. Through the above analysis, the local can generate the initial phase element corresponding to the baseband signal $L_1, L_2, \cdots, L_8$. The 8 kinds of signal is the difference between the length of time is only one element width, and the eight kind of signal is a baseband modulation signal. A similar method respectively to the current received orthogonal complex baseband signal correlation processing in a symbolic, get eight plural $M_{10}(1), M_{20}(1), \cdots, M_{80}(1)$.

Table 1 Element combination and the corresponding phase

number	(1)	(2)	(3)	(4)
symbol sequence	-1 -1 -1	-1 -1 +1	+1 -1 -1	+1 -1 +1
corresponding phase	-0.7π	-0.58π	-0.58π	-0.47π
number	(5)	(6)	(7)	(8)
symbol sequence	+1 +1 +1	+1 +1 -1	-1 +1 +1	-1 +1 -1
corresponding phase	0.7π	0.58π	0.58π	0.47π

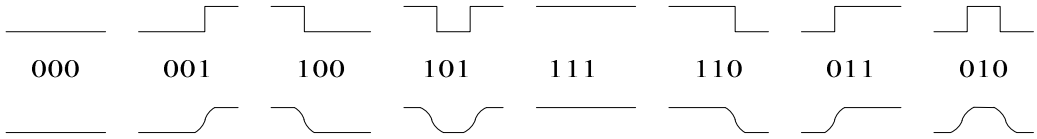

Fig3 Preset filter before and after eight possible code waveform comparison

Assume element observation length N = 5, 128 in observation length can be the local signal, and because the local signal phase change in the length of 5 yards yuan continuity, calculate the local 128 signals of each within the first four element length of the initial phase of local signal, can calculate the L_1 to L_8 may be the initial phase of the 8 kinds of local signal. Eight of the plural by allowing for $M_{10}(1)$ to $M_{80}(1)$ accordingly plural Angle rotation, get eight different symbol waveform corresponding to different initial phase values of local signal associated with the current signals as a result, $M_{11}(1), \cdots, M_{1p}(1), M_{21}(1), \cdots, M_{2p}(1), M_{81}(1), \cdots, M_{8p}(1)$.

According to the current element time of various local corresponding correlation matching value of the received signal waveform and $M_{10}(1)$ and $M_{80}(1)$ and before 4 yards yuan period have different code to local waveform and the initial phase of the correlation value between the received signal $M_{10}(k), \cdots, M_{1p}(k), M_{20}(k), \cdots, M_{2p}(k), M_{80}(k), \cdots, M_{8p}(k)$ $(k = 2,3,4,5)$ .Out of the 128 possible, recent five yards yuan period of approximate correlation value. Both before and after, for example, consider the symbol sequence element, the influence of length, we assume that the observation of element within the local signal sequence is -1+1+1-1-1-1+1 (the last but one to the current element), rotating through compounding technology and accumulation process, will be able to get this kind of circumstance the five element was used to observe the relative value in the length, expressed as:

$$M_n = M_{7a}(5) + M_{6a}(4) + M_{3c}(3) + M_{1d}(2) + M_{20}(1) \tag{10}$$

Among them a, b, c, d values range from 1 to P. Then to receive signal and local signal to calculate the complex signal, a total of 128 square arithmetic, then compare the verdict, get the final demodulation element.

3 Simulation result

In the baseband after rotating orthogonal MSD demodulation process on the basis of overall study, the following will be under the reentry telemetry channel environment, the parameters in the simulation according to the telemetry standard manual produce PCM/FM telemetry signals, using normalized SNR E_b/N_0 as main parameters, analysis of the BER and MSD demodulation and statistics, in the end, and then with traditional non-coherent frequency demodulation method[4] and short-time Fourier method demodulation performance comparison, the result is shown in figure 4.

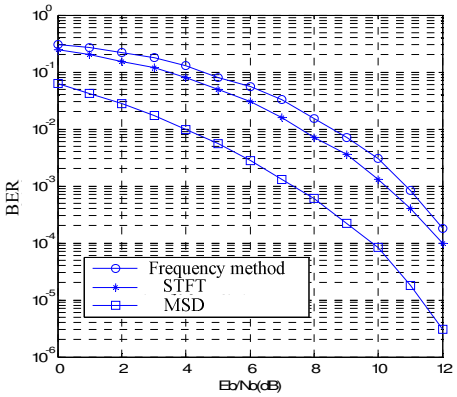

Fig4 Ber curve comparison chart

Can be seen from figure 4, MSD demodulation method of ber performance is much better than that of short time Fourier method and the traditional non-coherent frequency demodulation method. Compared to the traditional non-coherent frequency discrimination method, baseband complex rotating orthogonal MSD method can get the channel gain of about 2.4 dB.

Summary

Study a baseband complex rotating orthogonal MSD algorithm: first, the intermediate frequency PCM/FM signal under the digital frequency conversion processing, get the same phase and orthogonal subgrade with two orthogonal signal, again to two orthogonal signals in an integral element, and then through the complex spinning technology to compare with the size of integral value of the local signal to realize signal demodulation. Based on the MATLAB language to realize the demodulation system, under the environment of reentry telemetry channel, according to the telemetry standards manual test the simulation signal and the demodulation system. Test results show that this method can effectively solve the reentry telemetry environment SNR break the traditional problem of demodulation method of threshold. The reentry remote sensing signal demodulation has a certain reference significance.

Keywords: Virtual Radio, PCM/FM, STFT

Abstract. According to the characteristics of PCM / FM signals, we propose a new method based on STFT resolve tune software. Firstly, the spectral characteristics of PCM / FM signal is given use of the spectrum PCM / FM signal is demodulated theoretical basis. This paper discusses in detail the basic principles of this demodulation method and implementation process, analyze the demodulation performance and complexity of the method.

Introduction

PCM / FM signal is the current data transmission system is widely used as a signal type. Since the actual received PCM / FM signals and more non-stationary random signal, non-stationary random signal processing usually time-frequency analysis method. [1][2] proposed STFT and WD-based FM signal demodulation method has strong anti-noise and anti-fading, but the larger amount of computation, is not conducive to the realization of real-time processing software. With the continuous improvement of the performance of general-purpose computing, software-based radios (Software Define Radio-SDR) technology, signal processing modes are gradually departing from the dedicated hardware platforms (such as DSP or FPGA), digital signal A / D after the general-purpose computer on the platform, the signal "pure software" of the real-time processing by the application.

1 PCM / FM signal spectral characterization

PCM / FM telemetry signal field called continuous phase frequency shift keying (CPFSK) signal, the modulation method is the use of high frequency carrier moves to the first symbol representing a binary "1" state, moved to the second lower represents the frequency of the carrier wave binary symbol "0" state. Therefore, PCM / FM signals within one symbol can be regarded as the width of a single sinusoidal carrier frequency signals, by alternating two different carrier frequencies, digital data "0" "1" and transmission.

In a code width PCM / FM signal may be expressed as:

$$x(n) = A\exp[\ j(2\pi f_i n + \varphi)] + z(n) \qquad (n = 0,1,\cdots,N_w - 1) \tag{1}$$

And can be expressed as the formula $X = A_c E + Z$.

Among them,

$$\begin{cases} X = [x(0) \quad x(1) \quad \cdots \quad x(N_w - 1)]^T \\ E = [\quad 1 \quad e^{j2\pi f_i} \cdots \quad e^{j(N_w-1)2\pi f_i}\ ]^T \\ Z = [z(0) \quad z(1) \quad \cdots \quad z(N_w - 1)]^T \end{cases} \tag{2}$$

$$A_c = A\exp(j\varphi)$$

X signal A_c is obtained by the maximum likelihood (MLE) is estimated:

$$\hat{A}_c = \frac{E^H R_z^{-1} X}{E^H R_z^{-1} E} \tag{3}$$

And this estimate is unbiased.

$R_z = \sigma^2 I$ substituted into the formula (3) we have:

$$\hat{A}_c = \frac{E^H X}{E^H E} = \frac{1}{N_w} \sum_{n=0}^{N_w-1} x(n) e^{-j2\pi f_i n} \tag{4}$$

$\hat{A}_c$ is the amplitude of the signal amplitude A Unbiased MLE estimates.

$$A = \left| \hat{A}_c \right| = \frac{E^H X}{E^H E} = \frac{1}{N_w} \left| \sum_{n=0}^{N_w-1} x(n) e^{-j2\pi f_i n} \right| \tag{5}$$

So calculate the amplitude X signal f_0 / f_s, and f_1 / f_s as follows:

$$\begin{cases} a = \left| \dfrac{1}{N_w} \displaystyle\sum_{n=0}^{N_w-1} x(n) e^{-j2\pi (f_0 / f_s) n} \right| \\ b = \left| \dfrac{1}{N_w} \displaystyle\sum_{n=0}^{N_w-1} x(n) e^{-j2\pi (f_1 / f_s) n} \right| \end{cases} \tag{6}$$

In summary, according to the spectral characteristics of PCM / FM signal, the DFT method can be used by comparing the size of the amplitude of two frequency and demodulate the PCM / FM signal.

2 STFT demodulation method

Under the actual circumstances of the received PCM / FM signal is non-stationary random signal, the amplitude of DFT calculations cannot be used directly in a signal frequency point. Using short-time Fourier transform (STFT) method, the use of relatively narrow width of the window function for the interception of a time-domain signal, the signal thus obtained can be regarded as stable, and then the DFT. If you let the window function along the time axis signal continuously moving, you can get PCM / FM signals in two frequency energy over time, the process of change. PCM / FM signal using the signal frequency changes the transmission of digital information, you can compare the two by size variation frequency energy to achieve the demodulated signal. The length of the time window within the sampling points should be close to a symbol, it is a good frequency energy accumulation, improving the performance of signal demodulation.

$x(n)(n = 0,1,\cdots, N-1)$ DFT is defined as:

$$X(k) = \sum_{n=0}^{N-1} x(n) e^{-j\frac{2\pi}{N} nk} \qquad (\text{k=0,1,….N-1}) \tag{7}$$

The classic definition of DFT only an integer k, and if the test frequency does not correspond to integer values of k can be obtained from the amplitude of the frequency on the nearest integer k, which is the measured frequency energy Sinc function is not a peak, but rather a value near the peak, which affects the demodulation performance. To obtain the peak Sinc function, k is used when the DFT fraction, which corresponds to the first windowed taken after zero padding data, and then make DFT, which is equivalent to the interpolation in the frequency domain or the frequency domain is reduced when the discrete sampling interval.

$$x'(n) = \begin{cases} x(n), & n = 0,1,\ldots N-1 \\ 0, & n = N, N+1,\ldots rN-1 \end{cases} \tag{8}$$

$$X'(k) = \sum_{n=0}^{rN-1} x'(n) e^{-j\frac{2\pi}{rN} nk} = \sum_{n=0}^{N-1} x(n) e^{-j\frac{2\pi k}{N r} n} \tag{9}$$

Because of the increased sample values is zero, so does not greatly increase the amount of calculation. Calculation of energy and only a single frequency, greatly reducing the amount of calculation STFT. At this frequency is calculated by STFT energy by the formula f_i:

$$STFT_x(n, k_i) = \sum_{M=0}^{M-1} \tilde{x}(m, n) e^{-j\frac{2\pi}{M} k_i m} \qquad (k_i = M * f_i / f_s) \tag{10}$$

Among, $M = rN$, $\tilde{x}(m,n) = x(m) \cdot W(n-m)$.

Thus, a sequence of length N can be decomposed into operation DSTFT 1×N data vector with N×1 rotation coefficient vector, a calculation amount for the N complex multiplications, (N-1) complex additions. To further reduce the amount of computation processing can be used for the rectangular window DSTFT recursion method, see the derivation of equation (11). When the next DSTFT, you can use the results of the previous conduct DSTFT, greatly reducing the amount of computation. During the sliding of the rectangular window, for each quantitative calculation DSTFT 2 complex multiplications and two complex additions.

$$
\begin{aligned}
&DSTFT(n+1,\omega) = \sum_{m=0}^{M-1} x(n+1+m)e^{-j\omega m} \\
&= \sum_{m=1}^{M} x(n+m)e^{-j\omega(m-1)} \\
&= e^{j\omega}\sum_{m=1}^{M-1} x(n+m)e^{-j\omega m} + x(n+M)e^{-j\omega(M-1)} \\
&= e^{j\omega}\left(\sum_{m=0}^{M-1} x(n+m)e^{-j\omega m} - x(n)e^{-j0}\right) + x(n+M)e^{-j\omega(M-1)} \\
&= e^{j\omega}[STFT(n,\omega) - x(n)] + x(n+M)e^{-j\omega(M-1)}
\end{aligned}
$$

3 Algorithm performance.

Spectral energy calculated by STFT 0,1 frequency signal is:

$$
\begin{aligned}
a^2 &= \left| A\sum_{n=0}^{N_w-1} e^{j[2\pi(f_0/f_s)n+\varphi]} \cdot e^{-j2\pi(f_0/f_s)n} \right|^2 \\
&= \left| AN_w e^{j\varphi} \right|^2 = A^2 \cdot {N_w}^2 \qquad (11)
\end{aligned}
$$

$$
b^2 = \left| A\sum_{n=0}^{N_w-1} e^{j[2\pi(f_0/f_s)n+\varphi]} \cdot e^{-j2\pi(f_1/f_s)n} \right|^2 \qquad (12)
$$

$$
\Delta f = (f_1 - f_0)/f_s = 2K_{FM} \times R_b / f_s \qquad b^2 = A^2 \cdot \left| \frac{1-e^{j2\pi N_w \Delta f}}{1-e^{j2\pi\Delta f}} \right|^2 = A^2 \cdot \frac{1-\cos 2\pi N_w \Delta f}{1-\cos 2\pi\Delta f}
$$

$$
\rho_0 = \frac{b^2}{a^2} = \frac{1-\cos 2\pi N_w \Delta f}{{N_w}^2(1-\cos 2\pi\Delta f)} = \frac{\sin^2 N_w \dfrac{\Delta\omega}{2}}{{N_w}^2 \sin^2 \dfrac{\Delta\omega}{2}} \qquad (13)
$$

The relationship between ρ_0 and $\Delta\omega$ shown in Figure 1.

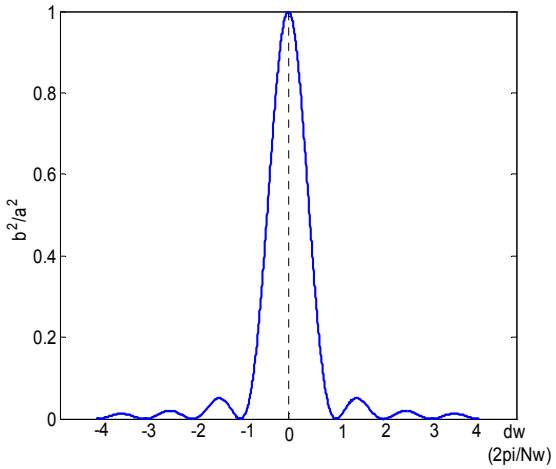

Fig 1 The relationship between ρ_0 and $\Delta\omega$

The relationship between ρ_1 and $\Delta\omega$ shown in Figure 2.

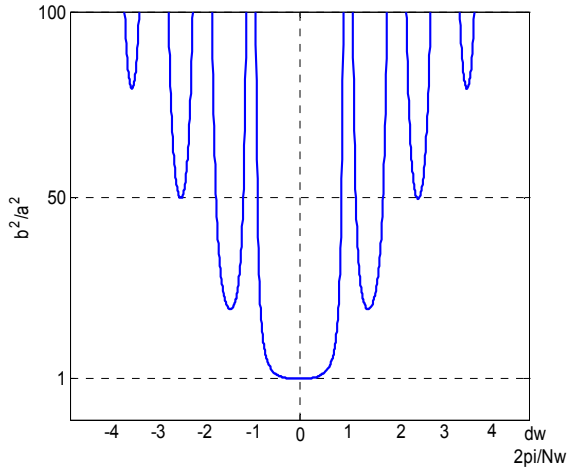

Fig 2 The relationship between ρ_1 and $\Delta\omega$

It can be seen that when the constant frequency offset PCM / FM signals, a method using STFT demodulating the best performance.

Summary

By comparing the two changes in the size and frequency energy law, the realization of the demodulated signal. Through the truncated data zeros ways to improve the impact of the barrier effect STFT window function brings the calculation frequency energy.

Keywords: Chirp signal, FRFT, adaptive filter

Abstract. In this paper, an adaptive filter method for Chirp signal in additional white Gaussian noise (AWGN) is studied. First, we analyze conception and character of FRFT (Fractional Fourier Transform), and the results shows that Chirp signal has energy concentration character in FRFT domain. Then, an adaptive filtering method is introduced in FRFT domain, and a test is done for separating Chirp signal from AWGN by the filtering method. Last, performance of this filtering method is studied, and the SNR improvement expression is concluded to verifying its advantages, it depends on the performance of adaptive filter basically. At last, the results show that this filtering algorithm is simple in computation and easy in implementation.

Introduction

Chirp signal is a kind of non-stationary signal, it is applied in radar, sonar and communications widely. Hereby, it is important works to process Chirp signal in modern signal processing, where the shoe pinches is to rebuild Chirp signal from the polluted signal by noise, this problem can be concluded as the polluted signal filtering or wave form estimation essentially. We can use spectral line enhancement technique to improve SNR of sinusoid signal in AWGN, and the key part of this technique is adaptive filter.

Recent years, Fractional Fourier transform (FRFT) gained a lot of attention as a new time-frequency transform tool. It is put forward by V.Namias [1] and applied in non-stationary signal processing area. FRFT represents time-frequency distribution of a signal with a single variable and has no cross-term problem; hence, it is much well suitable to process non-stationary signal especially chirp-like signals. Some scholars proposed time-frequency filtering based on FRFT during the past years [2], and the FRFT domain filtering algorithm was ulterior consummated subsequently[3]. In this paper, an adaptive time-frequency filtering algorithm of Chirp signal based on FRFT is proposed to restrain noise.

1 Fractional Fourier transform

FRFT is generalization of Fourier transform (FT) with an order, and it is a one-parameter subclass of linear transform. The FRFT of $x(t)$ is defined as

$$X_p(u)=\left\{\mathcal{F}^p[x(t)]\right\}(u)=\int_{-\infty}^{+\infty}K_p(u,t)x(t)dt,\quad 0<|p|<2,0<|\alpha|<\pi$$
$$=\begin{cases}B_\alpha\int_{-\infty}^{+\infty}\exp\left(j\dfrac{t^2+u^2}{2}\cot\alpha-\dfrac{jtu}{\sin\alpha}\right)x(t)dt, & \alpha\neq n\pi\\ x(t) & \alpha=2n\pi\\ x(-t) & \alpha=(2n\pm1)\pi\end{cases}\tag{1}$$

Where $\mathcal{F}^p[.]$, $K_p(u,t)$, p, u and $\alpha=p\pi/2$ are the FRFT operator, kernel function, FRFT order, FRFT domain and rotation angle respectively, and coefficient $B_\alpha=\sqrt{(1-j\cot\alpha)\pi/2}$.

According to formula (1), we can easily know that the inverse FRFT can be defined as

$$x(t)=\mathcal{F}_{-p}[X_p(u)](t)=\int_{-\infty}^{+\infty}X_p(u)K_{-p}(t,u)du\tag{2}$$

Obviously, FRFT can be interpreted as a rotation in the time-frequency domain, and it can be also viewed as chirp-basis expansion according to formula (2). Therefore, FRFT is also called angular Fourier transform or rotational Fourier transform in some documents [4].

2 Chirp signal in FRFT domain

In this section, we analyze the impulsive characteristic of Chirp signal in FRFT domain. A general expression of Chirp signal is defined as

$$s(t) = A \cdot \exp[j(2\pi f_0 t + k\pi t^2 + \varphi_0)],\ T/2 < t < -T/2 \tag{3}$$

Where, A, f_0, k, φ_0 and T is Chirp signal parameters of amplitude, initial frequency, Chirp rate, initial phase and time duration.

We have noticed that a time limited chirp signal had energy concentrated in a certain FRFT domain. By applying equation (3) to equation (1), FRFT of Chirp signal is

$$\begin{aligned} \mathcal{F}^p[s(t)] &= A\sqrt{1-j\cot\alpha}\int_{-\infty}^{+\infty} e^{\left(j\pi(t^2\cot\alpha - 2ut\csc\alpha + u^2\cot\alpha)\right)} e^{\left(j(2\pi f_0 t + \pi k t^2 + \varphi_0)\right)} dt \\ &= A\sqrt{1-j\cot\alpha}\, e^{j(\pi u^2\cot\alpha + \varphi_0)} \int_{-T/2}^{T/2} e^{\left(j\pi t^2(\cot\alpha + k)\right)} e^{\left(j2\pi t(f_0 - u\csc\alpha)\right)} dt \end{aligned} \tag{4}$$

Evidently, when $k = -\cot\alpha$, $f_0 = u\csc\alpha$, the transformed result will gain the maximum value.

3 FRFT domain filtering

If the tested signal is Chirp signal polluted by AWGN, and it is expressed as

$$x(t) = s(t) + n(t) \tag{5}$$

Where $s(t)$ is time duration limited Chirp signal and shown as $s(t) = A\exp[j(2\pi f_0 t + k\pi t^2 + \varphi_0)],\ T/2 < t < -T/2$, $n(t)$ is AWGN.

According to equation (4), we know that Chirp signal will be transformed to a impulsive function in FRFT domain when the Chirp rate $k = -\cot\alpha$, the amplitude of Chirp signal in FRFT domain reach the peak at that time. Therefore, a Chirp signal with specified Chirp rate will produces energy concentration phenomenon in a specified FRFT domain, and Chirp signal with different Chirp rate will gather energy in different FRFT domain, the FRFT order p_0 correspond to its Chirp rate is called optimal FRFT order. The relationship between Chirp rate and optimal FRFT order theoretically can be expressed as

$$p_0 = 2arc\cot(k)/\pi \tag{6}$$

However, no mater what FRFT order are, the transforming results still be noise and never gather energy. Therefore, the work of extracting Chirp signal in AWGN can be instead of adaptive filtering of sinusoid wave in AWGN.

According to the description above, diagram of an adaptive filtering algorithm based on FRFT is shown as figure (1).

Fig.1 Adaptive filtering algorithm based on FRFT

The step of the adaptive filtering algorithm can be divided into four steps as follow

Step 1: calculate the optimal FRFT order of the specified Chirp signal according to equation (6), and do FRFT for the polluted Chirp signal;

Step 2: compute position of the energy concentration peak in optimal FRFT domain according to formula $u_0 = f_0\csc(arc\cot(k)/\pi)$ based on relationship between FRFT and Wigner distribution;

Step 3: pass a designed adaptive filter to do covering peak processing center with u_0 in the optimal FRFT domain;

Step 4: do order of $-p_0$ FRFT for the Chirp signal after passing adaptive filter, and transform it back to time domain Chirp signal.

In order to validate validity of the adaptive filtering algorithm, we do MATLAB experiment for the algorithm. Parameters of the Chirp signal are set as: amplitude A is equal to 1V，initial frequency f_0 is 30Hz, Chirp rate k is set to be 100Hz per second, initial phase is 0, time duration is 1 second, sample frequency is 6000Hz and SNR=-3dB.

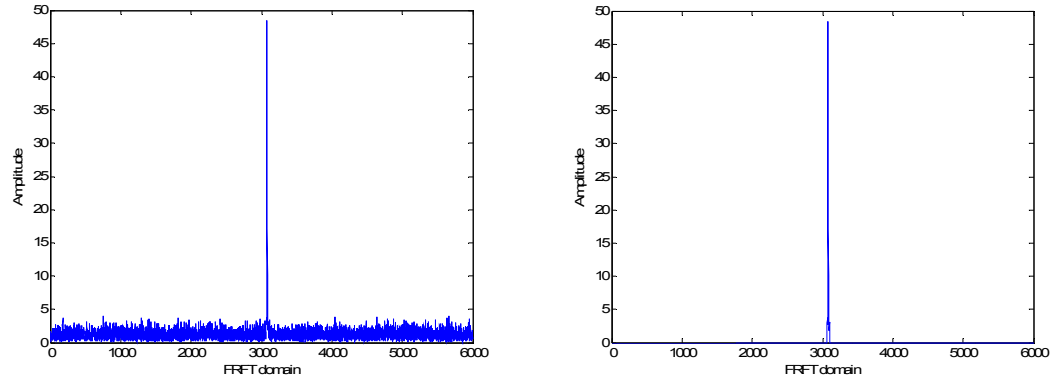

Fig. 3 Signal wave in its optimal FRFT domain before FRFT filtering and after FRFT filtering

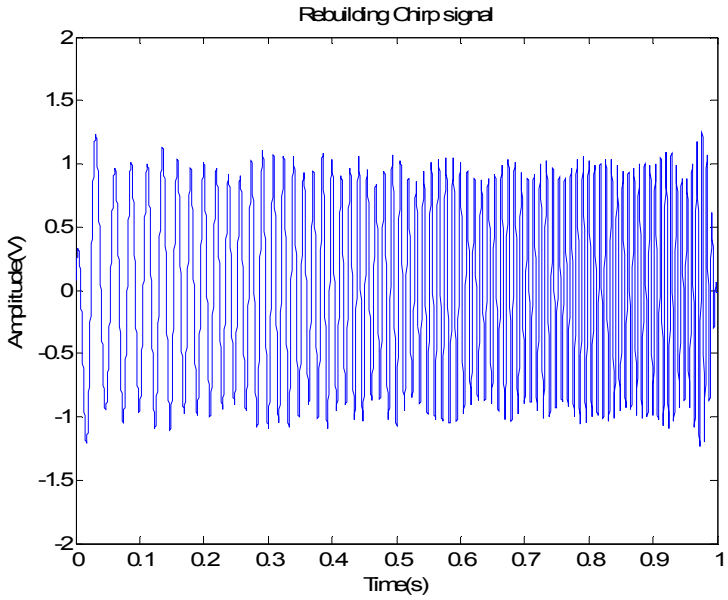

Fig.4 The rebuilding Chirp signal produced by FRFT domain filtering

5 Performance analyses

The complexity of Chirp signal adaptive filtering algorithm in this paper depends on the discrete FRFT algorithm, and there is several kind of fast algorithm corresponding to the discrete FRFT algorithm. Here, we select fast algorithm of discrete FRFT proposed by H.M.Ozaktas[4], and its computation complexity is equal to $O(N \lg N)$.

The effect of the filtering algorithm can be described by factor of SNR improving; it is defined as rate of the SNR before filtering and the SNR after filtering.

$$IF = \frac{SNR_{out}}{SNR_{in}} \tag{7}$$

After some approximately and series of complex computation, Qi Lin concluded that the expression of SNR improving factor IF can be described as [5]

$$IF = \frac{SNR_{out}}{SNR_{in}} \approx \frac{N}{\Delta n} \tag{8}$$

Where N is length of tested signal, Δn is bandwidth of band-pass filter in the optimal FRFT domain.

Summary

The aim of this paper is to propose an adaptive method for filtering Chirp signal embedded in AWGN. The idea that FRFT for a signal is equivalent to rotating the signal on time-frequency plane is used. First, a noisy Chirp signal rotated to a certain angle by FRFT will result in the least spectrum overlap between the signal and noise energy. Then, on the basis of dechirping the Chirp signal, a narrowband filter is exploited to extract the signal and depress most of the noise energy. Finally, the denoised Chirp signal is rotated back to the time domain using an inverse FRFT. Performance of the proposed method is seen through its simplicity in computation and in their improvement SNR.

Keywords: maximum likelihood, PCM/FM, MSD, variable step length synchronization

Abstract. Aimed at the problem that the demodulation threshold of non-coherent demodulation technology of PCM/FM telemetry system using frequency modulation in the present situation of aerospace measurement and control is higher, research a kind of multiple symbol detection based on maximum likelihood thought (Multi-Symbol Detection, MSD) demodulation method. This paper introduces the principle of multiple symbol detection and aiming at the shortcomings of the previous synchronization method, studies a kind of symbol decision process and synchronization of the combination of synchronization method.

Introduction

At present our country aerospace measurement range rocket telemetry system mainly USES the noncoherent frequency discrimination method, because do not need coherent signal at the receiving end, thus is widely used. [1]But its drawback is that the band pass filter demodulation threshold to demand higher and higher, the threshold effect. As more and more electromagnetic interference, and the function of the spacecraft distance increasing, this method will no longer apply. In order to improve the performance of PCM/FM signal demodulation, American Nova Eng. Inc., the company in recent years has been studying a technology: more symbol detection (MSD), and successfully applying it to PCM/FM telemetry system, obtained the channel gain of nearly 3dB. [2]

1 Baseband complex rotating orthogonal MSD algorithm

Baseband complex rotating orthogonal MSD algorithm

$$s(t) = \cos[2f_c t + f(t) + \theta_1] \tag{1}$$

Orthogonal signal after frequency conversion components, constitute a complex baseband signal, the form of the complex signal for:

$$R = I + j.Q = \cos[f(t) + \theta_1] - j\sin[f(t) + \theta_1] \tag{2}$$

With exactly the same receiving signal elements that local signal can be represented as:

$$L = \cos[f(t) + \theta_2] + j\sin[f(t) + \theta_2] \tag{3}$$

$$\begin{aligned} R \cdot L &= \cos(\theta_2 - \theta_1) + j\sin(\theta_2 - \theta_1) \\ &= I_B + jQ_B \end{aligned} \tag{4}$$

In the result of the type (4) the product of the integral operation within the length of observation are:

$$M = N_C \cdot I_B + jN_C \cdot Q_B \tag{5}$$

$$S = N_C{}^2 \cdot (I_B{}^2 + Q_B{}^2) \tag{6}$$

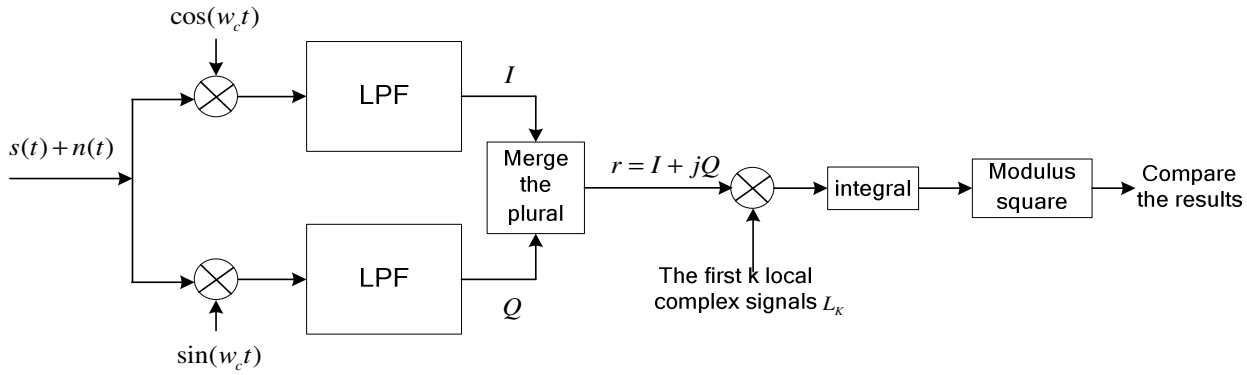

Fig1 Baseband orthogonal MSD principle block diagram

In a row in table 1 code sequences, on both sides of the two values are said to be on the current element before and after the disturbance of two element. Through the above analysis, the local can generate the initial phase element corresponding to the baseband signal $L_1, L_2, \cdots, L_8$. The 8 kinds of signal is the difference between the length of time is only one element width, and the eight kind of signal is a baseband modulation signal. A similar method respectively to the current received orthogonal complex baseband signal correlation processing in a symbolic, get eight plural $M_{10}(1), M_{20}(1), \cdots, M_{80}(1)$.

Table 1 Element combination and the corresponding phase

number	（1）	（2）	（3）	（4）
symbol sequence	-1 -1 -1	-1 -1 +1	+1 -1 -1	+1 -1 +1
corresponding phase	-0.7π	-0.58π	-0.58π	-0.47π
number	（5）	（6）	（7）	（8）
symbol sequence	+1 +1 +1	+1 +1 -1	-1 +1 +1	-1 +1 -1
corresponding phase	0.7π	0.58π	0.58π	0.47π

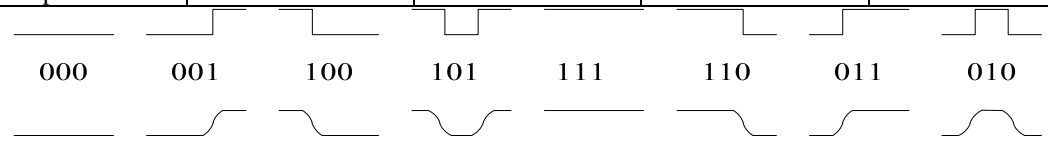

Fig2 Preset filter before and after eight possible code waveform comparison

Assume element observation length N = 5, 128 in observation length can be the local signal, and because the local signal phase change in the length of 5 codes continuity, calculate the local 128 signals of each within the first four element length of the initial phase of local signal, can calculate the L_1 to L_8 may be the initial phase of the 8 kinds of local signal. Eight of the plural by allowing for $M_{10}(1)$ to $M_{80}(1)$ accordingly plural Angle rotation, get eight different symbol waveform corresponding to different initial phase values of local signal associated with the current signals as a result, $M_{11}(1), \cdots, M_{1p}(1), M_{21}(1), \cdots, M_{2p}(1), M_{81}(1), \cdots, M_{8p}(1)$.

According to the current element time of various local corresponding correlation matching value of the received signal waveform and $M_{10}(1)$ and $M_{80}(1)$ and before 4 codes period have different code to local waveform and the initial phase of the correlation value between the received signal $M_{10}(k), \cdots, M_{1p}(k), M_{20}(k), \cdots, M_{2p}(k), M_{80}(k), \cdots, M_{8p}(k)$ $(k = 2,3,4,5)$ .Both before and after, for example, consider the symbol sequence element, the influence of length, we assume that the observation of element within the local signal sequence is -1+1+1-1-1-1+1 (the last but one to the current element), rotating through compounding technology and accumulation process, will be able to get this kind of circumstance the five element was used to observe the relative value in the length, expressed as:

$$M_n = M_{7a}(5) + M_{6a}(4) + M_{3c}(3) + M_{1d}(2) + M_{20}(1) \tag{10}$$

2 Synchronization variable step length

To step the same staircase tracking a sine wave as an example, as shown in figure 3.From top to bottom in turn for step size is too small, moderate step length, step size is too large. When the step length through the hours, means that the adjustment speed too slow, led to the capture time is too long. And when the amount being tracked changes fast, too slow adjustment speed can't timely tracking input, the tracking error is too big lead to can't really lock.

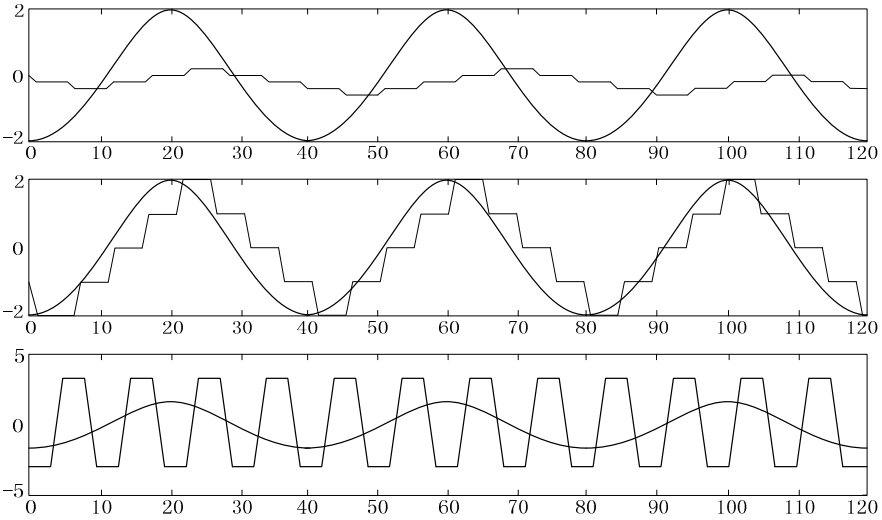

Fig3 Fixed step length schematic capture step speed, accuracy and long relationship

In order to improve the capture speed, the capture phase using larger iteration step length, inspired by speech signal delta modulation mode, designed the iteration step length controlled by the test statistic characteristics of the overall implementation scheme. The step length adjustment process as shown in figure 4.

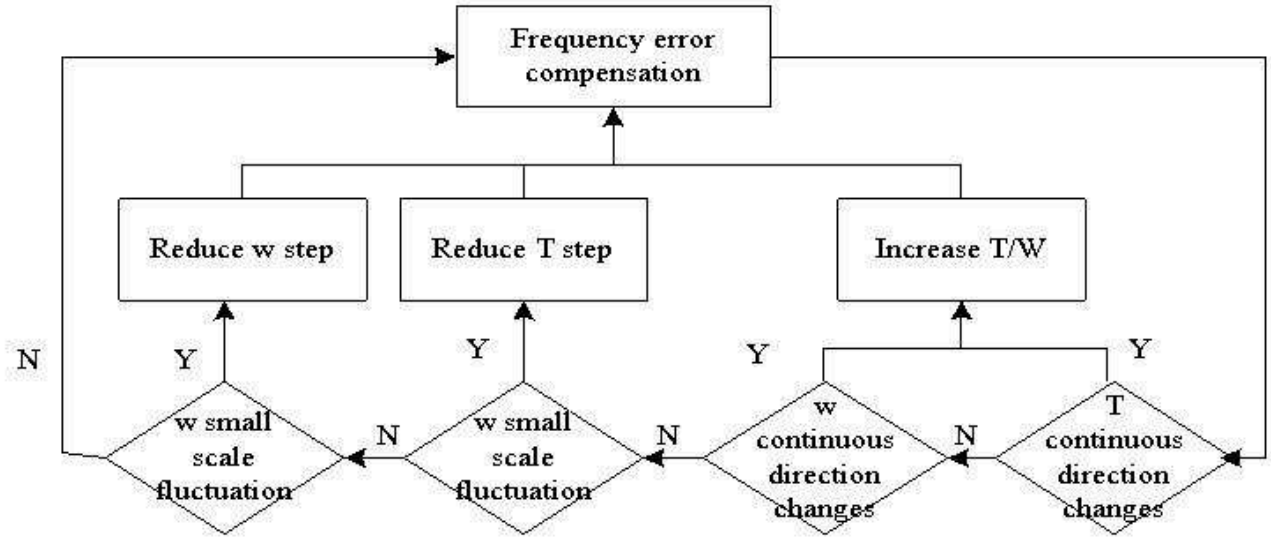

Fig4 Step length adjusting system state transition diagram

When the compensation value to a certain direction continuously increases, the system is still in the tracking status, the iteration step length need to be increased to reduce the iteration times; Compensation value fluctuate in a small scope, basic synchronization system, reduce the iteration step length needed to increase the tracking accuracy. When caught early, with big iteration step into near quickly achieve synchronization locks; Then, use less iteration step improve the synchronization accuracy.

3 Algorithm performance

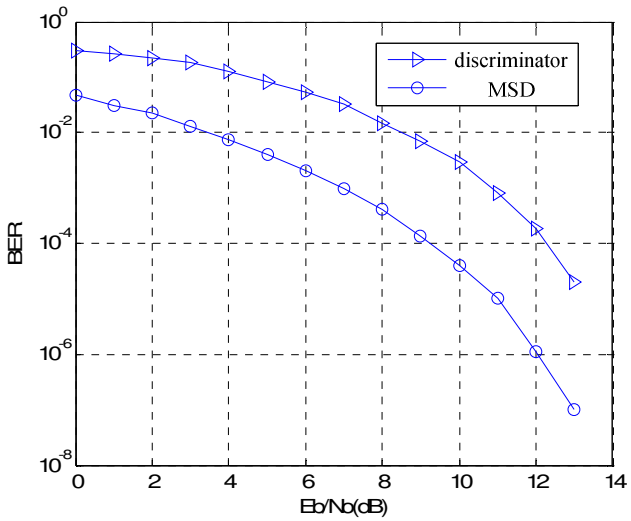

Fig5 The BER curve of MSD method with the conventional demodulation method

In bit error rate of 10^{-4} place[3], MSD technology can get about 3 dB channel gain, in this paper, the baseband pay after rotation MSD technology shows great superiority.

Summary

Through the baseband complex rotating orthogonal MSD technology and the corresponding synchronization method of research and testing shows that the technique can largely improve the performance of the shooting range PCM/FM telemetry system can effectively overcome the traditional technique of frequency discrimination threshold effect.

Keywords: Chirp signal, Fractional Fourier transform (FRFT), parameter estimation, peak searching

Abstract. Chirp signal has been used widely in radar signals, and the Fractional Fourier transform is one of the most effective tools to analyze Chirp signal. In this paper, the concept of FRFT and the estimation theory of Chirp signal are introduced firstly. Then, we study three Chirp signal detection algorithms based on character of Chirp signal energy concentrated in a certain FRFT domain. Finally, in order to test the estimation abilities of the frequency modulation rate and the central frequency of FRFT to Chirp signal, and compare the operation time of parameters estimation under different SNR of the three algorithms, we simulate performance of the Three methods, and the final simulation results show that the three method have remarkable capabilities of detecting Chirp signal with low SNR. In contrast, the two-searching method doesn't need planar search, consumedly reducing the computation cost at the same precision.

Introduction

Chirp signal occurs in modern radar commonly, it has a good time and frequency domain compression feature and excellent Doppler frequency shift characteristics .The routine processing method of Chirp signal in Radar is to doing impulse compression in time domain or frequency domain after go through a band pass filter. Radar receivers detect Chirp signal in receiving signal through threshold determination firstly, and then, extract target echo signal parameters including time delay, Doppler frequency shift and amplitude, this method can acquire higher processing gain and get target parameter accurately. However, when radar is in bad communication environment, especially in active jamming environment, the echo signal is commonly with low SNR, and conventional methods of detection and parameter estimation for these LFM signal is very difficult. Hence, it is an essential research subject of detecting and estimating the echo signal parameters with low SNR condition accurately and quickly.

For a long time, many scholars put forward corresponding methods to LFM signal detection and parameter estimation, Djuric P M and Barbarossa S solved the problem by using maximum likelihood estimation method to solve this problem, however, this method is with too large calculate amount, and make it difficult to put the algorithm into project implementation[1-2]. Haimovich A M took advantage of short time Fourier transform (STFT) and wavelet transform (WT) algorithm to the Chirp signal extimation, but the STFT is a very narrow window and WT time window width changes affect the resolution of the time-frequency domain[3].in additional, Rao P introduced Wigner Ville distribution of Chirp signal parameters estimation method[4], because of the cross terms obsession of Wigner Ville distribution in processing multi-component Chirp signal, therefore, this method is not ideal as well. So it is exigent to find a new fast effective Chirp signal detection and parameters estimation method.

1 Fractional Fourier transform

FRFT is a kind of generalized Fourier transform. it can be interpreted as signals in the representation domain which is generated by time-frequency plane circumrotate a certain Angle circling origin counterclockwise. When rotation Angle is 0, the FRFT result of Chirp signal is itself; when rotation Angle is π, then the FRFT will change into traditional Fourier transform. FRFT was

come up with point of characteristic value and characteristic function in form of pure mathematics by V.Namias in 1980[5], and then, Mcbride and Kerr studied it deeply and build a strict FRFT definition in mathematics. FRFT of a Time domain signal $x(t)$ is defined as

$$X_p(u)=\left\{\mathcal{F}^p[x(t)]\right\}(u)=\int_{-\infty}^{+\infty}K_p(u,t)x(t)dt,\quad 0<|p|<2,\quad 0<|\alpha|<\pi$$

$$=\begin{cases}\mathrm{B}_\alpha\int_{-\infty}^{+\infty}\exp(j\dfrac{t^2+u^2}{2}\cot\alpha-\dfrac{jtu}{\sin\alpha})x(t)dt & \alpha\neq \mathrm{n}\pi\\ x(t) & \alpha=2\mathrm{n}\pi\\ x(-t) & \alpha=(2\mathrm{n}\pm1)\pi\end{cases}\tag{1}$$

Where $\mathrm{B}_\alpha=\sqrt{(1-j\cot\alpha)/2\pi}$, $\alpha=p\pi/2$, and p is FRFT order.

2 Chirp signal detection and parameter estimation based on FRFT

2.1 Two dimension peak searching algorithm

If the rotation Angle is right, Chirp signal will display energy concentration character in corresponding FRFT domain. Hereby, we can take advantage of this feature to detect and estimate Chirp signal parameter. The step is: first, scanning rotation Angle with a step order, doing FRFT transform to the unknown parameters Chirp signal and taking its modulus square, so it will form a two dimension distribution of Chirp signal energy in (α,u) plane; Then, searching the peak value in the two-dimensional plane; Finally, we can estimate the Chirp signal parameters according to the relationship between parameters (α,u) correspond to the peak and initial frequency and the adjustable frequency of Chirp signal.

Chirp signals have a general expression as

$$s(t)=a_0\exp(j\varphi_0+j2\pi f_0t+j\pi\mu_0t^2),\quad \text{-T/2<t<T/2}\tag{2}$$

Where $a_0,\varphi_0,f_0,\mu_0,T$ are amplitude, initial phase, initial frequency, adjustable frequency and time duration. The relationship between Chirp parameters and the parameters (α,u) correspond to the peak value in the two dimension peak searching algorithm

$$\begin{cases}\hat{\mu}_0=-\cot(\hat{\alpha}_0)\\ \hat{f}_0=\hat{u}_0\csc(\hat{\alpha}_0)\\ \hat{\varphi}_0=\arg\left[\dfrac{X_{\hat{\alpha}_0}(\hat{u}_0)}{A_{\hat{\alpha}_0}e^{j\pi\hat{u}_0^2\cot(\hat{\alpha}_0)}}\right]\\ \hat{a}_0=\dfrac{\left|X_{\hat{\alpha}_0}(\hat{u}_0)\right|}{\Delta t\left|A_{\hat{\alpha}_0}\right|}\end{cases}\tag{3}$$

2.2 Two step maximum modulus searching algorithm

In order to improve the real-time performance and reduce calculation amount of Chirp signal detection and parameter estimation, in this section, we introduce a kind of two steps searching algorithm based on FRFT maximum modulus, the idea of algorithm can be divided into the following three steps:

Step 1: doing FRFT for certain Chirp signal on a larger order number step in the range of 0 to 2, and gain a vector of each FRFT order maximum modulus value.

Step 2: searching the maximum value and the minor maximum value, and then calculate FRFT order numbers corresponding to the two values.

Step 3: do FRFT for the Chirp signal between the two orders with smaller FRFT step value and search the maximum value in the two dimensional plane formed by FRFT order and FRFT domain, finally, we can detect and estimate Chirp parameters according to formula (1).

2.3 Pre-estimation algorithm

The idea of Chirp signal parameters estimation pre-estimation algorithm is based on bandwidth limited character of time duration limited Chirp signal. We do Fourier transform for a time limited Chirp signal and acquire its bandwidth from frequency spectrum; Then, we can easily figure out approximation of Chirp rate and initial frequency, so we can gain almost the best FRFT order; Finally, we do FRFT for the Chirp signal around the best FRFT order and gain the best FRFT order through peak searching, then estimate Chirp signal parameter based on the best FRFT order.

3 Simulation analyses

In this section, we compare estimation precision and calculation complexity of the three Chirp signal parameters estimation algorithms through MATLAB simulation. As shown the expression formula of Chirp signal as described above, parameters a_0, φ_0, f_0, k are equal to 1,,256 and -30 respectively, and time duration is between -1 second and 1 second. The simulation result is shown as follow.

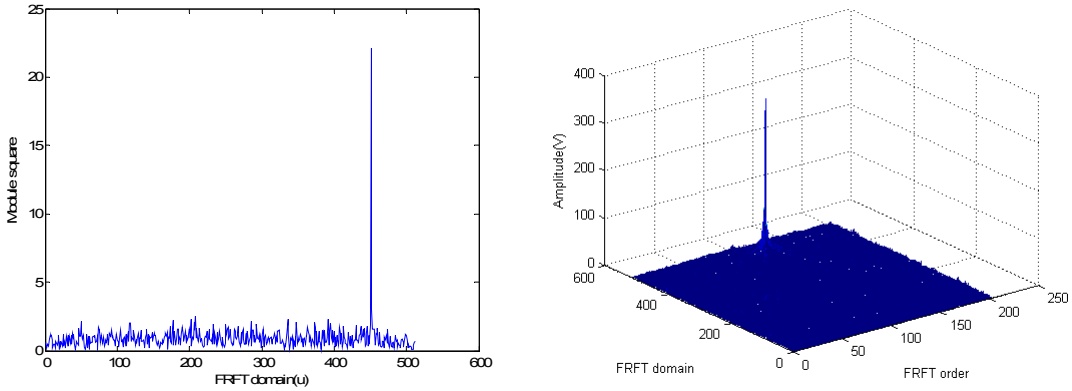

Fig 1 Three-dimensional energy distribution of Chirp signal and its form in best FRFT domain

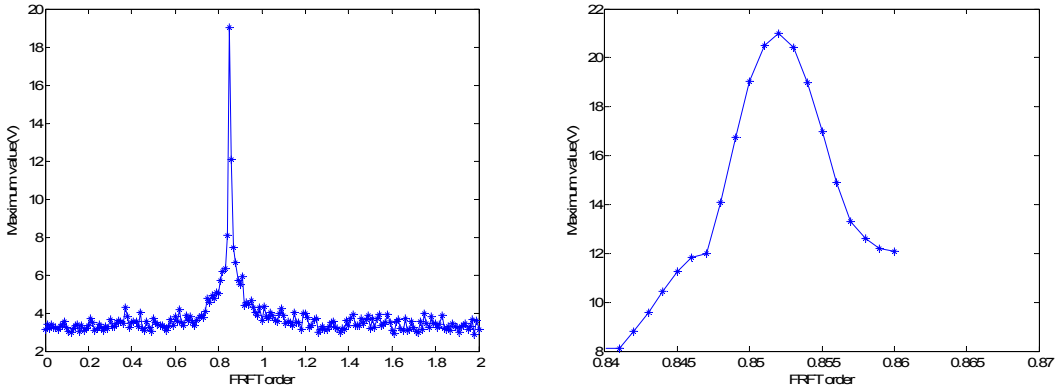

Fig 2 Relationship between maximum value and order in rough searching and refined searching respectively

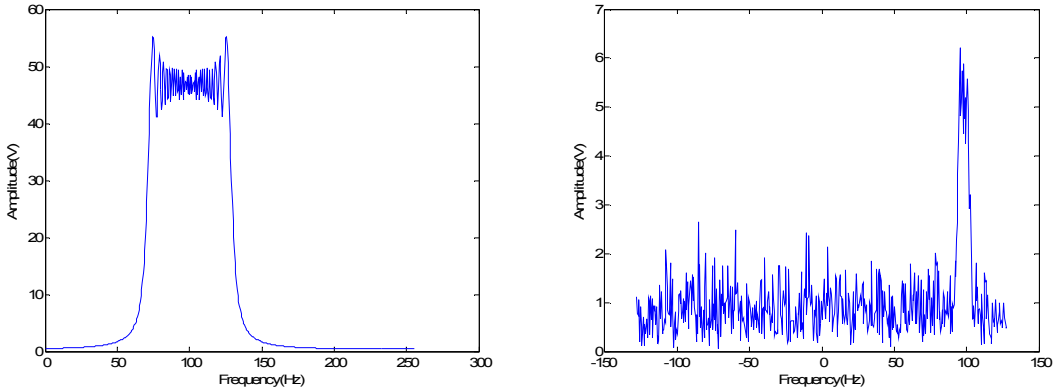

Fig 3 Chirp signal distribution in frequency domain and FRFT domain respectively

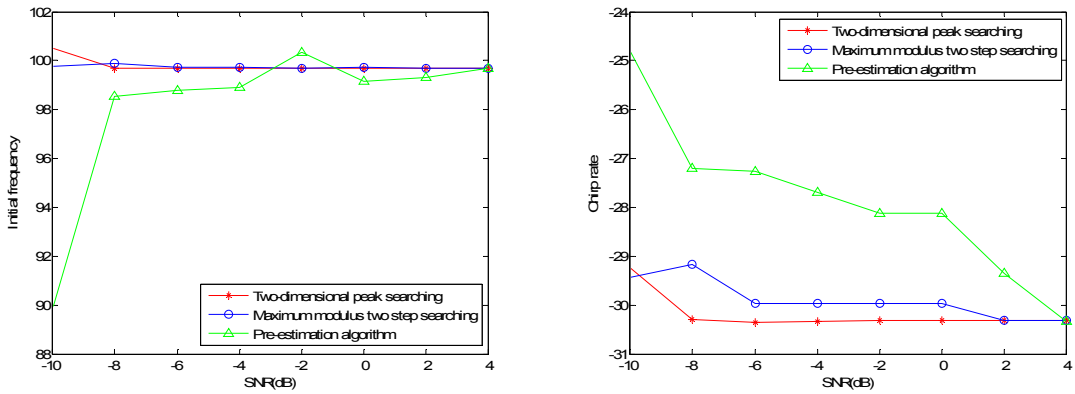

Fig 4 Chirp signal distribution in frequency domain and FRFT domain respectively

According Fig 4, it is easy to conclude that the two-dimensional peak searching algorithm has the best estimation precision, the pre-estimation algorithm is the worst, and performance of maximum modulus two step searching algorithm is close to the two-dimensional peak searching algorithm. However, the calculation complexity of the two-dimensional peak searching algorithm is decuple to the maximum modulus two step searching algorithm. Therefore, In contrast, we consider the two step maximum modulus searching algorithm as the most suitable algorithm in practice.

Summary

In this paper, we take advantage of energy concentration character of Chirp signal in FRFT domain to estimate radar echo signal parameters. Then, we introduce three Chirp signal parameters estimation algorithms based on FRFT. Finally, we compare estimation precision and computation complexity through MATLAB simulation under SNR range from -10dB to 4dB. In contrast, the two step maximum modulus searching algorithm is the most fitness Chirp signal estimation algorithm.

Keywords: MR image reconstruction; group sparse; super-pixel

Abstract. Exploiting the sparsity of MR signals, Compressed Sensing MR imaging (CS-MRI) is one of the most promising approaches to reconstruct a MR image with good quality from highly under-sampled k-space data. The group sparse method, which exploits additional sparse representation of the spatial group structure, can promote the overall sparsity degree, thereby leading to better reconstruction performance. In this work, an efficient superpixel/group assignment method, simple linear iterative clustering (SLIC), is incorporated to CS-MRI studies. A variable splitting strategy and classic alternating direct method is employed to solve the group sparse problem. The results indicate that the proposed method is capable of achieving significant improvements in reconstruction accuracy when compared with the state-of-the-art reconstruction methods.

Introduction

MRI acquisition speed is usually limited by the large number of acquisitions needed along the phase-encoding direction [1]. With the advent of compressed sensing (CS) theory [2, 3], MRI with sparsity-promoting regularization criteria (e.g., ℓ1-based regularization), termed CS-MRI, have gained popularity [4-6]. CS-MRI [4] exploits the sparsity of the signal itself to reconstruct the MR images from far fewer samples than conventional methods require, thus significantly reducing the scan time. However, successful reconstruction from an undersampled MR signal using CS requires the satisfaction of two criteria: (a) the sparsity of the MR imaging introduced by a sparsifying transformation function; and (b) incoherency between the sampling matrix and the sparsity basis.

In the CS-MRI reconstruction, the method used to sparsify the MR images is very important. The most commonly used sparsity bases are predefined transforms, such as the discrete cosine transform (DCT), and the discrete wavelet transform (DWT). When using the above-mentioned sparsifying transforms in the CS-MRI reconstruction, it is often useful to include a Total Variation (TV) penalty as well [4]. The linear combination of total variation and wavelet sparse regularization, known as TVL1 problem, is very popular in many CS-MRI models[4,5], which can be considered as requiring the MR image to be sparse by both the specific transform and finite-differences at the same time. The non-linear conjugate gradient method (NLCG) with a backtracking line-search was first proposed to tackle the TVL1 problem for reconstructing the MR image in Sparse-MRI [4].In order to further enhance the reconstruction quality of CS-MRI, recent studies indicated the necessity of going beyond sparsity and taking into the structure information of sparse signals. In practice, a wide range of MR images are known to have certain "group sparsity" property, that is, the sparsity signals has a natural grouping of its components, and the components within a group are likely to have similar characteristics. The Group Sparse (GS) method has been introduced into one-dimensional signal recovery considering equal or unequal length groups [7, 8]. Experiment results have demonstrated that group sparse methods have advantages over standard CS reconstruction [7]. Usman et al. introduced the k-t group sparse method for dynamic MR images[9,10], which exploited not only the sparsity information as in the conventional compressed sensing, but also the spatial group structure in the sparse representation. Compared with the standard compressed sensing MR image reconstruction,

the group sparse method can improve the spatial and temporal quality of the MR image reconstruction. Typically, the group sparse method comprises three steps: prior information estimation, group assignment, and signal recovery.

Recently, a new super-pixel algorithm based on k-means clustering, simple linear iterative clustering (SLIC) [11], has been proposed for generating super-pixels, which has been shown to outperform other Super-Pixel methods with efficiency in computation and memory usage. In this work, we incorporate the SLIC-based super-pixel generating algorithm to implement the group assignment for a GS-enforced MRI reconstruction method, which is then solved using an efficient alternating direction method (ADM) with mixed $\ell_{2,1}$ regularization[8,12]. We refer to this approach as group sparse reconstructions using super-pixel algorithm, termed as SP-GS method. In order to compare with the state-of-the-art CS-MRI algorithms for reconstruction of the highly under-sampled MR imaging, we conduct extensive experiments to test the proposed SP-GS method.

Theory

Group Sparse Method

Suppose the reconstructed MR image u is partitioned into k groups by the super-pixel algorithm, the group sparse formulation can be described as:

$$\min_u \left\| u^{(g)} \right\|_{2,1} \quad s.t. \quad \left\| F_u u - f_u \right\|_2 \le \varepsilon , \tag{1}$$

where $\left\| u^{(g)} \right\|_{2,1}$ is the mixed $l_{2,1}$ norm defined as:

$$\left\| u^{(g)} \right\|_{2,1} = \sum_{i=1}^{k} \left\| u_i^g \right\|_2 \tag{2}$$

$\left\| u_i^g \right\|_2$ being the l2 norm of the vector of all elements of u assigned to the *i*th group (*i*=1,2,3,…,k).

In this work, alternating direction method (ADM) is applied to solve the group sparse problem in the form of Eq.(1). First, an auxiliary variable v is introduced to transform Eq.(2) into an equivalent problem as follows:

$$\begin{aligned} &\min_{u,v} \left\| v^{(g)} \right\|_{2,1} = \sum_{i=1}^{k} \left\| v_i^g \right\|_2 \\ &s.t. \quad v = u \text{ and } \left\| F_u u - f_u \right\|_2 \le \varepsilon \end{aligned} \tag{3}$$

The augmented Lagrangian problem of Eq.(4) can be formulated as :

$$\begin{aligned} &\min_{u,v} \left\| v^{(g)} \right\|_{2,1} - \lambda_1 (v-u) + \beta_1 / 2 \left\| v-u \right\|_2^2 \\ &-\lambda_2 (F_u u - f_u) + \beta_2 / 2 \left\| F_u u - f_u \right\|_2^2 \end{aligned} , \tag{4}$$

where λ_1, λ_2 are multipliers, and β_1, β_2 are penalty parameters. The multipliers λ_1 and λ_2 are updated in the following way:

$$\begin{cases} \lambda_1 \leftarrow \lambda_1 - \gamma_1 \beta_1 (v-u) \\ \lambda_2 \leftarrow \lambda_2 - \gamma_2 \beta_2 (F_u u - f_u) \end{cases} , \tag{5}$$

where γ_1, γ_2 >0 are step length.

Then, the ADM approach is employed to minimize the augmented Lagrangian problem, Eq.(4), with respect to *u* and *v* alternately[8].

B. Super-pixel based Group Assignment

A simple parameter of SLIC algorithm is the desired number of the approximately equally-sized super-pixels (ns). For grayscale MR image, the clustering procedure begins with ns initial cluster centers $C_i = [g_i, x_i, y_i]^T$, which are sampled on a regular grid spacing, where gi is the grayscale value and (x_i, y_i) is the position of the ith cluster center. To produce roughly equal sized super-pixels, the

grid spacing is set as $S=\sqrt{N/ns}$, and N is the total pixels of the MR image. The next step is to find the nearest cluster center for each pixel. Instead of searching over the entire image as in conventional k-means clustering methods, the SLIC algorithm adopts super-pixel search regions of $2S\times 2S$ pixels around the super-pixel centers, which significantly lessens the number of distance calculations and results in an obvious speed advantage. The distance measure D is an effective way to determine the nearest cluster for each pixel. To combine the grayscale distance d_g and spatial distance d_s between pixel *j* and pixel *i* into a single measure, it is necessary to normalize both distances by their respective maximum distance with in a cluster.

The distance measure D is defined as [11]:

$$D=\sqrt{d_g^2+(\frac{d_s}{S})^2 m^2}\ , \tag{6}$$

where *m* is the weighting parameter between the gray similarity and spatial proximity, and gray distance and spatial distance are calculated as:

$$\begin{aligned} d_g &= \sqrt{(g_j-g_i)^2} \\ d_s &= \sqrt{(x_j-x_i)^2+(y_j-y_i)^2} \end{aligned} \tag{7}$$

Once each pixel has been associated to the nearest cluster center, the cluster centers are adjusted to the mean $\overline{C}=[\overline{g},\ \overline{x},\ \overline{y}]^T$ vector of all pixels belonging to the corresponding clusters. The residual error E between the updated cluster center locations and previous cluster center locations is computed to evaluate the error convergence. The group assignment and update steps can be repeated iteratively until convergence. Finally, a post processing step using a connected component algorithm is designed to reassign the disjoint pixels to nearby super-pixels[11].

Materials and Methods

To compare the NLCG, method in the standard CS-MRI with the proposed SP-GS method, a brain MR image is used to test the reconstruction performance. The Fourier transform reconstructions of the fully-sampled k-space data are shown in Figure 1. To test the algorithms at various reduction factors, the k-space was under-sampled retrospectively. The sampling density of the 2D random pattern approximated the signal energy distribution. This sampling strategy has been widely used for compressed-sensing MR image reconstruction [4,5]. All the measured k-space data f_u are mixed with -20dB simulated Gaussian white noise compared with the maximum of the signal intensity.

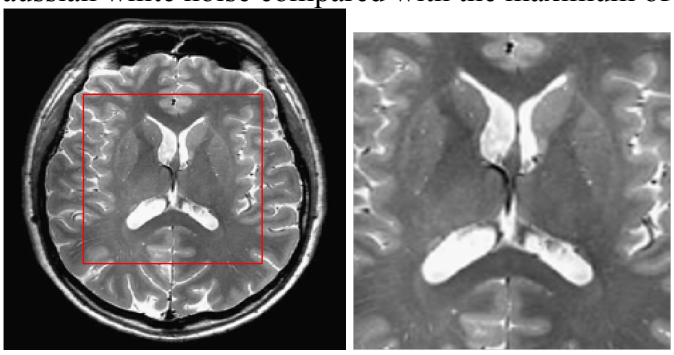

Fig.1 The Brain MR image. Left: Reference image; Right: Zoomed-in of the box in the reference image

The Daubechies-4 was used as the sparsifying transform ψ in the standard CR-MRI reconstruction problem (1), and its regularization parameters α and β are set as α=0.001 and β=0.035 respectively, which were used in the previous work [4,5]. The parameters for ADM-based group sparse method are set as follows: β_1=0.3/<abs(f_u)>,β_2=3/<abs(f_u)> and γ_1= γ_2=1.6, where <·> is the arithmetic average and abs(f_u) are the absolute values of k-space measurements . In the SLIC-based super-pixel generating method, the desired number of super-pixels is set as ns=200; the weighting

parameter between grayscale distance and spatial distance is set as m=10; and the threshold E in the algorithm 1 is set as 10-3. All reconstructions were implemented in the Matlab programming environment (Version 2008a, Mathworks, Natick, MA), and the experiments were performed on a ThinkPad laptop with 2.67 GHz Intel Core 2Duo processor, 3 G of memory and Windows 7 operating system.

To quantitatively evaluate the efficiency and accuracy of the reconstruction algorithms, three indexes were introduced: (i) the Signal-to-Noise Ratio (SNR); (ii) the image reconstruction time. Furthermore, the reconstructed images, zoomed-in regions and their error images (the absolute difference between reconstructed image and the original image) were also compared visually. The error images were magnified twice for better illustration. The SNR and RE were calculated as follows:

$$SNR = 10\log_{10}\frac{Var(u_0)}{MSE(u-u_0)} \tag{8}$$

where MSE is the mean squared error between the reconstructed (u) and the original image (u_0); $Var(u_0)$ denotes the variance of the values in u_0; u is the reconstructed image and u_0 is the original image.

Results

A. Super-Pixel based group assignment

After obtaining the prior information from the MR image reconstructions with 79.46% under sampling (using 20.54% of full data) by using the NLCG method, the simple linear iterative clustering (SLIC) was employed to generate the super-pixels. As shown in Figure 2, it can be found that the components within a group are likely to have similar grayscale values. The computed group numbers of the Brain image is 201.

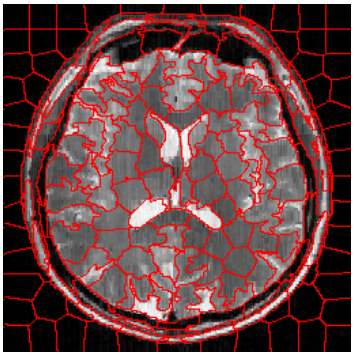

Fig. 2 SLIC based super-pixel method for assigning the groups from Brain MR image reconstruction with 79.46% under sampling by using the NLCG method.

B. MR image reconstruction

The brain image was obtained by scanning a healthy male volunteer's brain with a Bruker 2T whole-body MRI system. Figure 4 and Table 2 show the reconstructed brain MR image with different undersampling rate by using NLCG and the proposed SP-GS methods. For the 79.46% undersampling rate, Figure 4 displays the reconstructions, zoomed-in sections and the error maps, obtained by the use of NLCG method (Figure 3(a)), and the proposed SP-GS method (Figure 3(b)), respectively. As can be seen from Figure 3 and Table 1, the proposed SP-GS method provided better reconstruction quality than the NLCG method at all reduction factors.

Discussion and Conclusion

In this paper, a group sparse method was employed to reconstruct the highly under-sampled MR image. The group sparse optimization promotes group sparsity; however, the mixed $l_{2,1}$ norm

structure and possible grouping irregularity made the $l_{2,1}$ regularization problem more difficult to solve than the conventional l_1-regularized problem in standard CR-MRI reconstruction. simple linear iterative clustering (SLIC) based super-pixel generating method was incorporated to assign the groups. And the brain MR image with different undersampling rates was used to validate the performances of the proposed SP-GS method on reconstruction properties and computational efficiency.

In terms of the reconstruction quality with the three different MR data tested, it can be observed visually that the proposed SP-GS method significantly outperformed NLCG, in the case of 79.46% undersampling k-space data, as shown in Figure 3. Quantitative comparison, as summarized in Table I, suggested that the proposed SP-GS method improved the reconstruction SNR by 5~12dB and reduced the RE by 7%~34% when compared with the conventional CS-MRI reconstruction method.

In this paper, a novel group sparse based algorithm is demonstrated for reconstructing MR image with highly undersampled k-space data. The algorithm applies simple linear iterative clustering to assign the groups in the sparse representation, and then uses the alternating direct method to solve the group sparse problem. The experimental results indicate that the proposed method considerably outperforms the classic CS-MRI reconstruction methods in terms of the reconstruction quality.

Keywords: demodulation, PCM/FM, MSD, synchronization

Abstract. The traditional method of demodulation for PCM/FM telemetry demodulation threshold is higher and the computation of the larger problem, research an orthogonal baseband after rotation, Symbol Detection (Multi - Symbol Detection, MSD) technology: the first frequency under the intermediate frequency digital telemetry signals processing, single sign on orthogonal baseband signal correlation matching, and then apply compound spinning technology to meet at the same time for multiple element symbols at the same time Detection, the purpose of the final design step length synchronization method with demodulation smoothly.

Introduction

PCM/FM telemetry signal demodulation is currently a hot research topic, the present stage space demodulation equipment is mainly used with orthogonal coherent demodulation method method, differential detection method, WD and DSTFT method, etc. However, all these demodulation method has certain limitation, such as orthogonal coherent demodulation needs strict synchronization; Digital FM signal demodulation based on DSTFT and WD algorithm is strong decay resistance, but the computation is too big. Boils down to a little[1] [2], the demodulation threshold causing high above the limitations of demodulation method. To this end, this paper adopts a orthogonal baseband after rotation symbol detection (MSD) method.

1 Traditional algorithms of MSD

Set the remote sensing observation period received can simplify the intermediate frequency signal is expressed as:

$$s(t) = \cos[w_c + f(t) + \theta_1] \tag{1}$$

The received signal with local orthogonal carrier multiplication, respectively after the Hilbert transform of two orthogonal baseband signals (I/Q).

$$R = I + j.Q = \cos[f(t) + \theta_1] - j\sin[f(t) + \theta_1] \tag{2}$$

So the corresponding local signal is also there are 2^N possible.

$$L = \cos[f(t) + \theta_2] + j\sin[f(t) + \theta_2] \tag{3}$$

$$\begin{aligned} R \cdot L &= \cos(\theta_2 - \theta_1) + j\sin(\theta_2 - \theta_1) \\ &= I_B + jQ_B \end{aligned} \tag{4}$$

The formula (5) the product of the result in integral operation within the length of observation, are:

$$M = N_C \cdot I_B + jN_C \cdot Q_B \tag{5}$$

Again to formulas (6) model of the complex signal results of square, get it:

$$S = N_C^{\,2} \cdot (I_B^{\,2} + Q_B^{\,2}) \tag{6}$$

So by the above process can distinguish the receiving signal element of positive and negative. Implementation block diagram is shown in figure 1.

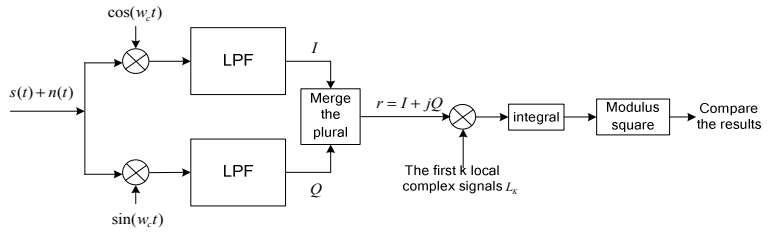

Figure 1 Baseband orthogonal MSD principle block diagram

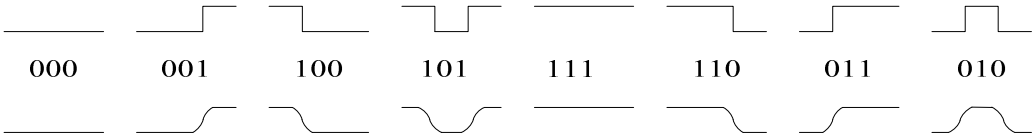

Figure 2 Preset filter before and after eight possible code waveform comparison

Eight of the plural by allowing for $M_{10}(1)$ to $M_{80}(1)$ accordingly plural Angle rotation, get eight different symbol waveform corresponding to different initial phase values of local signal associated with the current signals as a result, $M_{11}(1),\cdots,M_{1n}(1),M_{21}(1),\cdots,M_{2n}(1),M_{81}(1),\cdots,M_{8n}(1)$.

According to the current element time of various local corresponding correlation matching value of the received signal waveform and $M_{10}(1)$ and $M_{80}(1)$ and before 4 codes period have different code to local waveform and the initial phase of the correlation value between the received signal $M_{10}(k),\cdots,M_{1p}(k),M_{20}(k),\cdots,M_{2p}(k),M_{80}(k),\cdots,M_{8p}(k)$ $(k=2,3,4,5)$ .Out of the 128 possible, recent five codes period of approximate correlation value.

$$M_n = M_{7a}(5)+M_{6a}(4)+M_{3c}(3)+M_{1d}(2)+M_{20}(1) \tag{10}$$

2 Cascade type fixed step length synchronization

In the digital information transmission system, the accuracy of the synchronous is the basis of the correctness of the judgment, usually includes carrier synchronization and synchronization code. In the demodulation system, this paper design the cascade type fixed step length synchronizer can accurately fast local signal and the received signal to achieve the same frequency and phase.

First of all, only consider the deviation, will receive medium frequency signal in the form of a index for:

$$r(t) = e^{j(2\pi(f_c+\Delta f)t+\psi(t;z))} \tag{11}$$

At this point, with a maximum likelihood value expressions of deviation are as follows:

$$M = \max\left\{\int_0^{NT}\exp(j(2\pi(f_c+\Delta f)t+\psi(t;z)))s(t;\overline{z})dt\right\} \tag{12}$$

According to the type value of maximum likelihood (12) and the relationship between the deviation curve, the curve within the scope of 0.2 times the code rate on convex characteristics, according to the characteristics of intermediate frequency signal received at the same time A certain step fluctuation frequency processing, for after lifting the frequency of two-way signal to MSD after calculation, set by two way likelihood values for $M_{\max}(\Delta f-\Delta f(n)+k_1 f_c)$ and $M_{\max}(\Delta f-\Delta f(n)-k_1 f_c)$.

The two likelihood value difference, is the measure of synchronizer deviation error measurement, and can be feedback to the loop frequency offset correction to correct deviation loop.Update deviation:

$$\Delta f(n+1) = \Delta f(n) - \frac{e(n)}{|e(n)|}\lambda \tag{13}$$

Considering the influence of time delay below, only the presence of time delay, the presence of delay corresponding to the maximum likelihood expression is:

$$M_{\max}(\overline{z}) = \max\left\{\int_0^{NT}\exp(j(2\pi f_c(t-\Delta t)+\psi(t-\Delta t;z)))s(t;\overline{z})dt\right\} \tag{14}$$

Through (14) can draw the time delay effect on the likelihood value curve, and thus learned that the same curve with the convex properties, therefore, is similar to deviation, can be based on the idea of sooner or later, the door to receive the intermediate frequency signal simultaneously step must be A long time to add and subtract, and after MSD calculation, set by two way likelihood values of $M_{\max}(\Delta t-\Delta t(n)-k_2T)$ and $M_{\max}(\Delta t-\Delta t(n)+k_2T)$. Update time delay compensation value, namely:

$$\Delta t(n+1)=\Delta t(n)-\frac{e(n)}{|e(n)|}\lambda \tag{15}$$

In conclusion, through the analysis of carrier synchronization and code synchronization, design a step length of cascade type synchronizer is shown in figure 3.

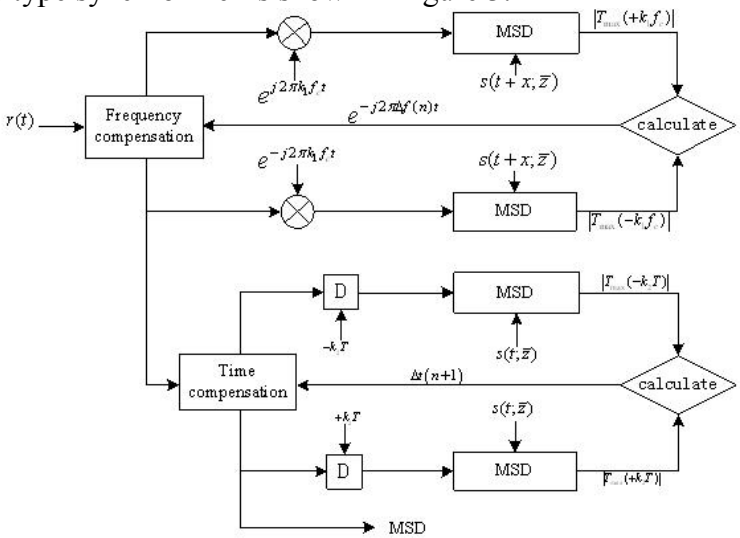

Fig3 Cascade type fixed step length synchronization principle block diagram

According to figure 3 design of synchronization method for frequency offset and time delay of synchronous simulation, get the estimates of variance and the SNR simulation diagram and the different time iteration step length and the relationship between the ber simulation diagram as shown in figure 4 and 5.

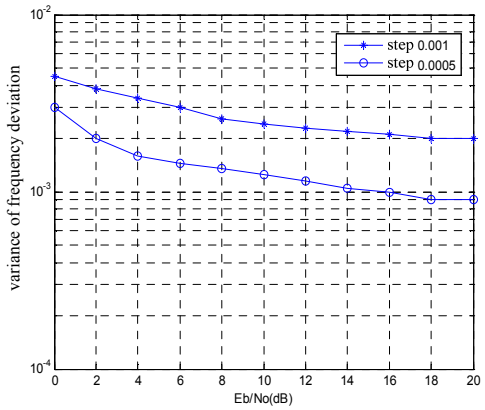

Fig4 Estimates of variance and signal-to-noise ratio

Figure reflects the achieve synchronization state 4, frequency offset estimation variance and the relationship between the SNR, it can be seen that with the improvement of signal-to-noise ratio, increase the stability of the estimates. The figure 5 shows, different time different iteration step length corresponding BER curve, namely under the condition of the same signal-to-noise ratio, different iteration step length error rate, with the decrease of the iteration step length, the bit error rate is reduced,

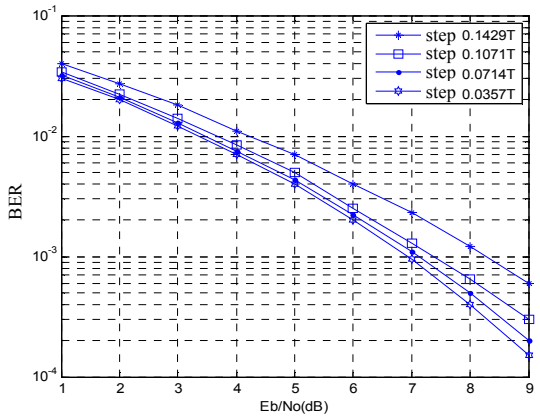

Fig5 The BER curves under different time iteration step length

3 Algorithm performance.

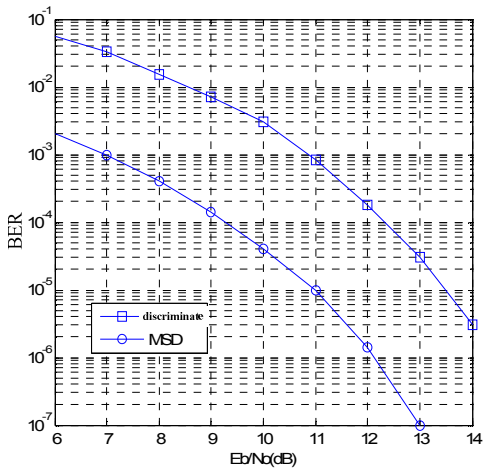

Fig6 The BER curves under different time iteration step length

Through the figure 6 shows that MSD demodulation method based on orthogonal baseband after rotating decoding performance is good, the method is feasible.

Summary

Test results show that the proposed method can effectively break the traditional problem of demodulation method of threshold.

Design of High-Speed Data Collector of blast wave Signal Based on the Post-Trigger Principle

Xinger Tang

Electronic and Information Technology Department, Jiangmen Polytechnic, Jiangmen China

Keywords: post-trigged, blast wave signal, data sampling

Abstract: in view of the incomplete signal and other issues brought by the threshold trigger in the conventional blast wave signal test, this paper designed a post-trigger data high-speed collection method, adopted the ARM7 kernel MCU to complete the design of the hardware scheme and preparation of the corresponding test software, then developed the post-trigger data high-speed collector prototype, and completed the explosive shock wave signal collection through the test. Experiments show that the post-trigger high-speed data collector developed in this paper has the characteristics of simple interface circuit, high precision collection, good reliability, simple operation, which can meet the test requirements of blast wave.

1. Introduction

Blast wave refers to a high-speed high pressure wave spread in the medium (air, water) after the explosion of the explosive, with the characteristics of high transmission speed, instance increase of the pressure on the surface of the wave, the signal test has been the difficulty of dynamic testing technology in weapons industry. Usually, the test of the blast wave test collection is conducted by high-speed data collection instrument, while testing, turn on the collection in advance and then record the way of blast wave signal, which usually will cause the problems of redundant data, difficult to find, increase data processing difficulty and the cost of hardware. But if the data are collected after the threshold signal is triggered, which usually may cause the problem of the incomplete tested waveform caused by the instantaneous uncollected waveform of the pre-trigger point. Other scholars have proposed some solutions, but there are the problems of circuit design complexity and high cost.

Therefore, This paper put forward a data collection instrument design principle based on the post-trigger data high-speed data collection, namely once the collector is turned on, it will be in the normal working state, then it conducts continuous high-speed sampling for the tested analog signal, when the trigger signal comes, it stops the collection after some delay, and then it records the signal at a certain time before and after the trigger point by setting to complete the collection and recording of the waveform of the whole shock wave.

2. Design Principles

Principles of high-speed data collection instrument are usually as follows: the collector is normally in a wait state and it begins sampling measurement only when trigger signal produced by the blast wave arrives. So the weaker the trigger signal of the effective trigger is, the closer the test signal is to the complete blast wave. After all, the blast wave goes before the trigger signal, so no matter how little the trigger signal will produce effective trigger, which cannot obtain the complete shock waves.

2.1 External Trigger Modes and Defects of the Conventional Data Collection

In order to enable the external trigger signal to be effectively triggered, first of all, it is needed to set up a certain trigger condition, when the voltage of the input external trigger signal waveform exceeds the threshold voltage, it will produce the flip level of 0 to 1 or 1 to 0 to start the data collector to collect data.

External trigger signal is usually obtained through a trigger circuit; a simple triggering circuit can be achieved by using a comparator, as shown in Figure 1:

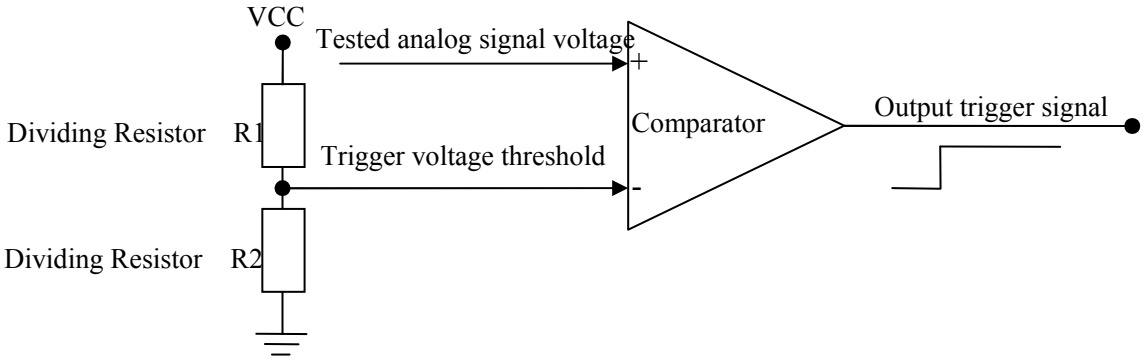

Figure 1: A Simple Trigger Circuit

Trigger voltage threshold can be obtained by the partial pressure of dividing resistor R1 and the dividing resistor R2 to VCC, the supply voltage, the required trigger voltage threshold can be set by changing the resistance ratio of the dividing resistor R1 and the dividing resistor R2.

When the voltage of the input tested analog input signal (i.e. external trigger signal) is compared with the trigger voltage threshold, if the voltage of the analog signal is greater than the trigger threshold voltage, the external trigger signal output by the comparator changes from "0" to "1", the trigger signal occurs a valid triggering, that is, the trigger signal starts the collector to begin sampling.

In response to the uncertainty of the trigger threshold voltage in the actual test situation, a digital analog converter (DAC) can be used to obtain the trigger circuit design of the voltage threshold, as shown in Figure 2.

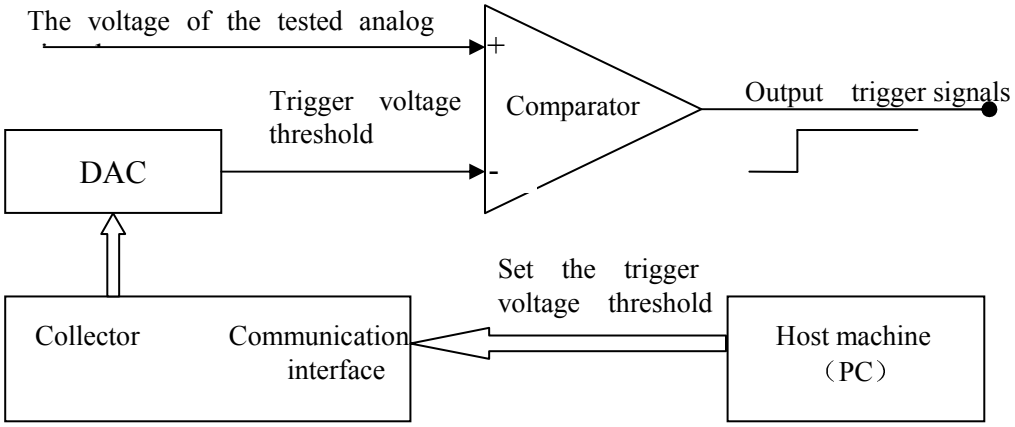

Figure 2: Triggering Circuit Design with DAC

General DAC receives the control and digital input on the host processor from the collector through data / address / control bus, or SPI bus receiver. After the digital quantity to achieve the corresponding required trigger voltage threshold is calculated, the background machine (PC) can send digital quantity to DAC through the UART communication interface to get the DAC output to trigger voltage threshold.

It can be seen that the method through the external trigger signal to start the collector sampling can only collect the waveform which the analog voltage signal is greater than the set threshold trigger voltage, so in order to measure the waveform signal of the complete blast waves as much as possible, it is needed to reduce the trigger voltage threshold as much as possible, but this will cause the occurrence of the false triggering.

2.2 Methods and Characteristics of the Post-Trigger High-Speed Data Collection

Therefore, in view of the above problems, this paper designed a method of post-triggering high-speed data collection, namely with the same external trigger signal, not with the trigger starting the collector to begin sampling operation, but with the trigger causing the collector to stop sampling operation. At this time, the collector usually works in the normal condition, constantly monitoring the input tested analog signal and the external trigger signal. Once the collector is turned on, it will be in the normal working state, the tested continuous analog signal will be high-speed sampled, and the data collected are stored in the collector, being composed of RAM memory in FIFO. After the sampling time of ΔT, the sampling data stored in FIFO will automatically cover before the sampling data before the sampling time of ΔT. Assuming the capacity of FIFO is X bit, the collector uses the ADC of 16 bit precision, the sampling rate is Y MB / sec. ΔT can be calculated:

$$\Delta T = \frac{X}{16 * Y}$$

The test method of post-trigger high-speed data collection is as follows: the same external trigger signal is used to start a delay circuit, after the Δt delay of the circuit. a jump signal is generated to end the high-speed data sampling operation of collector. It can be seen that if $\Delta t < \Delta T$, the sampling data in FIFO will not be covered; if Δt is greater than the time L cost from the beginning of the explosion to the end of the explosion, the collector will can completely collect the blast wave.

In practical design, the special delay circuit can be left out, and the external trigger signal can have direct access to some pin of the main processor, then the external trigger signal can start some timer of the processor, the time of the timer is set to be Δt. Then after the external trigger signal effectively starts the timer, the timer can interrupt after the Δt delay, high-speed sampling requesting the main processor to terminate the high-speed sampling operation of the collector.

3. High Speed Sampling Operation Used in the Measurement of the blast wave Signal

3.1 Introduction to MCU Chip

The main processor adopted in this design is STM32F103ZET6, the processor is the enhanced MCU, 32 bit RISC kernel of the high-performance ARM Cortex-M3 is used, with the frequency of 72M, a built-in high-speed 512K-bytes flash memory and 64K-bytes SRAM, which has a wealth of I / O ports and functions. Including three 12-bit precision A / D converter ; 4 16-bit general timers; 2 PWM timers; it also has a variety of communication interfaces, including two I2C bus interfaces, three SPI interfaces, two I2S interfaces, an SDIO interface, 5 USART / UART interfaces, a USB interface and a CAN interface. Meanwhile, the chip also integrates a FSMC module, which has four chip selective outputs, which support PC Card / CF card, SRAM, PSRAM, NOR and NAND.

3.2 Hardware Design

The overview of the working principle and hardware design of the high-speed post-trigger data collector using STM32F103ZET6 as the main processor is shown. After the signal conditioning of the tested analog signal, trigger signal is separated and be input into the STM32F103ZET6 analog sampling channel. STM32F103ZET6 achieves external RAM expansion via data /address /control bus.

As when the collector conducts high-speed data collection, the sampling data cannot be transmitted in real time, but chronologically stored inside the FIFO of the external SRAM. Only after the end of sampling, a host computer can be used (i.e. a PC in background services) to send commands to the collection via UART and other communication interfaces, taking the sample data existing in the RAM of the external collector.

3.3 Realization of the Function of Post-Trigger

The function of post-triggered of the collector can be realized by regarding one of the STM32F103ZET6 ADC channel to be simulated into watchdog, namely, one of ADC of the analog watchdog accurately monitors the external trigger signal, and the other ADCs collect the voltage of the selected and input analog signal.

When the external trigger signal monitored by the analog watchdog ADC exceeds a preset threshold, the STM32F103ZET6 will generate an interrupt signal to end the ADC sampling operation. An obvious advantage of such the ADC analog watchdog to monitor the external trigger signal is that it can conveniently precisely set the triggering voltage threshold according to the level of error of the actual external trigger signal, the sampling duration and anti-interference, accurate trigger voltage threshold setting of external trigger signal so as to facilitate the adjustment, be conducive to the collection of the sampling data of the complete waveform.

4. Conclusions

This paper used an ARM7 kernel MCU, developed a "post-trigger high speed data collector". The collector realized the functions of timely effectively and completely recording the explosion process by delaying the external trigger signal to end the working mode of the sampling process. And its interface circuit is simple with high precision, which is very suitable for the measurement of the explosion process, and has the widespread application prospect.

On Matlab's Simulations in Underground Mobile Multipath Channel

Jingxin Wei

NCIST Teaching Affairs Department，Bejing East, Yanjiao 101601

Keywords：Channel model, Simulation, multipath interference

Abstract: In underground channel environment, features of wireless mobile channel and channel modeling are discussed, and methods of calculating wireless channel model parameters by adopting even-interval tapped delay wire model are proposed. On this basis, Matlab simulation are carred out, whose results serve as theoretical foundation and criterion for further study of underground wireless communication system.

1 Features of communication in underground mine

The paths covered by signals from the transmitter to the receiver are called channel. In underground wireless communication, wireless waves are transmitted in non-free tunnel with frequent reflection, refraction and scattering. The underground situation is specifically complex due to the rugged seam around the wall and the tunnel-filled supports, electromechanical equipments, metals, power line, dust, and humid air, etc. Electromagnetic waves are transmitted with multiple refractions, reflection and scattering, making the signals reaching to the receivers the synthesis of multipath signals, which is called multipath effect. Multipath transmission will result in the frequency selective fading and delay expansion of received signals, leading to intersymbol interference, which affects the quality of communication directly. As a result, the electromagnetic waves can only be transmitted as far as hundreds of meters in mine tunnel, while the underground tunnel has an average length of several thousands meters, or even as long as ten thousands of meters.

Invisibility is caused by the curved floor and roof in the tunnel and working face, as well as the various kinds of varvature formed by directional changes of coal and rock horizontally. Wireless communication of invisibility greatly reduces the transmission distance of wireless signals in the tunnel and working face.

Therefore, the tunnel effect, limited space, distance and invisibility of underground transmission of the electromagnetic waves make it differ from the surface communication.

2 Underground channel model

The received signal of dispersed multipath channel can be represented[3] [4] :

$$y(t)=\sum_{n}\alpha_n(t)s(t-\tau_n(t)) \tag{1}$$

Where $s(t)$ is band pass received signal, $\alpha_n(t)$ is attenuation factor of Number n path, $\tau_n(t)$ is the corresponding transmission delay. By low pass equivalent effectivity, $s(t)$ can be represented:

$$s(t)=\mathrm{Re}\left[\tilde{s}(t)e^{j2\pi f_c t}\right] \tag{2}$$

$$y(t)=\mathrm{Re}\left\{\left(\sum_{n}\alpha_n(t)e^{-j2\pi f_c\tau_n(t)}\tilde{s}(t-\tau_n(t))\right)e^{j2\pi f_c t}\right\} \tag{3}$$

Then the envelope of attainable output signal is:

$$\tilde{y}(t)=\sum_{n}\alpha_n(t)e^{-j2\pi f_c\tau_n(t)}\tilde{s}(t-\tau_n(t))=\sum_{n}\tilde{\alpha}_n(t)\tilde{s}(t-\tau_n(t)) \tag{4}$$

(4)4indicates that multipath channel can be presented by $\tilde{c}(\tau;t)$, time-varying low pass equivalent impulse response:

$$\tilde{c}(\tau;t)=\sum_{n}\tilde{\alpha}_n(t)\delta(t-\tau_n(t)) \tag{5}$$

Where $\tilde{c}(\tau;t)$ refers to the channel response of $t-\tau$ -added impulse at the time of t.

Each path in the discrete multipath channel is commonly considered as the product of numerous scattering components, therefore, the tap of each path is regarded as one complex Gaussian random variable. In real channel simulation, it is commonly assumed that there a finite number of taps and the number is decided by the channel's delay extension value. To be simple, channel character is assumed to fit in with the character of WSSUS.

$$\tilde{g}_n(t)=\int_{-\infty}^{\infty}\tilde{h}(\tau;t)\left\{\frac{\sin(2\pi B(\tau-nT))}{2\pi B(\tau-nT)}\right\}d\tau \tag{6}$$

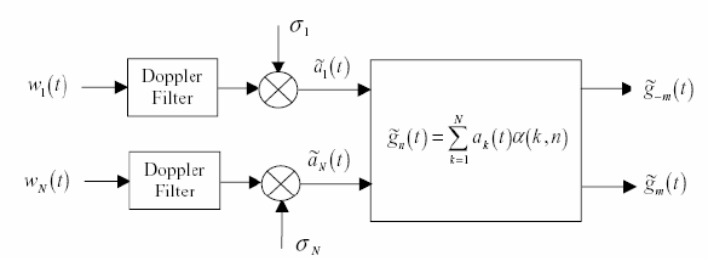
$$\tilde{h}(\tau;t)=\sum_{k=1}^{N}\tilde{a}_k(t)\delta(\tau-\tau_k) \tag{7}$$

Where the impulse response of discrete multipath channel is $\tilde{h}(\tau;t)=\sum_{k=1}^{N}\tilde{a}_k(t)\delta(\tau-\tau_k)$ Therefore,

$$\tilde{g}_n(t)=\sum_{k=1}^{N}\tilde{a}_k(t)\sin c\left(\frac{\tau_k}{T}-n\right)=\sum_{k=1}^{N}\tilde{a}_k(t)\alpha(k,n) \tag{8}$$

Where the envelope of $\alpha(k,n)=\sin c\left(\frac{\tau_k}{T}-n\right)$, $\alpha(k,n)$ decreases with increasing $|n|$. So the number of TDL's model taps can be described as $|n|\le m$, where $m>>T_{\max}/T$. When the maximum of delay expansion is within 3-4 symbol periods, the number of TDL taps is less than 20.

Table 1 TDL model of even interval



As Table 1 indicates, after input signal $w_1(t)\cdots w_N(t)$ (complex Gaussian random process with zero mean, unit variance) passes through the Doppler filter, $T^2p(nT)=\sigma_n^2$ is achieved, and then Doppler power σ_n, which is multiplied by output of Doppler filter to get $\tilde{a}_1(t)\cdots\tilde{a}_N(t)$, leading to $\tilde{g}_1(t)\cdots\tilde{g}_n(t)$, the tap coefficient.

3 Simulation of underground multipath channel

The underground supports, electromechanical equipments, rugged seam, humid air and dust leave no room for direct path between the transmitter and the receiver of wireless devices. So, underground wireless channel accords roughly with the character of Rayleigh channel. According to the documents, underground channel obeys the channel model of exponential decay, whose power delay spectrum decreases exponentially. The power delay spectrum of this model can be shown as:

$$p(\tau)=1/\tau_d\exp(-\tau/\tau_d) \tag{9}$$

To conclude, according to the data in the documents, the following underground wireless multipath channel model can be made:

Table 1: Channel model 1
(rms delay expansion=100ns)

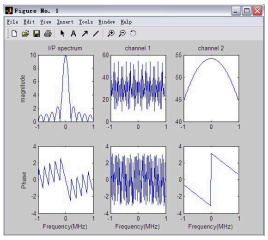
path	delay（ns）	Average powerdB）
1	0.0	0.0
2	50.0	-1.6
3	150.0	-4.7
4	325.0	-10.1
5	550.0	-17.1
6	681.9	-21.7

Table 2: Channel model 2
(rms delay expansion=18ns)

path	delay（ns）	Average power（dB）
1	0.0	0.0
2	50.0	-9.4
3	100.0	-18.9

According to the data in the table, simulation is made as follows:

Table 2 Input spectrum and transfer function under two delays



In Table 2, the upper line is magnitude function, while the lower line is phase function. The first column on the left shows that output spectrum is mainly distributed within the zone of [-200KHz,200KHz]. As to channel 2 (the right column), in this zone the magnitude of transfer function is almost flat and the phase of it is basically linear. So, channel 2 will lead to slight distortion, and this kind of channel is termed as flat fading channel. For channel 1 (the middle column), in this interval, the magnitude of transfer function is non-flat and the phase of it is non-linear. So channel 1 will suffer from severe distortion, indicating that underground channel is frequency selective fading channel. The change rate of transfer function (for specific frequency) is proportionate to the delay expansion — the bigger the delay expansion, the quicker the change rate of transfer function.

4 Conclusion

Considering the features of underground channel environment, this paper makes channel modeling and establishes the channel model according to the underground channel features. Moreover, computer simulation is carried out, laying theoretical foundation for further study on underground wireless communication system.
